ENCYCLOPÆDIA BRITANNICA.

Boring. **B**ORING, generally speaking, is the art of perforating a solid body. In the present article we propose to give some account of the boring of CANNON, of CYLINDERS, of MUSKETS, of PORTLAND STONE, of ROCKS, and of WOODEN PIPES.

Cannon. 1. BORING OF CANNON is performed by placing the cannon on an axis, which is turned by a very strong power, whilst a steel cutter, in form of a drill, is pressed against the metal, and excavates the cylindrical cavity which is required. Boring may be considered as a branch of the art of turning, which, in general, is the formation of cones, cylinders, and other figures that have an axis, by making a straight line or curve revolve round the axis on which the material is fixed, or by making the material revolve whilst the generating line remains at rest. In turning bodies of no great degree of hardness, and where it is required to take off only a small portion of the surface at once, a small power is sufficient to put the turning machine in motion; and the longer the edge of the cutter which is applied to the metal is, and the harder the metal, the greater force is required to turn the machine.

Cannon, at first, were frequently made of bars of malleable iron, placed longitudinally, and these bars covered with iron hoops, the whole welded or brazed together. Ordnance of this construction was not sufficiently strong to resist the explosion of the powder, and did not admit of the cylindrical cavity being formed with much accuracy. Its use was, therefore, gradually laid aside, and guns of cast-metal were employed. And before the casting of cannon became general, guns of cast-metal were reserved for the most important situations; thus the ships of the admiral and vice-admiral alone had cast-metal cannon, the other ships of war being armed with wrought-iron guns only.

Copper, without mixture, has been employed to cast guns, as appears from two large cannon made in the time of Henry VIII. and bearing his name, in the armoury of the Tower of London. But the only two materials now used for cannon are bronze, which is a mixture of copper and tin, and cast-iron. In modern times the use of cast-iron cannon has become more general, as that metal has the advantage of not being softened by the heat of the inflammation of the powder; whereas brass guns, when fired many times in rapid succession, become heated so

VOL. V.

nearly to the melting temperature of the metal, that the muzzle of the gun droops. Boring.

The first cannon made of cast-metal were cast hollow, with a cavity as nearly cylindrical as could be executed by casting. The surface of this cavity was then smoothed on a boring machine by steel cutters set in a copper head, and disposed so as to describe a cylinder terminated by a half spheroid. These cutters (in French *alézoirs*, and the operation *alézer*) are represented in the French *Encyclopédie*—*planches, Fonte*. This method of making guns has long been laid aside on account of the holes and inequalities in the cavity thus formed, and the difficulty of casting the cavity so as that its axis shall coincide with the axis of the piece. Cannon are now always cast solid, and the cylindrical cavity is formed by boring in this solid mass.

The power employed for boring cannon ought to be in proportion to the hardness of the metal of which they are composed, and to the size of the pieces. For the boring of guns of brass, as it is called, that is, a metal composed of ten parts of copper, one of tin, and two of brass, or of these metals in other proportions, a metal softer and more easily bored than cast-iron, horses are frequently employed as a moving power; but the strong moving powers of water or steam must be had recourse to for boring large guns of cast-iron, which is the material used for making the largest guns now in use, and is also the hardest substance used in their manufacture. Indeed some kinds of cast-iron are too hard to admit the action of the borer; and for the making of guns it is necessary to melt pig-iron of different qualities together, in order to have a metal that shall possess no more than the required degree of hardness.

The quality of pig-iron is known by the appearance of its surface, but more decisively by the appearance which its fracture presents. To obtain this fracture, a man takes one end of a pig in each hand, and lifting it as high above his head as he can, throws it with force, so that the middle of the pig shall fall across another pig placed on the ground. In this way the pig thrown down is broken. Soft or grey pig-iron, which is the most valuable, breaks with difficulty, and the surface of its fracture is of a grey colour, composed of pretty large crystalline grains. Hard or white pig-iron breaks easily; the surface of the fracture is white, and not sensibly granulated, the grains that compose it being small. The pig-iron here

Boring. spoken of is that smelted by the coak of pit-coal. Pig-iron smelted with charcoal of wood has a fracture of a different appearance, sometimes lamellar, like the fracture of metallic bismuth. Formerly guns used to be cast from the blast furnace; that is to say, immediately from the ironstone. This was attended with uncertainty in respect to the nature of the metal; for the nature of the metal given by the blast-furnace varies frequently and suddenly, from causes either unknown, or not under the command of the iron-master. For this reason guns are no longer cast from the blast-furnace, but pig-iron already formed is taken, of such qualities and in such proportions as to form a metal neither too soft nor too brittle and hard for guns. The different kinds of pig-iron thus selected are melted together in a furnace, called in iron manufactories an *air-furnace*, and by some writers a *reverberatory furnace*, by the flame of pit-coal; the flame being impelled by a strong current of air produced by the rarefaction of the air in a chimney of thirty or forty feet in height. The column of the atmosphere of which the air in the chimney makes a part being lighter than the unrefined columns of the atmosphere next it, its equilibrium with these columns is destroyed. The neighbouring columns, therefore, rush through the grate of the furnace, which is the only aperture by which they can attain the bottom of the rarefied column; and they carry the flame of the coal against the pig-iron, which is thereby brought into fusion. From the iron thus fused only one large gun is cast at a time, the furnace not being capable of melting more metal than is requisite for that purpose.

The gun is cast with two appendages, which are to come off before it is finished and ready for use. The one is a square piece beyond the cascabel, for fixing the gun so as to revolve with the axis of the boring-mill; and the other is the head.

The head in cast-iron cannon is a mass of cast-iron two or three feet long, and somewhat bell-shaped. It is a prolongation of the mass of metal beyond the muzzle ring, and, in the position in which the gun is cast, the head is the top of the whole mass, the square beyond the cascabel being the lowest part. After the metal has cooled, the upper surface of the head is cavernous, as is the case with the surface that is uppermost during the casting and cooling of any large body of cast-iron. The sides of the cavities in the head are frequently formed of cast-iron crystallized in a fern-leaf form. The intention of the head is to prevent these cavities, which are formed most abundantly at the upper surface of the cooling cast-iron, from forming in the gun itself. But, notwithstanding the precaution of casting the gun with a large head, and of mixing proper kinds of cast-iron in the air-furnace, it frequently happens that small cavities occur in the guns.

The gun with its head being cast and allowed to cool, it is conveyed to the boring-mill, where the head is to be taken off, the cylindrical cavity or bore is to be formed, and the outside of the gun is to be turned. Formerly the boring of guns was done in an upright position; the gun being placed above the boring-bar, was fixed in a frame sliding vertically in grooves. This frame was suspended on each side by a block and tackle, and the end of each of the two ropes was wound round a windlass. By turning these windlasses the gun might be raised or lowered, and by this means might be allowed either to press with its whole weight on the boring-bit, or with any part of its whole weight. A figure of this apparatus may be seen in the French *Encyclopédie*—planches, *Fonte*. Another vertical apparatus for boring cannon is represented in Rinman, *Bergwerks Lexicon*, Stockholm, 1789, tab. iv.

The practice which has long been followed in this country is to place the gun horizontally in the boring-mill; and

it is fixed on the axis of the mill by means of the square piece at the cascabel. **Boring.**

In a boring-mill constructed by Smeaton, one gun is placed on the horizontal axis of the water-wheel itself, and, consequently, revolves with the same velocity. On this same axis is a toothed wheel with seventy-eight teeth, which works two wheels, one placed on each side of it, and each having twenty-nine teeth. On the axis of each of these a gun is placed; their power is $\frac{1}{10}$ ths of the power of the centre wheel. (See Smeaton's *Reports*, vol. i.) On the axis where the power is least, smaller sized guns are bored; on the axis of the greatest power the large guns are bored. A crane, movable on a vertical axis, with a sweep that extends over all the carriages, with a tackle hanging from its beam, and wrought by a windlass, serves to place the gun on the carriage where it is to be bored, or to remove it from one carriage to another if required; and afterwards, when the gun is bored and turned, the crane serves to remove the gun from the boring-mill.

The gun, when placed on the machine, has the square at the cascabel fixed in a square iron box (G, Plate CXI. fig. 5) on the axis. This box has a screw passing through each of its sides, and by the operation of these screws the square of the gun is adjusted, centred, and fixed; the chace of the gun is also fixed in a collar N, in which it is to revolve. (The collar in the figure is represented too near the muzzle ring.)

The axis on which each gun is fixed may be set in gear, or put in connection with the revolving axis of the machine, so as to move round with it; or taken out of gear so as to remain at rest, although the other parts of the machine continue in movement. There are various methods of doing this. One is given by Smeaton in the work above cited. After the gun is fixed on the axis, and before beginning the operation of boring, the head, which has been described above, is cut off near the muzzle ring. For this purpose the gun is set in gear so as to revolve on its axis with the moving power; and a bar of steel, in shape and size like the coulter of a plough, is applied at right angles to the axis of the gun. The narrow side of this bar is sharpened to a cutting edge, so that it has the form of one tooth of a very large saw; and this cutting edge is opposed to the direction of the revolving motion of the gun, and held strongly on to the gun by a screw pressing on the bar; the cutter takes off an angular portion at right angles to the axis, till the cylindrical part connecting the head with the gun is so much diminished, that the head is made to fall off by the blow of a hammer applied on it. In brass guns, cast with a core, the head was sawed off by hand with a blade of steel, whose edge was toothed as a saw, while the sides were toothed as files. See the French *Encyclopédie*—planches, *Fonte*.

A great degree of heat is generated by the violent friction of the steel-cutter on the cast-iron during the operation of cutting off the heads of guns. The quantity of this heat has been estimated by Rumford in one of his *Essays on Heat*.

After the head is taken off, the workmen proceed to bore the gun. This is done by exposing the revolving gun to the action of a steel-cutter, fixed on the end of a bar, which bar is placed on a carriage, and impelled continually towards the gun. The operation of boring is done on the same axis on which the head was cut off, if the power be sufficient; if not, the gun is removed, by means of the crane, to an axis, where it is made to revolve by a stronger power.

The boring-bar is fixed on a carriage sliding in iron grooves, which are truest when made triangular. The carriage, which, in the apparatus represented at fig. 5, consists merely of the bar on which the rack is, is pressed

Vertical boring.

Horizontal boring.

Boring. forward by a pinion P, whose gudgeons are on a fixed frame BB; and this pinion works into a rack R. The axis of the pinion has mortised holes in it, through which one end of a lever L is passed; and the other end of this lever is loaded with a weight W, which causes the pinion to propel the carriage and boring-bar towards the gun. In many boring-machines there are two pinions on the same axis, acting on two racks; in others, the carriage is propelled by two upright levers, on the end of one of which acts a weight, hanging from a rope, that passes over a pulley; the lower end of the upper lever acts on the upper end of the lower, whilst the lower extremity of the lower lever presses forward the carriage. This method, which is free from any inequalities that may arise from the teeth of the rack, is figured by Smeaton in his *Reports*, vol. i. p. 396. Another method of propelling the carriage of the boring-bar, is by a screw acting on the end of the carriage. See Meyer in the *Transactions of the Academy of Stockholm*, 1782, tab. ix.

The boring-bar is a very strong piece of wrought iron, of less diameter than the intended calibre of the piece, in order that the boring dust or shavings detached by the cutter may be got out. The boring-bar is increased in diameter near the end, for some inches, see fig. 6, B; in this part there is a superficial groove for receiving the sides of the steel-cutter or bit, which is to be firmly fixed in the bar. The bit T, fig. 6, is made from a rectangular piece of a steel bar, in which the two upper angles are cut off obliquely, so as to form two cutting edges like an obtuse-angled drill; the side of the rectangle, opposite to the point of the drill, is then hollowed out in the form of a pigeon hole; and this hollow fits into and embraces the solid part of the boring-bar, whilst the sides of the pigeon hole fit into the grooves of the bar. The point of this obtuse-angled bit is pressed against the revolving metal of the gun, by the force which propels the boring-bar; and the edges coming in contact with the revolving metal, a conical cavity is produced; so that, by taking off successively a multitude of similar shells or shavings, the cylindrical bore, with a conical termination, is formed. The diameter of the pointed bit first used must be less than the intended calibre of the piece, as the boring is to be repeated again at least once, in order to make the internal cylindrical surface as smooth as possible, by taking off any inequalities that have been left by the first cutter. In finishing the bore, a cross bit may be employed. It is a rectangular piece of steel, ground to a cutting edge at each end, and put through a hole in the boring-bar, in which it is fixed. The edges of this cutter, in revolving, describe a cylindrical surface. After the cylindrical surface of the bore is made sufficiently true, and of the required calibre, a bit without a point, and rounded off to the desired curve, is used to form the bottom of the chamber.

Some recommend that the boring-bit for cast-iron should have its cutting edges brought to an acute angle, by being filed hollow; but in this case the two edges cannot be brought into one point; for the obtuse-angled edge formed by the thickness of the metal of the bit joins the two cutting edges crossways, and forces itself forwards by being near the centre, requiring, however, a considerable pressure. These hollow-edged bits are not so well adapted to continuance of grinding as the plain ones, but they make amends by their much less frequently wanting sharpening. It does not appear, however, that these hollow-edged bits have been found advantageous in gun-boring.

The howitzer appears to have had its origin in Germany. This piece of ordnance, the mortar, and the coronade, in all of which the diameter of the chamber for the powder is smaller than the diameter of the rest of

the bore, are first bored all through, nearly to the intended calibre of the chamber, and then that part of the bore that requires it is enlarged.

The cutters in gun-boring become magnetic, in consequence of being continually rubbed in the same direction, so that the boring dust is seen adhering and hanging from their edges when they are withdrawn from the gun.

It is required that the bore shall be a cylindrical cavity whose axis coincides with the axis of the gun: for this purpose, care must be taken to place the axis of the boring-bar, and that of the gun, both in one horizontal line, and it is requisite that these two lines continue in this position during the whole operation of boring. The centring of the boring-bar for this purpose requires to be done by an experienced workman, and an accurately-constructed boring-machine is necessary for the continuance of the right position.

Whilst on the axis of the mill, the gun has a smooth outer surface given it by turning tools, which are applied in the way usual in turning metals; a wooden gauge, or cut-out profile, of the gun, with its intended mouldings, being applied to know when the turning has been continued to a proper depth. When this is done the gun is taken out of the boring-mill; the square at the cascabel is cut off by the chisel; and the trunions, and other parts which are not susceptible of being turned, are dressed by the chisel. The cyphers and arms which had been cast on the gun are finished by the chisel.

A cannon is said to constitute the *ultima ratio regum*, the last argument that governments have recourse to; and even this severe kind of argument has sometimes been embellished. Amongst ornamented cannon, the brass three-pounder in the Tower, brought from Malta, is a masterpiece; it is covered with carving in a good taste by a sculptor of Rome.

The touch-hole is drilled by stock and bit, or by drill and bow; the drill being propelled by a lever placed on a carriage, movable on wheels. A figure of this apparatus is given in the *Encyclopédie*—planches, *Fonte*. Another apparatus for this purpose is figured in Rinman, *Bergwerks Lexicon*, table xiv. fig. 9, 10. See also Monge, *Description de l'Art de Fabriquer les Canons*, in 4to, Paris, 1794. This work was published by order of the revolutionary government, and distributed to the iron-masters and founders in different parts of France, for their instruction. It contains, amongst others, figures and descriptions of two kinds of vertical boring machines, of three kinds of horizontal boring machines, of a machine for turning the trunions, of two different machines for boring the touch-hole, of a machine for putting copper boshes in brass guns, and of various instruments for examining and proving guns.

Before the gun is sent off, it is examined and proved in various ways. And first, to ascertain whether the bore is free from holes, an instrument is employed, consisting of several elastic steel prongs disposed in a circle, and with their sharp points turned outwards. This being fixed on a pole, is introduced into the bore of the gun, and drawn to and fro; the points of the prongs press against the sides of the bore, and the presence of a hole is known by one of the prongs getting into the hole, and preventing the instrument from being drawn out directly, unless by the use of a ring that is pushed over the prongs to unbend them.

There is another instrument, composed of a board twice as long as the bore of the piece. Along the middle of the board is a groove proceeding in a straight line. In this groove a button is movable, and on the button, as a centre, are fixed two radii or arms; the two ends of these arms within the gun describe a line on the inside of the bore when the button is pushed inwards, whilst the extremities of the

Boring.

Boring. arms on the outside describe two similar lines on the part of the board that is situate without the bore. In this way the outline of a longitudinal section of the bore is described, and its sinuosities or deviation from the axis are rendered sensible. This instrument is seldom used; it requires to be made by a workman skilled in the construction of mathematical instruments, or in watchmaking.

A lighted wax-candle is introduced into the gun for the purpose of seeing any defects there may be in the bore, or the light of the sun is reflected into the bore by a mirror. The strength of the gun is proved by firing it with a large charge of powder; and by forcing water into the bore by a powerful forcing pump, the touch-hole being stopped, and also the mouth of the piece, so that water forced in by the mouth cannot return that way.

Cylinders. 2. BORING OF CYLINDERS for steam-engines, and for blowing machines, and the boring of the working barrels of large pumps, and other hollow cylinders in which pistons are to work, is performed by making the steel-cutters describe a cylindrical surface on the inside of the cylinder, whilst the cylinder remains fixed. The first steam-engine cylinders in this country were of brass, or of a mixture of copper and tin. This was the case with the cylinder of the steam-engine erected in the early part of the eighteenth century for lifting water from the colliery of Elphinston in Stirlingshire. But since that period the construction of steam-engines, and the manufacture of cast-iron, have been greatly improved; the uses of both have been much extended; and cast-iron has now for a long time been the only material employed in making cylinders for steam-engines, and other large cylinders in which pistons are to move.

In the boring of cylinders the steel-cutters are fixed in a cutter-head, which revolves with the boring-bar at the same time that it is impelled along the interior surface of the cylinder by a rack, with a pinion moved by a lever and weight as already described. The axis or boring-bar employed for cylinders is a hollow tube of cast-iron, and has a groove passing through it; the length of this groove being proportioned to the length of the cylinder to be bored. The cutter-head consists of two cast-iron rings, the first of which is accurately fitted on the boring-bar, which is turned truly cylindrical, so that this ring may slide along the boring-bar; the second ring is fixed round the first by wedges, its diameter being proportioned to the diameter of the cylinder to be bored; and on its circumference are eight notches to receive the steel-cutters, which are fixed in by wedges. The first ring is fixed on the boring-bar so as to make the whole cutter-head move round with the boring-bar, by means of two small iron bars, which go through notches in the first ring, and pass through the groove of the boring-bar. These small bars have each a round hole in the part which passes through the geometrical axis of the boring-bar; through these round holes there passes a bolt, which forms the end of the rack; a key is put through the end of the bolt, which prevents the rack from being drawn back by the lever and weight; and by this means the rack, impelled by the lever and weight, pushes forward the cutter-head, which is at the same time revolving with the boring-bar; while the connection of the rack and cutter-head being round, and in the axis of motion, the rack is thereby free from the circular motion of the cutter-head. This mode of constructing the boring-bar was invented in the works of Mr Wilkinson, at the time when accurately-bored cylinders came to be required in consequence of Mr Watt's improvements in the steam-engine. In the machines about to be mentioned the cutters are made to advance by a train of wheels deriving their motion from the power that turns the boring-bar.

An apparatus of great merit was contrived and describ-

ed in 1802 by Mr Billingsley, engineer of the Bowling iron-works, near Bradford. (See *Repertory of Arts*, second series, vol. ii. p. 322.) According to his method the cylinder is placed with its axis perpendicular to the horizon. The object of this is, *first*, that the boring-dust may fall out, and not remain on one side of the cylinder, wearing the cutters; so that in this way the cylinder may be bored through without changing the cutters, by which means a more regular bore is obtained. *Secondly*, That the cylinder may not deviate from its cylindrical form by its own weight, a deviation which is found to take place in large and slender cylinders when laid on their side; the vertical diameter being then less than the horizontal diameter. A similar loss of shape may happen to cylinders that are improperly wedged and strapped down for the purpose of being bored. In this method the cylinder is fixed with screws by the flanges, where it is most capable of resistance, and the screws are disposed so as to press the cylinder equally all round. *Thirdly*, That the operation may be sooner completed, which is effected in consequence of less time being employed to fix the cylinder in this method. In the usual mode of propelling the cutters described above, the attendance of a man is necessary to change the position of the bar on the axis of the pinion, and to raise the weight. This attendance is dispensed with in the machine under consideration, the mechanism for propelling the cutters being as follows: A leather strap passing over the boring-bar communicates the revolving motion of the boring-bar to a wheel, which communicates a slow motion by a train of wheels and pinions to an axis, bearing two pinions which work into two racks; and these racks push the boring-head and cutters slowly forward on the boring-bar, at the same time that the boring-head is revolving with the boring-bar. The velocity with which it is required that the cutters shall advance varies as the diameter of the cylinder varies, the moving power remaining the same. And by altering the train of wheel-work, the cutters may be made to advance with any velocity required.

Figs. 1, 2, 3, and 4, Plate CXI., are different views Murray's of the machine for boring cylinders, invented by Mr Murray of Leeds. Fig. 1 is an elevation, and fig. 2 a plan, of the machine. W, figs. 1 and 2, is the spur wheel, deriving its motion from water or steam, and communicating a revolving motion to the boring-bar. The toothed wheel A, fig. 1, moves round with the boring-bar B on which it is fixed; it gives motion through the wheels D and E, and to the screw S, whose threads act on the two racks, which racks are fixed to the cutter-head H, and revolve with it. The velocity with which the cutter-head is impelled along the cylinder depends upon the number of threads of the screw in a given length, and on the proportions of the wheels A, C, D, and E, to each other. By varying the velocity of the screw, the cutter-head may be made to move in either direction up or down the cylinder. F is a pinion whose axis ends in a square, which may be wrought by a key, so as to bring the cutter-head out of the cylinder, or push it home by the hand when that is required. The cylinder is fixed in its bed by screws passing through two iron rings, as represented at fig. 4; and in this way the cylinder is equally pressed in the different parts of its circumference. Fig. 3 is a transverse elevation of the collar in which the end of the bar at A, fig. 1, turns; X is the gudgeon in which the spindle X, fig. 1, turns. In fig. 3 are also seen the two apertures through which the two racks pass. By this machine also the flanges are turned truly plane, so that the lid of the cylinder may fit on exactly.

The patent granted in 1799 to Mr Murdoch, engineer, Redruth, for new methods of constructing steam-engines

Boring.
Billingsley's machine.

Boring. (See *Repertory of Arts*, vol. xiii.), contains some articles relative to boring. He employs an endless screw, which is turned by the moving power, and works into a toothed wheel, whose axis carries the cutter-head; and this method, he says, produces a more smooth and steady motion than the usual mode of fixing the boring-bar immediately on the axis turned by the moving power.

Murdoch's patent. Another article in Mr Murdoch's patent that relates to boring, is his method of forming the cylinder and steam-case. He casts them of one solid piece, and then bores a cylindrical interstice, by means of a boring-tool, made of a hollow cylinder of iron, with steel-cutters fixed to its edge, and acting like a trepan.

The chambers of brass pumps, whose diameter does not exceed a few inches, are fixed within iron rings, by means of screws, in the manner described above when speaking of Mr Murray's apparatus. The rings are made accurately cylindrical by turning, as is also the boring-bar. The boring-bar has four cross arms on its outer extremity, to one of which a handle is fixed, whereby a workman makes the boring-bar revolve. The cutter-head is made to advance along the boring-bar by a screw.

Muskets. 3. BORING THE BARRELS OF MUSKETS AND OTHER SMALL ARMS. Rectangular pieces of iron are forged of a proper length and breadth; these are heated in the fire, and the two long edges, which had been previously thinned off, are welded together on a mandril. The barrel thus formed is fixed by a screw on a carriage that moves in iron grooves; this carriage is propelled towards the boring-bar by a rope which passes over pulleys, and has a weight hanging from its end. The boring-bar is turned by the power of the same mill that turns the grinding-stones for polishing the outside of the barrels. (See *Encyclopédie—planches, Arquebuser*; and Rozier, *Introduction aux Observations sur la Physique*, tom. i. p. 157.) Water is thrown on the barrels whilst boring from a trough placed underneath. After the barrel is bored, the interior surface of the bore is polished by the action of the boring-bar. The barrel is tried during the operation, by an iron gauge of an inch and a half in length, and of a diameter equal to the intended diameter of the musket. When the barrel is bored, it is held to the light and looked through, and if it contains any flaw, the place of that flaw is marked on the outside with chalk, and the barrel is put on the mandril again, and the defective place heated and hammered; the workman also examines with a gauge whether the barrel is crooked. When the bore has no flaws, the barrel then undergoes the operation of the grinding-mill, to the effect of polishing its exterior surface.

Rifled barrels are put on a bench twelve feet long. The boring-bar is guided by a matrix or female-screw, whose spiral curve is similar to the spiral of the rifles intended to be made; the boring-bar being fixed to a male-screw, which passes through the female-screw, and fits it exactly. The female-screw is fixed to the bench, and has four threads and as many furrows; and these threads, in general, return to the point of the circumference from which they set out, or make a revolution in the length of two feet. The male-screw, which fits into the female-screw, has at one end an iron bar attached to it, by which it is put in motion; at the other extremity is fixed the boring-bar, which passes through the barrel to be rifled; and the boring-bar has a cutter fixed in it, which forms a spiral furrow in the barrel when the screw is turned by the handle. The number of spiral threads in rifle-barrels is from three to twelve. Sometimes the threads and furrows of the rifle-barrel are required to be in straight lines; in which case a straight-lined matrix is used. In order that the threads may be placed at an equal number of degrees of the circumference from each other, the bench is furnished with

a brass plate, divided in the same way as the plate of the machine for cutting the teeth of clock-wheels.

Boring. 4. BORING OF PORTLAND STONE, so as to form pipes. Portland stone. That kind of calcareous stone called by geologists oolite, which is quarried for building at Portland, Bath, in the neighbourhood of the city of Paris, and other places, admits of being cut by means of an iron blade, acting as a saw, with sand and water. The more compact limestones and marbles are also cut in this way, but not so easily. The other kinds of stone that can be squared for building, namely, sandstone and granite, scarcely yield to the saw, but are formed into the desired shape by the chisel and hammer. A modification of this mode of working Portland stone consists in forming it into pipes. The method of Sir George Wright, proposed in 1805, is as follows: A hole is drilled through the block of stone, in which a long iron bolt is inserted for the saw to work round as a centre; this bolt forms the axis of the cylinder which is to be taken out, and projects considerably beyond the block at both ends. Another hole is drilled in the intended circumference; and into this the blade of the saw is introduced. The frame of the saw is so disposed, that when it is wrought to and fro, the blade is guided, by means of the centre bolt, so as to describe the intended cylindrical circumference. In this way a solid cylindrical core of stone is detached, and a cylindrical cavity or pipe left in the block. Or the saw may be made to describe a circle without drilling a hole in the centre, by drilling a hole in the circumference, and fixing on the surface of the stone two metallic concentric rings, so that the hole shall be included in the interstice between the rings. The saw is then introduced into the hole, and being worked, it cuts in the circular path formed by the interstice of the rings. See *Repertory of Arts*, second series, vol. viii.

Mr Murdoch's method, for which he obtained a patent in 1810, is preferable in practice to the above-mentioned method. He employs a cylindrical saw to form the pipe. A plug of wood is inserted in the centre of the intended pipe; this plug receives the lower end of a vertical spindle, longer than the intended pipe; and this spindle is square, with sockets sliding on it. On the upper part of the spindle is a pulley or toothed-wheel, by which the spindle is made to revolve. Near the lower end of the spindle is a wheel, having a circumference like a hoop, three inches broad. The diameter of this wheel is somewhat less than that of the pipe to be bored. It regulates the motion, and fits in the inside of a tube of metal attached to the spindle. The diameter of the tube is nearly equal to that of the intended pipe; but its length is greater by two feet. On the lower edge of the tube is a rim of metal, so much thicker than the tube that the groove cut in the stone by the rim may admit the tube to move freely in it. This rim has an edge like that of a stone-cutter's saw, and in fact performs the office of a saw. The tube is caused to make a reciprocating circular motion round the spindle. There is a cistern placed above the tube, for the purpose of conveying a mixture of sand and water into the cylindrical groove formed in the stone, whilst the machine is working.

Stone pipes, made in the above described way, have been tried for conveying water in London. They were joined by means of Parker's cement, which consists of clay ironstone, burnt, and ground to a fine powder. This was the best material that could be got for forming the joints; but these joints cracked and allowed the water to escape, in consequence of the motion of the carriages on the streets under which the pipes were laid; and the adventurers found that they "had hewed out unto themselves broken cisterns, that could hold no water."

5. BORING OF ROCKS, for the purpose of splitting them by means of gunpowder. We have already treated this sub-

Boring. ject under **BLASTING**, and shall only add here the mode of boring for this purpose practised in the mines of Germany.

A boring bar of steel is applied to the stone by its lower end, whilst its upper extremity is struck with a hammer of two pounds in weight. The form of the lower end of the boring-bar is various; some were fashioned like a swallow's tail, ending in two points; but this form is no longer in use. Another kind has the end formed by the intersection of two wedge-shaped edges, with a point at each corner, and one in the middle. A third kind has the end composed of four pyramidal points, with cavities between them. A fourth kind, which is that most frequently used, has the end in form of a wedge. (See Rinman, *Bergwerks Lexicon*. Stockholm, 1789, tab. ii.) Three sizes of boring bars are employed to make one hole, the first is the shortest and thickest, the second is longer and less in diameter, the third is the longest and the least in diameter. When a hole is to be made, a small opening is first formed with a pick in the place where the boring-iron is to be applied, and all pieces of the rock are removed that might impede the action of the powder. Then the workman uses the first boring-iron, which he drives with blows of the hammer till the boring-iron can reach no farther; he then employs the second and third boring-bars in like manner; and after each stroke of the hammer, the boring-bar is turned round a portion of the circumference. The stone, pulverized by the action of the boring-bar, as it hinders the progress of the operation, must be removed from time to time by means of an iron-rod, terminated at right angles by a small round plate. From the different diameter of the boring-bars, it follows that the end of the hole is of a smaller diameter than that of the beginning. The depth to which the hole is bored is proportioned to the nature of the rock. It varies from 10 to 15 and 20 inches. When the rock is solid a great way round, a deep hole is not used, because the resistance at a considerable depth, in such a situation, is too great; so that the explosion does not split the rock round the powder chamber, but acts upwards against the ramming, where it meets with less resistance. But if the rock be laid bare on one side, a deep hole is advantageous. Water is poured into the hole during the operation, to facilitate the action of the boring-iron. When the hole is perpendicularly downwards, it is kept full of water; when the hole is driven from below upwards, no water can be used. The water must be taken out, and the hole dried, before the cartridge be introduced. The most frequent case is, that one man performs the work, holding the boring-iron in his left hand, and striking on it with the two-pound hammer in his right. Sometimes two men are set to do the work, one holding the boring-iron, whilst the second strikes it with a hammer of four or five pounds: this is done where it is required to make the hole thirty or thirty-six inches deep. When a still deeper hole is wanted, two men strike alternately with heavier hammers.

Wooden pipes.

6. **BORING OF WOODEN PIPES** is done by means of a long auger, beginning with one of small diameter, and proceeding to employ successively spoon-formed augers of larger diameter. Notwithstanding the frequent employment of cast-iron pipes, some wooden pipes are still used for conveying water in London: they are of elm, which is the kind of tree most frequent in the neighbouring country. A pipe is bored out of one trunk of elm, and the bark is left on. When a tree is to be bored, it is fixed on a carriage, with a rack on the under part. This rack fits into a pinion, the axis of which passes through gudgeons on a fixed frame. On the axis of the pinion is a ratchet wheel, moved by two catches, which derive their motion from the wind or water power that turns the auger; and the pinion is moved in a direction that brings the tree towards

the auger. See a figure in Belidor, *Architecture Hydraulique*, i. 1, 341. This apparatus is the same as the one employed in saw-mills. In the boring of pipes for the water-works in London, the tree is made to advance by ropes, which pass over a windlass wrought by men, whilst the auger is turned by a horse-mill. Wooden pipes are frequently bored by an auger having at its outer end a wooden drift or handle, which is put in motion by the workman. The trees are placed on tressels, and there are also tressels of a convenient height that support the auger; there is also a lathe to turn one end of the tree conical, so as to fit into a conical cavity in the end of the adjoining tree, and thus form a water-tight joint. The end of the tree which receives the adjoining pipe within it has a surface at right angles to the axis of the pipe. Into this surface is driven an iron hoop, the diameter of which is some inches greater than the diameter of the aperture of the pipe. This precaution prevents the tree from splitting when the conical end of the next tree is driven home. When the tree is crooked, a bore is driven in from each end, and the two bores meet, forming an angle. An auger whose stalk is formed spirally for some way up is figured in Bailey's *Machines of the Society of Arts*. The objects of this is that the chips may be delivered without taking the auger out of the hole.

There is a patent granted in 1796 to Mr Howell, coal-master, of Oswestry, for boring wooden pipes by a hollow cylinder made of thin plates of iron, about an inch less in diameter than the hole to be bored. To one end of this cylinder is fixed a flange about a quarter of an inch in breadth, and one part of this flange is divided, so that, being of steel, a cutter is formed thereby. The object of this method is to bore out a solid cylinder of wood, capable of being converted into a smaller pipe, or of being applied to some other use in carpentry. (*Repertory of Arts*, vol. ix.) This kind of borer is like the trepan, which is a hollow cylinder of steel, saw-toothed on the edge, and, when made to revolve rapidly on its axis in the hand of the surgeon, it saws or bores out circular pieces of the flat bones of the head. (B. B.)

BORISSOGLEBSK, a circle of the Russian government of Tambow, extending over 2412 square miles, with a population of 65,400 persons. The chief place, a city of the same name, on the river Khoper, contains about 500 houses and 3300 souls. Long. 42. 1. E. Lat. 51. 23. N.

BORISTHENES, or **BORYSTHENES**, in *Ancient Geography*, the largest river of Sarmatia Europæa, and described by Mela, after Herodotus, as running through a cognominal people; as the pleasantest of all the rivers in Scythia, calmer than any of them in its course, and very agreeable to drink; as producing rich pastures, and large fish, of the best flavour, without bones; as flowing a great distance, and rising from springs unknown; and as being navigable for a course of about forty days. It is now called the *Dnieper* or *Nieper*.

BORKEN, a circle in the Prussian government of Munster, and province of the Rhine. It is on the frontiers of the kingdom of the Netherlands, and extends over 307 square miles, or 196,480 acres. It contains four small cities, nine villages, and forty-four hamlets, with 5703 houses and 36,170 inhabitants. It is an undulating but heathy and moorish district, yielding chiefly buck-wheat and flax. Some little iron, much wood, and some coarse wool, are the chief productions. The capital, of the same name, situated on the river Aa, contains 450 houses and 2437 inhabitants. The whole district belonged formerly to the family of Solm Solm, now mediatised.

BORKUM, an island of Hanover, on the coast of East Friesland, situated between the mouths of the East and West Ems, and included in the bailiwick of Grutsiel. It

Boring
||
Borkum.

Borlase. is about twelve miles in circumference, and so low in the middle that it is separated into two parts at high water. A considerable proportion of the inhabitants consists of seafaring people, and the remainder draw their support from the rearing of cattle, or in picking up the fragments of vessels wrecked on their coast. It has a governor, a minister of the Calvinistic faith, and a schoolmaster.

BORLASE, DR EDMUND, an eminent physician and English writer in the seventeenth century, was the son of Sir John Borlase, master of the ordnance, and one of the lords justices of Ireland in 1643. He studied in Dublin College, and afterwards at the university of Leyden, where he took the degree of doctor of physic. He afterwards practised physic with success in the city of Chester, and was incorporated doctor of the faculty in the university of Oxford. Among the books which he wrote and published are the following: 1. Latham Spaw in Lancashire, with some remarkable cases and cures performed by it, London, 1670, 8vo; 2. The Reduction of Ireland to the crown of England, London, 1675, 8vo; 3. The History of the Irish rebellion, London, 1680, 8vo; 4. Brief Reflections on the Earl of Castlehaven's Memoirs, relative to the part which he took in the Irish War, London, 1682, folio. The precise time of his death is uncertain.

BORLASE, William, a learned antiquary and naturalist, was descended of an ancient family in Cornwall, and born at Pendeen, in the parish of St Just, on the 2d February 1695-6. He was put early to school at Penzance, and in 1709 removed to Plymouth. In March 1713 he was entered of Exeter College, Oxford; and in June 1719 he took his degree as master of arts. In 1720 he was ordained as priest, and in 1722 instituted to the rectory of Ludgvan in Cornwall. In 1732 Lord Chancellor King presented him to the vicarage of St Just, his native parish; and this, with the rectory already mentioned, were all the preferments he ever obtained. In the parish of Ludgvan are rich copper works, abounding with mineral and metallic fossils, which, being a man of an active and inquisitive turn of mind, he collected from time to time, and thus was led to study at large the natural history of his native county. He was also much struck with the numerous monuments of remote antiquity that are to be met with in Cornwall; and therefore, enlarging his plan, he determined to gain as accurate an acquaintance as possible with the learning of the Druids, and with the religion and customs of the ancient Britons before their conversion to Christianity. In 1750 he was admitted a fellow of the Royal Society; and in 1753 he published in folio, at Oxford, his "Antiquities of Cornwall," a second edition of which was published, in the same form, at London, 1769, with the title of "Antiquities, Historical and Monumental, of the County of Cornwall; consisting of several essays on the ancient inhabitants, Druid superstition, customs and remains of the most remote antiquity in Britain and the British isles, exemplified and proved by monuments now extant in Cornwall and the Scilly islands; with a vocabulary of the Cornu-British language." His next publication was "Observations on the ancient and present state of the islands of Scilly, and their importance to the trade of Great Britain." Oxford, 1756, 4to. This was merely an extension of a paper which had been read to the Royal Society in 1753. In 1758 appeared his "Natural History of Cornwall," Oxford, folio. After these publications, he transmitted a variety of fossils and remains of antiquity which he had described in his works, to be deposited in the Ashmolean Museum; for which, as well as other benefactions of a similar kind, he received the thanks of the university, in a letter from the vice-chancellor, dated the 18th November 1758; and in March 1766 the degree of doctor of laws was conferred on him. He died

in 1772, at the age of seventy-seven, leaving two sons out of six, whom he had had by a lady he had married in 1724. Besides his literary connections with many ingenious and learned men, he had a particular correspondence with Mr Pope; and there is still extant a large collection of letters written by that poet to Dr Borlase. He furnished Pope with many of the materials, consisting of curious fossils, which formed his grotto at Twickenham; and Dr Borlase's name in capitals, composed of crystals, might be seen in the grotto. It is with reference to this circumstance that Pope says in a letter to Borlase, "I am much obliged to you for your valuable collection of Cornish diamonds; I have placed them where they may best represent yourself, *in a shade, but shining.*" Besides the works above mentioned, he sent many curious papers to the Philosophical Transactions, and had in contemplation several other works.

BORMIO, a town of the Austrian kingdom of Lombardy, in the delegation of Como. It is situated at the foot of a lofty hill of the same name, is well built, and contains about 2000 inhabitants. Long. 9. 51. E. Lat. 46. 28. N.

BORN, IGNATIUS, BARON VON, counsellor in the aulic chamber of the mint and mines at Vienna; of considerable eminence in the scientific world as a mineralogist and metallurgist, and a promoter of science; was born of a family that had the rank of nobility, at Karlsburg, in Transylvania, in 1742; and died in 1791. He was educated in a college of the Jesuits at Vienna, and afterwards entered into that order, but continued a member only during sixteen months. He then went through a course of study in law at Prague, and afterwards travelled into Germany, Holland, and France. On his return to Prague he engaged in the study of mineralogy.

The mines in the dominions of the house of Austria are very important, and give livelihood to a numerous population, more particularly in Hungary, Transylvania, and the Bannat, and in Styria and Carinthia. Idria produces mercury; Bohemia, tin and cobalt; and the other metals are obtained in sufficient abundance, not only to supply the internal trade of the nation, but also for export, either in the form of raw metal, or manufactured into various instruments. A revenue accrues to the public treasury from the mines in various ways. Some, as those of Schemnitz, Cremnitz, and Idria, are wrought on account of government. A tenth part of the produce of all mines wrought by private adventurers goes to government as a royalty. Government has a right of pre-emption of all metals, and an exclusive right of buying all gold and silver, the produce of the country, at a stated price. The annual quantity of gold and silver got from the mines of Hungary and Transylvania, and coined into money at the mint, during the reign of Maria Theresa, amounted in value to about L.300,000 sterling. The mines in other parts of the dominions produced likewise a considerable quantity. Maria Theresa, seeing their importance, did much for the regulation of the mines; and, with a view of diffusing the knowledge of mineralogy amongst the nobles, many of whom were proprietors of mines, she had lectures on that science delivered in the universities. The administration of the revenue arising to government from this source is conducted by a board composed of managers, overseers, assayers, and other officers, who are brought up in the knowledge of metallurgy and mineralogy, and reside at the mines. The operations of these functionaries are under the control of the aulic chamber of the mint and mines at Vienna, which keeps a set of books, in which all the transactions relative to the mines, and their situation and state, are digested and registered. An administration thus constituted offers a field of some preferment. Von

Bormio

Born.

Born.

Born chose to devote himself to this line of life, and was received into the department of the mines and mint at Prague in 1770.

About this time he met with an accident which nearly proved fatal. In the course of a mineralogical journey through Transylvania, he came to Felso-Banya, where the gang is rendered brittle and detached from the rock, by exposing it to the flames of wood heaped up in the mine and set on fire. Having gone into the mine soon after the combustion had ceased, and whilst the air was hot, and charged with arsenical vapour, and returning through a shaft which was occupied by a current of this vapour, he was deprived of sensation for fifteen hours, and after recovery continued long to suffer from a cough and general pain. Some time after this accident he was affected with violent colics, which a large dose of opium removed, but left him with a numbness of the lower extremities, and lameness in the right leg. In the latter part of his life he was deprived of the use of his legs. All these calamities, which, however distressing, did not repress the activity of his mind, were considered as the consequences of the arsenical fumes he had inhaled at Felso-Banya.

One of the chief objects of his exertion was to introduce amalgamation in Hungary, in place of smelting and cupellation heretofore used in that country, for extracting silver from the ores. Pliny and Vitruvius speak of the use of mercury in collecting small disseminated particles of gold. On the arrival of the Spaniards in America, the Peruvians extracted the silver from the ore by smelting-furnaces, exposed to the wind on the tops of hills. The quicksilver mines of Guancabellica in Peru were discovered in 1563, and three years thereafter the Spaniards began to employ amalgamation. Alonzo Barba, an Andalusian, further improved the process by the addition of heat. Amalgamation had been practised in Europe for collecting silver and gold when they existed in visible metallic particles, but not in the case of ores where the gold and silver are invisible even with the aid of a microscope. Soon after its application to ores in America, an attempt was made by a Spaniard to introduce this operation for extracting silver from the ores in Bohemia, but without success. Gellert, Walerius, and Cramer, had written against the use of amalgamation when applied to ores. But Von Born seeing its advantages, particularly in the saving of fire-wood, which had become scarce in many parts of Hungary, set about examining the accounts given by authors of the different processes used in Mexico and Peru; repeated these processes experimentally, first in the small way, leaving out the ingredients that a knowledge of the chemical action of bodies showed to be unnecessary; and afterwards had the process carried on in the great way for several months near Schemnitz, under the inspection of Ruprecht. At this time he published his book *On Amalgamation*. It contains a history of amalgamation, and extracts from different authors describing the South American methods. This occupies nearly one half of the volume. He then gives the chemical theory of operation in its different steps, describes the method he had adopted at Schemnitz, and gives figures of the machinery employed.

Von Born met with much opposition in his attempts to introduce amalgamation. He says that some book-learned chemists, who never had handled a retort, and some mine overseers, when he first set about his experiments, declared that it was impossible to obtain silver by that method. After he had succeeded in getting silver from the ore publicly at Vienna, his detractors came forward with doubts and long calculations, showing that the process was inferior to that already in use. At last his process was tried successfully in the great way by orders of

Joseph II. at Schemnitz; and then the calculators and doubters shrugged up their shoulders, saying, "It is only the old Spanish process of amalgamation." Born.

He obtained from the emperor an order that his method should be employed in some of the mines belonging to government, and that he should receive a third part of the savings arising from the improvement during the first ten years, and four per cent. of this third part of the savings for the next twenty years.

He was a satirist, without possessing the qualities of style that are necessary to attain a high rank in that class of writers. The *Staats Peruche*, a tale, published without his knowledge in 1772, and an attack on Father Hell, the Jesuit, and king's astronomer at Vienna, are two of his satirical works. The satirical description of the *Monastic Orders*, written in form of an academic inaugural dissertation, entitled *Monachologia*, is generally ascribed to Von Born. In this piece the monks are described in the technical language of natural history. Von Born, however, was not deeply versed in the phraseology of Linnæus; and it is the opinion of some good judges of the subject, that the language at least was furnished by Herman, professor of medicine in the University of Strasburg, and author of the very ingenious work on the mutual affinities of animated beings, entitled *Tabula Affinitatum Animalium Commentario illustrata*. But although the technical language may not be Von Born's, the sentiments are such as he was known to profess; for the topic was so great a favourite with him, that he found room for invectives against the monks even in his book *On Amalgamation*. The monks in the Austrian dominions were not then in a situation to obtain redress against this lampoon; for it was published in 1783, when Joseph II. had suppressed many of the monasteries in different parts of his dominions, and transferred their property into his treasury, allowing but a scanty sum for the subsistence of the members of these communities.

Von Born was well acquainted with Latin, and the principal modern languages of Europe. He also possessed information in many branches of science not immediately connected with metallurgy and mineralogy, which were his professed pursuits. He had a good taste in the graphic arts, and his printed works are ornamented in a neat manner with vignettes illustrative of the subject.

His inclination led him to engage in politics; and, in particular, he took an active part in the political changes in Hungary. After the death of Joseph, the diet of the states of Hungary passed a great many acts, rescinding the innovations of that scheming ruler, which tended to force upon them German governors and laws, and even the German language. This diet conferred the rights of denizen on several persons of distinction who had been favourable to the cause of the Hungarians, and, amongst others, on Von Born. At the time of his death he was employed in writing an historical work in Latin, entitled *Fasti Leopoldini*, probably relating to the prudent conduct of Leopold II., the successor of Joseph, towards the Hungarians.

He was of a middle size, slender make, and dark complexion; his eye was penetrating, and his countenance agreeable. His constitution was delicate even before his accident. He was a pleasant companion, and fond of society. He lived in splendour, and his house at Vienna was resorted to by scientific men of all nations. It is likely that his profits from the process of amalgamation were not considerable, at least they were not sufficient to put his fortune to rights, as his affairs at his death were in a state of insolvency. His family consisted of a wife and two daughters, who survived him. (See Townson's *Travels in Hungary*; and Pezzil, *Ostreich Biographien*, 1792.)

Born.

The following is a list of his published writings, and of the works of others which he edited.

Lythophilacium Borneanum, 1775, 8vo. This is a catalogue of his collection of minerals, which collection he afterwards sold to Mr Greville; and it forms a part of the magnificent Greville collection of minerals purchased from the heirs of that gentleman by parliament, and deposited in the British Museum. This catalogue is arranged according to the system of Cronstedt, with the nomenclature of Linnæus.

Index rerum naturalium Musæi Cæsarei Vindobonensis. Pars. I. Testacea. Vindob. 1778, fol. maj. This splendid volume, which contains the description and figures of the shells in the museum at Vienna, was composed by order of the Empress Maria Theresa. The shells are arranged according to the method of Linnæus. Von Born's knowledge in this department of Natural History was not profound, so that he needed some assistance in composing the work. The shells only are described; of the animals to which they belong little is said. Joseph II. coming to the throne, and being fully occupied with a multitude of innovations and vast schemes for the aggrandisement of the house of Austria, the project of continuing the work, so as to form a description of the whole museum, was laid aside.

On the Amalgamation of Ores containing Gold and Silver, in the German language, published in 4to in 1786. Of this work something has been already said above. There is a translation of the work into English, by Raspe, a Hanoverian, once professor at Hesse-Cassel, and who afterwards resided in Britain, where he was sometimes employed as a viewer of mines.

Catalogue méthodique et raisonné de la Collection des Fossiles de Mademoiselle Eleonore de Raab, à Vienne, 8vo, 1790. This catalogue is drawn up so as to form a system of mineralogy, each species of mineral being carefully described, and arranged systematically. It was much esteemed, and cited by mineralogical writers in its time, but has been superseded, like other treatises, by more recent works, on account of the great additions that have been continually making to the science.

He edited the Jesuit Poda's description of the machines used in the mines of Schemnitz.

Ferber's Letters from Italy were written to and edited by Von Born. Ferber and he were in habits of great intimacy; and Ferber, in return, published the letters that Von Born addressed to him during his excursion in Transylvania, &c. in 1770, entitled *Briefe über mineralogische gegenstände auf seiner reise durch das Temeswarer Bannat, Siebenburgen, Ober und Nieder Hungarn*. Frankf. 1774. To this work is prefixed a well-engraved portrait of Von Born. There is an English version by Raspe, and a French one, with notes, by Monnet.

He lent his assistance to the first three volumes of a work published in German, entitled *Portraits of Learned Men and Artists, natives of Bohemia and Moravia*.

There are some papers of his in the *Abhandlungen der Böhmischer gesellschaft den Wissenschaften*.

The Transactions of a Private Society at Prague, in Bohemia, for the improvement of mathematics, natural history, and the civil history of the country, contains several papers written by him. He was the founder of this society.

He published an annual periodical work in German, entitled the *Philosophical Transactions of the Masons' Lodge of Concord at Vienna*. This masons' lodge, of which Von Born was the founder and patron, employed a part of its meetings in scientific pursuits. This, as well as other societies of a similar nature, was tolerated by Joseph II. for some time; but he afterwards imposed restraints that

VOL. V.

caused their dissolution. Von Born was also a zealous member of the Society of Illuminati; and when the Elector Palatine of Bavaria suppressed the masonic societies in his dominions, Von Born being a member of the Academy of Sciences at Munich, was required to declare, within eight days, whether he would withdraw from the masonic societies. He returned an answer, in which he praised the principles of the free-masons, and resigned his place in the academy, by sending back his diploma.

He wrote some articles in the German work published by Trebra, mine-director at Zellerfeld in the Hartz, entitled a *System of Instruction in the Art of Working Mines*, 4to; also *Observations in support of the Metallization of the Alkalis*, in Crell's *Annals*, 1790, 1791. Ruprecht and Tondi thought at that time that they had reduced the alkalis and barytes to a metallic state, by the strong heat of a furnace urged by bellows; but it was afterwards found that the metallic substance thus obtained was phosphate of iron, proceeding from their crucibles and fluxes. Sir Humphry Davy was the first who obtained any of the alkaline class of bodies in a metallic state; and this he accomplished by the intense heat excited by a galvanic battery, many years after the time here spoken of.

Relatio de Aurilegio Daciæ Transalpinæ, 1789, in the *Nova Acta Academiæ Naturæ Curiosorum*, tom. viii. p. 97. This is an account of the method employed in Transylvania in collecting gold from the sand of the rivers. The auriferous sand generally contains iron, attractable by the magnet. It is washed on a sloping board seven feet long and three feet broad, covered with a woollen cloth, having a dish-shaped cavity at the upper end, and inclined to the horizontal plane at an angle of twenty or twenty-five degrees. Only a very scanty livelihood can be gained by this employment. It is carried on by the poorer classes of the country people, and in some districts by bands of the people called gipsies. The king's collectors buy the gold from the gold-washers at a stated price, to the amount of more than 800 pounds weight annually. (B.B.)

BORNEO, an island forming part of the great East Indian Archipelago. Next to New Holland, which may be considered as a species of continent, it seems indisputably the largest in the known world. It reaches from about 7° north to 4° south latitude, and from 109° to 118° east longitude. Its length may be estimated at 750 miles, its greatest breadth at 600, and its average breadth at 350. It exhibits the usual insular structure, a mass of lofty mountains in the centre, sloping gradually down to level and alluvial tracts along the sea shore. It is watered by many fine rivers, of which those of Borneo Proper, Banjar Massin, and Passir, are navigable for more than fifty miles above their junction with the sea. All these rivers were understood by Dr Leyden to be derived from an immense lake in the interior, called the Sea of Manilla. It is more probable that they all rise from the mountainous district of greatest elevation. The interior of Borneo is covered with immense forests, filled with wild animals, particularly ourang-outangs. A great part of the coast is marshy, so that it is in portions only that it displays the exuberance of tropical fertility. Of all the East Indian islands, Borneo ranks lowest as to civilization and improvement. Nothing, perhaps, has tended so powerfully to check its progress as the solid and unbroken form of its coasts, destitute of those large bays or inland seas which have always proved the nursery of commerce.

The Portuguese discovered Borneo in 1526, though, from the superior wealth promised by the Spice Islands, it attracted comparatively little attention. Yet they, as well as the Spaniards, the Dutch, and the English, formed establishments on different parts of the coast; but the small force defending them, and the fierce animosity of the na-

Born
||
Borneo.

Borneo. tives, made their tenure generally of very short duration. The physical structure of Borneo, the vast forests, mountains, and jungles of the interior, obstruct communication between the different parts of its coast, as completely as if an extent of sea had intervened. It is thus split into a number of petty districts, entirely detached from each other, and which cannot be satisfactorily described, unless in detail. In this manner, therefore, we shall consider the principal states, beginning with Borneo Proper, and thence making the circuit of the island; after which we shall attempt some general views of its population and commerce.

Borneo Proper occupies the northern coast, and is reckoned a state of great antiquity. The soil is comparatively fertile, supplying rice sufficient for the consumption of the inhabitants, as well as most of the camphire for which the island is celebrated. The city, called also Borneo, is built upon alluvial ground, about ten miles above the mouth of the river of the same name. It is compared to Venice; canals are conducted through every street, and all business is conducted in boats, usually rowed by women. The houses are built upon posts, and ascended to by ladders. The river is navigable for large vessels considerably above the town; but there is a bar at its entrance, over which there is scarcely a depth of seventeen feet at high water. The sultan is treated with those marks of peculiar respect which in this part of the world usually indicate an ancient dynasty; but the chief power rests in the council of the nobles. This state has little communication with Europeans; and the English, who were accustomed to deal to a small extent in piece-goods, have in a great measure discontinued the traffic. The commerce of this city and district is almost entirely engrossed by the Chinese, who bring annually from Amou four or five junks, of about 500 tons burden. As the neighbourhood abounds in excellent timber, they frequently build their junks here, and carry them away loaded with the commodities of the country.

On the eastern coast of Borneo, Mangedava and Pappal are populous, fertile, and well-watered districts. Malloodo possesses these advantages in a still superior degree, and grows also a large quantity of rattans. Tiroom produces sago in abundance, and birds' nests more copiously than any other part of the eastern Archipelago. None of these states, however, are much frequented by or known to Europeans. The chief state on the eastern coast is Passir, situated about fifty miles up a river of the same name. This district is very low and flat; and, were it not cooled by the sea breezes, would be intensely hot. Being marshy and filled with woods, it is extremely unhealthy. The town is said not to contain above 300 wooden houses, which are built along the river. The sultan has a palace and wooden fort along the northern bank. The people of Passir have an extremely bad reputation as to their conduct in mercantile transactions. They use false weights and measures, manufacture counterfeit articles, and embrace, in short, every opportunity of cheating that offers. The English East India Company made an attempt, in 1772, to establish a factory here, but it did not succeed.

Banjar Massin is the principal state on the southern coast of Borneo; and, like the others, it owes its prosperity to a large river, on the banks of which it is situated. This river is five or six fathoms deep; but, unfortunately, the bar does not allow above twelve or thirteen feet of water, and requires the aid of the tide to produce even that depth. Ships, however, may anchor in the port of Tombangou or Tombornio, near the mouth of the river, where they are well supplied with water and provisions. Banjar Massin, in 1780, was estimated to contain a population of 8500 Mahomedans, chiefly Javanese, with a considerable proportion of Bugis, Macassars, and Malays. The

Chinese are also pretty numerous. The sultan resides at Martapura, about three days' journey up the river, to which place he is attached by the circumstance of its being an uncommonly fine hunting station. The district of Banjar produces gold and diamonds, both of superior quality to those found in other parts of the island. Pepper is so abundant that, in a commercial view, it may be considered as the staple commodity. The iron is very excellent, and peculiarly fit for steel; though Dr Leyden asserts that the inhabitants do not themselves understand the art of manufacturing it. In 1700 the English East India Company formed a settlement at Banjar Massin. A rage then prevailed for multiplying establishments, and the present one was soon so far extended as to equal that of Calcutta. But the expectations of extensive trade, which prompted to such an enlargement, were in a great measure illusory; a thousand tons of pepper being the most valuable article drawn from the settlement. Before the company could be fully aware of its unproductive nature, however, this settlement was brought to a premature end. An attack was made by the natives on so great a scale, and with such fury, that, though repulsed, it seemed to leave no choice but the immediate evacuation of the factory, without even removing the stores. The damage sustained on the occasion is estimated at 50,000 dollars.

Succadana, or, as Dr Leyden calls it, Sacadina, was anciently the most powerful state on the western coast of Borneo. The Dutch began to trade there in 1604, but they soon afterwards attached themselves, in preference, to Sambas. In 1623 they abandoned their factory at Succadana. In 1786 they united with the sultan of Pontiana in an expedition against this place, which they took and entirely destroyed. It appears to have been since rebuilt, but is entirely in the hands of the Malays, and scarcely ever visited by Europeans. Pontiana is a state of very recent origin, but it now exceeds in wealth and power all others upon the western coast of Borneo. This distinction it owes to the wisdom of the Arab prince by whom it was founded. He renounced from the first the pernicious policy, almost universal in these petty states, of embarking in trade, and monopolizing its principal articles. He confined himself to his proper functions, of dispensing justice, and securing protection to all, of whatever country or religion, who resorted to his dominions. Under this salutary policy Pontiana soon rose to be the greatest emporium in those seas. It is situated on a large river, formerly called Laua, and the country behind produces diamonds the most abundantly of any district in Borneo. The Dutch established a factory here in 1776, and maintained ever after a good understanding with the sultan. In 1813, after the British force had taken possession of Batavia, that prince, dreading an attack from Sambas, solicited the protection of a British garrison, which was immediately sent; and he afterwards assisted our troops in the reduction of Sambas. Momparwa, situated a little to the north of Pontiana, is the best market for opium upon this coast. The city lies nineteen miles up the river, the entrance of which is obstructed by a bar and by several small islands. This is probably the same district called Mattan by Dr Leyden, who says that the king possesses the finest diamond in the world, for which a high price was offered by the Dutch, which he refused to accept. Sambas is situated about thirty miles up the river of the same name. Like most other towns in Borneo, it is built of timber and bamboos, and raised by stakes above the swampy foundation. Sambas has always been a powerful state, but for some time past has devoted itself so entirely to piracy as to render its existence scarcely compatible with that of its civilized neighbours. Upon this principle the British, in 1812, undertook an expedition against it;

Borneo. but they were repulsed with great loss in the attack, and suffered still more from the malignant influence of the climate. In the following year, however, a new expedition was undertaken under Colonel Watson, who, on the 3d of July, carried the fort by storm, and obliged the rajah to retire into the interior of his dominions.

On a general view of the state of culture and civilization in Borneo, Mr Hamilton estimates the population at 3,000,000, which we should suppose to be, rather above than under the truth. The interior is entirely occupied by a native race, called variously, according to the parts of the island which they inhabit, Dayak, Idaan, and Tiroon. Those which subsist by fishing are commonly called Biajoos. The appellations of Horaforas and Maroots have also been applied to these races. The whole may be considered as one, almost savage, and nearly similar to that which occupies the interior of Sumatra. Some, indeed, cultivate the ground, some display considerable industry in fishing, and a few employ themselves in collecting gold; but their institutions in general indicate the very rudest state of human society. It has been strongly asserted that they devour the flesh of their enemies; an assertion not noticed by Dr Leyden, and which has in many instances been made without foundation. All accounts agree, however, as to the existence of another truly savage custom, by which every man is debarred from the privilege of matrimony till he has, with his own hand, cut off the head of an enemy. Those, therefore, who are desirous of entering into that state form themselves into what Dr Leyden calls *head-hunting* expeditions. They make an inroad into the territories of a neighbouring tribe, and, if their strength appears sufficient, endeavour to effect their object by force; if otherwise, they conceal themselves behind thickets, till an unfortunate individual passes, whom they can make their prey. Some are also said to immolate human victims on the altars of their divinities.

The inhabitants of the towns along the coast consist chiefly of that race so universally diffused throughout the Indian islands under the name of Malays. This name, to an European ear, has usually suggested every extreme of perfidy and atrocity. We have perused, however, a very different estimate of their character, formed by an intelligent gentleman, who spent several years in this part of India. He describes them as honest, frank, simple, and even gentle in their manners, decidedly superior, in a moral view, to the degenerate Hindoos. The sanguinary deeds which have exposed them to so much reproach he ascribes to a proud and almost chivalrous sense of honour, which makes them regard blows, or any similar personal insult, as an offence only to be expiated by blood. The coarse and unfeeling treatment which they often experience from Dutch and Chinese masters drives them to these dreadful extremities. Piracy, however, is a vice of which this race cannot be acquitted; and the western coast of Borneo, situated on the great naval route to China, may be viewed as the grand field for its exercise. To a poor and hardy race, who see half the wealth of Asia passing along their shores, the temptation is almost irresistible. Like the Arabs, they have formed for themselves a code of morality, in which plunder is expunged from the list of vices. Yet, though individually brave, they possess no skill or discipline which could render them formidable to the crew of an European vessel. The cowardice of the Lascars, by whom Indian trading vessels are usually navigated, is the only circumstance which has made our trade suffer so severely from their ravages.

Next to the two classes above enumerated, the most numerous are the Chinese. These, by the gentleman above alluded to, are considered as the most valuable sub-

jects whom an uncivilized state can receive into its bosom. The difficulty of finding subsistence in their own country has led them to emigrate in vast numbers into Borneo. Nothing, perhaps, except the law which prohibits females from leaving the empire, could have prevented this almost unoccupied island from being entirely filled with a Chinese population. From this circumstance, however, the colonists are composed entirely of men in the vigour of life, and of the most enterprising and industrious character. Their chief settlement is at Sambas, on the western coast, where the numbers cannot be estimated at less than 30,000, composing a sort of independent state. Their almost sole occupation is that of extracting the gold which abounds upon this coast. It is found in alluvial soil, and is purified by the simple process of passing a stream of water over the ore. The processes employed for this purpose are daily improving, and it is conceived that the produce here and at other quarters will be sufficient to remove all future apprehensions of the East proving a drain upon the gold of Europe.

The commerce of Borneo, though not equal to its extent and natural capacities, is by no means inconsiderable. Gold is its principal export. Mr Milburn estimates the annual quantity exported at 200 peculs, or 26,000 lbs. avoirdupois, which would coin into upwards of 900,000 guineas. Like some other commodities, it is divided, by a grotesque scale, into three kinds, called the head, the belly, and the feet; the first being the best, and the two others gradually diminishing in value. Camphire is exported to the extent of thirty peculs (3990 lbs.), all to China, where it is more esteemed than that of Sumatra. The singular Chinese luxuries of *biche de mer* or sea slug, and edible bird-nests, are found in Borneo, as over all the Indian Archipelago. Pepper to a considerable amount, canes and rattans of various descriptions, sago, and a little tin, complete the list of exports. The chief import is opium to a very great extent, with piece-goods, hardware, coarse cutlery, arms, and toys. By far the greater proportion of the trade is in the hands of the Chinese. (Leyden's Description of Borneo, in the *Asiatic Journal*; Hamilton's *Gazetteer*; Milburn's *Oriental Commerce*; MS. of a Gentleman long resident in India.)

BORNOU, an extensive kingdom, situated in the eastern part of interior Africa. With the exception of Houssa, now subject to the sultan of the Fellatahs, it is superior in power and influence to any other state in that quarter of the continent. Major Denham, to whom we are indebted for the only full and authentic description of this country, places it between the 12th and 18th degrees of east longitude, and the 10th and 15th of north latitude, which would form an extent of nearly 400 miles in every direction. His own map and description, however, obliges us to restrict these dimensions to little more than one half. Bornou is bounded on the west by Soudan or Houssa, on the east by the lake Tchad, on the north by the Great Desert, on the south by the kingdoms of Begherme, Loggun, and Mandara.

The grandest natural feature of this country consists in the lake called the Tchad, one of the largest expanses of fresh water in the world, and well entitled to the appellation of an inland sea. Its limits have not been very precisely ascertained, but cannot fall much short of 200 miles in length and 150 in breadth. A remarkable variation, however, takes place, according as the rivers by which it is fed are swelled by the tropical rains, or their channels reduced by the continuance of the dry season. At this period the waters on every side recede, and leave uncovered a tract of many miles in extent, to be again overflowed when the rains have swelled the lake. The inhabitants, however, derive little advantage from the short and precarious interval during which they

Bornou.

Bornou.

have access to this portion of their territory. There is neither leisure nor opportunity to bring it under regular culture; and the luxuriant fertility derived from the inundation is wasted in producing a rank vegetable growth of grass from ten to twelve feet in height, with impenetrable thickets of trees and underwood. Man scarcely dares to penetrate into these gloomy regions, which are filled by numerous and formidable wild animals, elephants, lions, hyenas, and enormous broods of the serpent species. These creatures, when the inundation comes on, seek refuge in the cultivated and inhabited tracts, where their arrival diffuses consternation and dismay.

The rivers by which this great expanse of water is fed are the Yeou and the Shary. The former, which enters it from the west, excited great interest on its first discovery, from being considered, or at least suspected, to be a continuation of the Niger of Park. Further observation has completely disproved this supposition, and shown it to be a river of only secondary magnitude. Rising in a range of hills to the south of Houssa, it flows first north, then eastward through Bornou, till it falls into the Tchad; but it never, unless when swollen by the rains, presents any great body of water. The Shary is a more considerable stream, although its origin and early course are known only by conjecture. After flowing from the south for about forty miles, through the kingdom of Loggun, it enters at the south-eastern extremity of Bornou into the great common receptacle, where it forms a noble stream, half a mile broad, and flows with considerable rapidity.

The territory of Bornou, extending along the whole western and part of the southern and northern shores of the great lake, is generally level and fertile. The climate, especially from March to the end of June, is oppressively hot, rising sometimes to 105 and 107, and even during most of the night not falling much below 100. In May the wet season commences, with violent storms of thunder and lightning. In the end of June the rivers and lakes begin to overflow, and for several months the rains are almost incessant, accompanied with damp, cloudy, and sultry weather. The inhabitants at this season are severely afflicted with fever and ague, which carry off great numbers of them. In October the rains abate; cool, fresh winds blow from the west and north-west; and for several months the climate is both healthful and agreeable.

No mention is found of Bornou among the geographers of antiquity, although it may be conjectured that the great lake of Nigritia, placed by Ptolemy in the centre of Africa, was perhaps the Tchad. Edrisi, however, in the twelfth century, describes this country under the appellation of Kuku, which is still borne by its capital. He represents the king as absolute and powerful, with a numerous army and many attendants; the people as martial, though rude; and the merchants as carrying on an active trade and possessing great wealth. Leo, who visited it about two centuries after, gives a description nearly similar. The people are represented as Pagans, and extremely rude, though numerous, and the country well cultivated. The merchants from Barbary supplied the king in his expeditions with arms and horses, while he made an annual expedition to procure slaves to be given in payment.

No further relations respecting Bornou were communicated to Europe during a very long period; yet it is remarkable that, in the maps of Sanson, Delisle, and others of the sixteenth and seventeenth centuries, there is found a lake of Bornou, and in some of them a large lake with the name of Guardia, which does not sound very dissimilar to that of Tchad. It is difficult to conjecture the ground upon which these features were delineated; yet their coincidence with those recently discovered seems to show that they were founded upon some information with which we

are now unacquainted. D'Anville, however, proceeding upon his rigid principle of admitting no object for which he could not find a positive authority, expunged these names from his map, and has been generally followed by modern geographers.

When the African Association in 1788 commenced their operations, they early received some information, collected by Mr Lucas at Tripoli, with other particulars related by Ben Ali, a Moorish merchant resident in London. From these sources were derived pretty copious notices, both concerning Bornou and Cassina; the former being described as what it then appears to have been, decidedly the ruling power in the interior of Eastern Africa, all the kingdoms of which it had reduced into a state of vassalage. In arranging these accounts, however, a considerable error was committed as to the position of this country. Mr Lucas had been informed that it was fifty journeys, or about six hundred and fifty miles, south from Fezzan; but his informant added that it was only twenty-five journeys west from the Nile. To meet this statement Major Rennell conceived it necessary to extend the route, not due south as it really was, but south-east, so as to place it in the heart of the desert, seven degrees north and eight degrees east of its real position. Kuku, likewise believed, from the statement of Edrisi, to be a separate kingdom, was placed in the same quarter, still nearer to the Nile; and thus the desert tract to the west of Nubia was filled with countries which, in that quarter, have no existence.

The expedition sent out by the British government in 1822, under Denham and Clapperton, completely adjusted the geography of this part of the continent. It was discovered that Bornou, instead of being so far removed, as our maps represented, from Houssa and Cassina, was close on their eastern frontier, and formed a continuation of that extensive, fruitful, and finely watered plain, which extends from the mouth of the Senegal across Central Africa. Its relative political circumstances had also undergone, during this interval, a very complete change. Instead of holding all the surrounding states in vassalage, it had been itself completely subjected to the dominion of the Fellatahs, who, after subjugating all Houssa, had invaded Bornou, and committed the most dreadful ravages, destroying its capital and other large cities, and bringing the whole country into a state of entire bondage. There was still, however, among the people a strong spirit of valour and independence. A mere private individual, in the northern province of Kanem, pretending to, and perhaps himself trusting in, a celestial mission, hoisted the green flag of the Prophet, and, under the title of the servant of God, undertook a series of struggles for the deliverance of his country. The Fellatahs appear to have been taken very much by surprise, and, being defeated in successive encounters, were in ten months driven completely out of Bornou. They seem to have now given up all attempts at reconquering it, although a hostile spirit still reigns between the two countries.

The conqueror, called, from his native province, El Kanemy, having the army wholly devoted to him, might probably have with little difficulty assumed the sovereign power. More moderate, and perhaps more prudent, he drew forth the nearest heir of the ancient sultans, and invested him with all the appearance and pomp of sovereignty; reserving only for himself, under the title of scheik, all its reality. The court of the sultan was established at New Bornou, which was made the capital, instead of the old city, which had been entirely destroyed during the Fellatah invasion; while the scheik, in military state, resides at the city of Kuku or Kouka.

The Bornouese throne in former times had been elective, at least among the members of the same family; and

Bornou.

Bornou.

the nobles possessed this and other high privileges: but at present the scheik possesses a power nearly absolute, which he exercises with salutary vigour. Bands of robbers who desolated the country have been nearly extirpated, and travelling and property rendered secure, at least in the interior. Justice within each city is administered, as in other Mussulman countries, by the *cadi*, with an appeal to the scheik. Murder is punished, on conviction, by delivering the offender to the relatives of the deceased, who dispatch him with clubs. A young thief is buried in the ground up to the head, which being covered with butter and honey, is exposed under the burning sun to the attack of innumerable flies and mosquitoes. Insolvent debtors are rather hardly dealt with. But the scheik's zeal was peculiarly directed against moral offences, of which conscience and public opinion have been generally considered as the most appropriate guardians. Such were the non-observance of the Mahommedan fasts, upon which severe and relentless penalties were levied. He was also most strict in punishing those failings in the female sex which are elsewhere considered as sufficiently visited by disgrace and exclusion from society. Here not only the most ignominious punishments, but often death itself, awaited them. On one occasion sixty of these unfortunate offenders were brought before him, of whom five were hanged, and four whipt so severely that two afterwards expired; an outrageous virtue, which seems with reason to have been branded as almost diabolical. The most frivolous female offences, as talking too loud, and walking in the street with the face unveiled, were considered as ground of public indictment at this severe bar. Even the spending in courtship or otherwise a larger sum than a man was supposed to be able to afford, gave ground for dragging him before the national tribunal. Major Denham saw one thrown into prison for presenting to his bride two robes or *turkadoes*, when his station was considered as not authorizing more than one; although he proved that the lady had refused her consent on any other terms; which, however, drew upon her also a severe animadversion.

The sultan of Bornou is surrounded by a mounted body-guard, who likewise compose his principal nobles and chiefs. Their attire and equipment is the most grotesque and unwieldy, perhaps, to which fashion in any country has given rise. It is indispensable to the chief of rank that he should possess a huge belly, the singular importance attached to which is probably founded on the idea of its being an indication of plenty and luxury; and it is held so essential, that even when high feeding cannot produce the effect, stuffing is employed to give the appearance of it. Again, even in this burning climate, the body is enveloped in successive robes, amounting often to ten or twelve, the number being always considered as indicating the rank of the wearer. The head likewise is inclosed in numerous successive turbans, which are supposed to be rendered more ornamental by leaving only one side of the face uncovered. The sultan studies to be still more protuberant and more loaded with clothing than any of his courtiers. Yet in this attire he and they advance together into the field; but of course they can have no real efficiency in the duties of active warfare. The last sultan had fallen in consequence of the impossibility, caused by his ponderous equipment, of flying with sufficient speed before a victorious enemy.

The military force of Bornou consists almost entirely in cavalry, amounting to about 30,000, who are mounted on small but active steeds, which, as well as their riders, being cased in iron mail, present a very formidable appearance. They also manage their horses with the utmost skill, and perform all the manœuvres of the field most

rapidly and dexterously. Their only defect is, that when placed in the field against an enemy at all formidable, they can by no impulse be induced to fight. They look on as spectators till the contest issues in victory, when they engage eagerly in pursuit and plunder, in both of which they excel; whilst, in case of defeat, they take to flight with the utmost rapidity. As, however, the cavalry of the armies with which they contend are nearly on a level in point of prowess with themselves, the match is tolerably equal. There are usually on each side about a hundred chiefs, raised to distinction by bodily strength and prowess, who engage in single combats, and display often the most desperate valour. Barca Gana, the scheik's general, had obtained the reputation of possessing charms that rendered him invulnerable. The main dependence of that prince is upon a body of 9000 spearmen from his native territory of Kanem, who rally round him with the most enthusiastic attachment. Though almost naked, and equipped only with shield and spear, they display a discipline beyond that of almost any other African army. They march by tribes, and keep in front of their line a regular chain of piquets, with sentinels, who every half hour pass the war-cry along it; precautions very rarely employed in barbarian armies. All the sovereigns of Central Africa likewise consider themselves fortunate if they can engage the services of even a small party of Arab caravan followers, who, being brave and armed with muskets, an instrument yet almost unknown in this region, are objects of something like supernatural dread.

The territory of Bornou is fertile and well watered, yielding large crops even under very imperfect cultivation. The labour is chiefly performed by female slaves, who, at the commencement of the rainy season, scratch rather than turn the ground, and scatter rather than sow the seed. They are also obliged to watch the growth, in order to guard against numerous animal depredators; a very perilous occupation, in the course of which they are liable to be carried off by the wild beasts, who are roaming about in every direction. The rice and wheat are inferior, and grown in small quantity. The grain which forms the staple food of the people is a species of millet called *gussub*, which they form, not into bread, an article here entirely unknown, but into a species of paste, that, by the addition of butter and honey, forms the highest boast of Bornou cookery. Cotton and indigo are also valuable productions, affording the material for the cloths finely dyed with blue stripes, which form the staple fabric of the country. All the domestic animals are reared, and very numerous herds of oxen are possessed, chiefly by an Arab tribe called *Shouaas*. Major Denham reckons 20,000 on the shores of the Tchad, and double that number on the banks of the Shary. The empire, however, is remarkably destitute of the products of horticulture. There is neither a fruit nor a vegetable, except some onions in the vicinity of the large towns, and a very few limes and figs reared with great difficulty in the garden of the scheik.

The wild animals are very numerous, finding both food and cover in the extensive woody and marshy districts. Lions prowl about in considerable numbers, approaching even the walls of the towns. The Bornouese delight in taming and even making a pet of this noble animal. The scheik, as a special favour, sent Major Denham a present of a young lion, which he very prudently returned, lamenting the want of space for his accommodation. Elephants, in herds of fifty to four hundred, wander over the tract inundated by the Tchad, and are hunted and killed both for the flesh and the ivory. Hyenas also, in huge and formidable bands, invade the cultivated fields, and are with difficulty prevented from penetrating

Bornou.

Bornou. into the towns. The tall form of the giraffe is not unfrequently seen cropping the leaves of the dense forest. The waters abound with crocodiles and hippopotami, and the flesh of both is valued for food; that of the former, indeed, is described by naturalists as extremely delicate. The country is filled with swarms of bees, which often obstruct the passage of the traveller; and the honey, though only partially collected, forms one of the chief Bornouese delicacies. Antelopes, gazelles, ostriches, and various other quadrupeds and feathered animals, are pursued as game.

The population of Bornou is calculated by Major Denham at 5,000,000; but, considering its limited extent, and the imperfect state of agriculture, this number must, we think, be considerably exaggerated. The leading people, called Bornouese or Kanowry, present a complete specimen of the negro form and features; having large mouths, thick lips, broad noses, an unmeaning face, but good teeth and high foreheads. The females heighten their want of beauty by a most extensive and injudicious system of puncturing and tattooing. The people are peaceably disposed, friendly and courteous in their manners, and distinguished by a sort of good-natured heaviness. Though endowed with a slender degree of courage, they are resentful, and addicted to petty larcenies. The law allows of polygamy, but the richest have seldom more than two or three wives, and the rest of the community only one. The favourite amusement is wrestling, not performed in person, but viewed as a spectacle while performed by slaves taken in war from the neighbouring nations, particularly the Beghermes and Musgows. The displays of strength made by these men are said to be often very extraordinary. A powerful wrestler sells at a high price, and the masters place extraordinary pride in the performance of their slaves, cheering them during the combat, and, on its successful issue, often presenting them with valuable robes. Even the ladies of Bornou engage occasionally in public contests, where they often throw each other with violence to the ground. Another favourite amusement consists in a rude game bearing some resemblance to chess, played with beans and holes in the sand.

The Mahomedan religion is universally professed in Bornou, and even with violence and bigotry. Through recommendations brought with them, the English travellers secured good treatment; but, as unbelievers, they were viewed with the deepest horror, and almost as a species of monsters. Even from those who showed at first the most friendly disposition, the disclosure of their creed drew forth deep groans, sometimes screams, and usually arrested all progress to intimacy. A man who had served them for two or three weeks, although he pleaded that it was only under the most extreme necessity, was declared unfit on that ground to be received as a witness in a court of law. There are resident in Bornou a considerable number of *fighis* (writers or doctors), who have visited Mecca, and are well skilled in Arabic. It is even an employment to write copies of the Koran, which are sent into Barbary, where they bear a considerable price. Its verses are much used as charms or amulets, in the preparation of which the scheik was understood greatly to excel, gaining almost as many victories by his pen as by his sword. The Bornouese, like other negroes, have songs relating to love or war, some of which are said to possess merit; but their intellectual character in general seems to rank extremely low.

The pastoral districts of this country are occupied by a tribe called Shouaas, who are accounted Arabs, and speak that language, though they have scarcely any resemblance to those in the north bearing that appellation. They have fine open countenances, with aquiline noses, large eyes,

and a complexion of light copper; and they exhibit a strong though improved resemblance to the European gipsies. Their deportment, however, is not very favourably spoken of. They do not want courage, and can furnish the government when necessary with 15,000 horse; but they are arrogant and deceitful, imposing upon the people by the manufacture of charms, and by pretensions to prophecy and fortune-telling. Having thus gained admission into the houses, they not only sell these gifts at a high rate, but embrace opportunities of pilfering. Probably they were observed to disadvantage in the heart of the cities. One of their tribes, called Dugganahs, who were visited in their native tents on the Shary, presented a most pleasing picture of patriarchal simplicity. Their countenances were noble and expressive, and the attachments of kindred and domestic affection were displayed in peculiar force. Another tribe, called the La Salas, almost independent of Bornou, inhabit a number of low islands in the Tchad, covered with rich pasture, and separated from the continent by channels so shallow as to be fordable on horseback. A knowledge of the tracts is however requisite; and those troops who without it attempted to penetrate through them have got entangled in mud, sunk into deep pools, and signally defeated.

The towns in Bornou are of considerable size, surrounded with walls thirty-five or forty feet in height, and twenty feet in thickness, having at each of the four corners a triple gate, composed of strong planks of wood, with bars of iron. The abodes of the principal inhabitants form an inclosed square, in which are separate houses for each of the wives; whilst the chief himself resides in two or more elevated structures resembling turrets, connected together by terraces. These are well built, of a reddish clay, highly polished, so as to resemble stucco; whilst the interior roof, though composed only of branches, is tastefully constructed. The horns of the antelope and gazelle are employed to fasten together the different parts, and have suspended from them the quiver, spear, and shield of the owner. The ordinary houses are small, being built partly of mud and thatched, partly only of straw or coarse grass mats. Major Denham was accommodated in one of eight feet diameter, having a hole two and a half feet high, by which he crept in and out; but this deficiency of aperture was rendered almost necessary by the crowds of tormenting insects who would otherwise have made good their entrance. Though New Bornou and Kouka were the residences, the one of the sultan and the other of the scheik, neither is equal in magnitude to Angornou, estimated to contain 30,000 inhabitants, who, on market days, are swelled to 80,000 or 100,000. On the Yeou are seen the ruins of Old Bornou and Gambarou, which appear to have been greater and better built cities than any now in the kingdom; but they had been so entirely destroyed by the Fellatahs in their late invasion, that the very site is in a great measure covered with shrubs and vegetation. The vicinity is almost laid waste by the inroads of the Tuaricks; and, indeed, all the kingdoms of Central Africa suffer the disadvantage of having their frontier exposed to the ravages of predatory tribes who occupy the rude and desert borders.

The English travellers have held out favourable hopes of the commerce which might be opened with Bornou. They observed the increased and increasing demand, among a numerous population, for goods which Britain either does or could produce cheaper than any other country; and these goods were found selling at an advance of 300 per cent. above their price at Tripoli. On the other hand, it must not be forgotten that the route from that city, though the nearest of any from the coast, greatly exceeds a thousand miles, through the most dreary and desolate tracts, amid the domains of numerous predatory tribes.

Borodino
||
Borough.

The merchant has to encounter, therefore, not only accumulated hardships, but all the perils of famine, battle, and pestilence. It would be vain, therefore, to expect that any one would conduct such a trade without very high profits. It is at present carried on by merchants, or rather chiefs, each with a large body of armed followers, alike prepared for commerce or war. The European who should engage in such a trade would be obliged to follow this example, and might expect to encounter their enmity and rivalry. It seems doubtful, therefore, how far such a trade could now be carried on by any other than its present channel.

Amongst the commodities which find a market in Bornou are mentioned writing paper, beads, coral, silks and cottons of gaudy patterns, turbans, small carpets, brushes, caftans, and shirts ready made; brass basons tinned, small mirrors, pistols, and other arms ornamented, but cheap. The commodities taken in return are almost exclusively slaves, obtained by purchase or capture; and we fear it will be more difficult than Major Denham supposes to divert the trade from this bad channel. Neither gold nor silver are seemingly to be procured in Bornou. Elephants' teeth, ostrich feathers, raw hides, musk, indigo, and senna, are mentioned as commodities suited to the market of Europe.

(E.)

BORODINO, a village in Russia, near the river Moskwa, about ninety miles west of Moscow, remarkable for the terrible battle fought there on the 7th of September 1812, between the French and Russians, in which the latter were defeated.

BOROMÆUS. See BORROMEUS.

BOROUGH, BURROUGH, *Borow*, or *Burgh*, is a term frequently used for a town or corporation which is not a city.

BOROUGH, in the original Saxon *borge* or *borgh*, is by some supposed to have primarily meant a tithing or company consisting of ten families, who were bound and combined together as sureties for one another. Afterwards, as Verstegan informs us, borough came to signify a town that had something of a wall or inclosure about it; so that all places which amongst our ancestors had the denomination of borough, were one way or other fenced or fortified, being, as it were, *πυργιοι*. But in latter times this appellation was also bestowed on several of the *villæ insigniores*, or country towns of more than ordinary note, though not walled.

The ancient Saxons, according to Spelman, gave the name of burghs to what in other countries were called cities. But different canons being made for removing the episcopal sees from villages and small towns to the chief cities, the term *city* came to be attributed to episcopal towns, whilst that of borough included all the rest, even although they had the appearance of cities, as being governed by mayors, having bye-laws of their own making, sending representatives to parliament, and being fortified with a wall and castle, and the like.

Royal *BOROUGHs* or *Burghs*, in Scotland, are corporations originally created for the advantage of trade, in virtue of charters granted by several of their kings, and having the privilege of sending commissioners to represent them in parliament, besides other peculiar privileges. The royal burghs are not only so many distinct corporations, but also constitute one entire body, governed by, and accountable to, a general court, anciently called *the court of four boroughs*, which was held yearly, to treat and determine concerning matters relating to the common interest. The four burghs which composed this court were, Edinburgh, Stirling, Roxburgh, and Berwick; but the two last falling into the hands of the English, Linlithgow and Lanark were substituted in their room, with a saving to the former

whenever they should return to their allegiance. But this court not being sufficient to answer the necessities of the royal burghs, they were all empowered under James III., in 1487, to send commissioners to a yearly convention of their own, which was then appointed to be held at Inverkeithing, but is now held at Edinburgh, under the denomination of the Convention of Royal Burghs, which was vested with great powers, and had for its object the benefit of trade, and the interest of the burghs generally.

Borough-English, a customary descent of lands or tenements, in some ancient boroughs and copyhold manors, by which the youngest son, and not the eldest, succeeded to the burgage tenement on the death of his father.

BOROUGHBRIDGE, a borough and market-town in the parish of Aldborough and west-riding of Yorkshire, 208 miles from London, on the river Eyne, which is navigable to this place. The market is held on a Saturday. The number of inhabitants in 1801 amounted to 680, in 1811 to 745, and in 1821 to 860.

BOROWITSCHI, a circle of the Russian government of Novogorod, extending over 18,796 square miles, containing one city and fifty-four parishes, with 91,720 inhabitants. The chief place is a city of the same name, on the river Msta, containing two churches, 860 houses, and 3500 inhabitants, amongst whom are many pilots employed in interior navigation. Long. 33. 5. E. Lat. 58. 16. N.

BOROWSK, a circle in the Russian government of Kaluga, 614 square miles in extent, with 78,400 inhabitants. The chief place is the city of the same name on the river Protwa, a manufacturing place for linen goods, with a population of about 7000 persons. Long. 36. 5. E. Lat. 55. 14. N.

BORRELISTS, in *Ecclesiastical History*, a Christian sect in Holland, so denominated from their founder Borrel, a person of much learning in the Hebrew, Greek, and Latin tongues. They rejected the use of the sacraments, public prayer, and other external acts of worship; affirming that all the Christian churches of the world have degenerated from the pure apostolical doctrines, because they have suffered the word of God, which is infallible, to be expounded, or rather corrupted, by doctors, who are not infallible.

BORRICHIOUS, OLAUS, one of the most learned men of his age, the son of a Lutheran minister, was born in 1626, at Borchén in Denmark. He was sent to study physic in the university of Copenhagen in 1644, and he began to practise during a terrible plague which made great havoc in that city. In 1660, although appointed professor of botany and chemistry, he visited Holland, England, and France; was received as doctor at Angers; and visited Rome in 1665. In the course of his travels he attended the most celebrated schools, and was selected by Queen Christina as her master in chemistry. He returned to Copenhagen in 1666, and discharged the duties of his office with great assiduity, as his works abundantly testify. He was raised to the office of member of the supreme council of justice in 1686, and to that of counsellor of the royal chancery in 1689; and he died of the operation of lithotomy in 1690. The following is a list of his works: 1. *Dokimasia Metallica*, Copenhagen, 1660, 8vo; 2. *De Ortu et Progressu Chemicæ Dissertatio*, ibid. 1668, 4to; 3. *Hermetis, Ægyptiorum, et Chemicorum Sapientia*, ibid. 1674, 4to; 4. *Lingua Pharmacopœorum*, ibid. 1670, 4to; 5. *Cogitationes de variis Linguae Latine Ætatis*, ibid. 1675, 8vo; 6. *De Causis diversitatis Linguarum*, ibid. 1675, 4to; 7. *De Somno et Somniferis*, Francfort, 1680, 1683, 4to; 8. *De Usu Plantarum Indigenarum in Medicina*, Copenhagen, 1688, 1690, 8vo; 9. *Dissertationes V. de Poetis Græcis et Latinis*, ibid. 1676; 10. *Conspectus Chemicorum Scriptorum Illustriorum*, ibid. 1696, 4to; 11. *De An-*

Borromean Islands. *tiqua Urbis Romæ Facie*, ibid. 1697, 8vo; 12. *De Urbis Romæ Primordiis*, ibid. 1687, 4to; with some trifles not worth particularizing.

BORROMEAN ISLANDS. Not far from the south-eastern termination of the Alps there is a lake called Lago di Locarno, or Lago Maggiore, extending above fifty miles in length by five or six in breadth. It contains several islands, amongst which are the Isola Bella and Isola Madre, situated in a large bay towards the west, and designed the Borromean Islands. Towards Switzerland the lake terminates in a canal, which is of much utility for commercial purposes; and near Cesti, which is ten leagues from the city of Milan, it discharges itself into the river Ticino, with a current rapid and dangerous to the navigation of small vessels. The Borromean Islands lie about fifteen miles distant by water from Cesti, and the passage to them displays a succession of curious and interesting objects, some of which are connected with their own history. Amongst these may be mentioned a colossal bronze statue of San Carlo Borromeo, above the small town and port of Arona, which is sixty feet in height, and stands on a pedestal of proportional dimensions. This gigantic image was cast at Milan, and brought hither in pieces. The Borromean Islands are of inconsiderable size, but the artificial decoration they have received has been the admiration of spectators since the middle of the seventeenth century, when both were barren and unprofitable rocks. About this time Vitaliano, Count Borromeo, a nobleman of illustrious descent, and master-general of the ordnance to the king of Spain, resolving on their embellishment, directed that they should be covered with earth from the neighbouring banks of the lake. His injunctions were fulfilled, and, at an immense expense, the islands were converted into two gardens. Isola Madre appears in ten successive terraces, rising one hundred and thirty feet above the level of the water, each regularly decreasing in size from the base to the summit, which is an oblong surface, seventy feet by forty in extent, paved and surrounded by a balustrade. The whole are environed by gigantic marble statues of gods, goddesses, and horses, or other figures; and the walls are clothed with the finest fruit trees and evergreens, many of which belong to the southern climates. There is, besides, a magnificent palace towards the western end of the island, close to the lake, which almost washes its walls. It is built on arches, which are formed into grottoes, with a floor of Mosaic, representing various objects, and decorated also with shell-work and marble. The palace itself contains a profusion of marbles and paintings; and some flower-pieces, executed on marble, have been particularly admired, as also busts and statues. At the angles of the garden, which has a southern exposure, there are two round towers with lofty chambers adorned with red and white marble; and in the vicinity are groves of laurels, orange-trees, lofty cypresses, and other odoriferous plants, rendering it a delightful retreat. But much of the embellishment is lost by the immediate neighbourhood of a miserable hamlet.

Isola Madre, which is the larger of the islands, is between one and two miles from Isola Bella; it consists of a superstructure of seven terraces, apparently lower, but not less beautiful, than the other. However, it is of equal height in reality, the base being a perpendicular rock, rising considerably out of the water, and on that account not requiring so much covering. Here also there is a palace embellished with paintings and different ornaments; and in the gardens are groves of citrons, cedar, and orange-trees, besides a summer-house close to the lake. But all the decorations, as before, are necessarily on a limited scale, from the size of the island; and it excites the wonder of the spectator, that in a space thus restricted so

much has been done. Pheasants were formerly bred in this island, as they were deterred by the vicinity of the water on all hands from attempting to escape. There were some hydraulic exhibitions in Isola Bella, and large cisterns or reservoirs to preserve them in action. When any foreign prince visited these islands in the night, or resided upon them, they were illuminated with various coloured lights. Their decorations were not only completed at an enormous expense, but to keep them in the same state since 1671, about which time they seem to have been finished, the charge has proved equally great. They are frequently called the "Enchanted Islands." Keyser, a learned traveller, says, "these two islands can be compared to nothing more properly than two pyramids of sweetmeats, ornamented with green festoons and flowers." And a later tourist, Coxe, who borrows largely from him, in speaking of the Isola Bella, observes, "if any thing justly gives this island the appellation of enchanted, it is the prospect from the terrace. The gradual diminution of the mountains, from the regions of eternal snow to the rich plain; the sinuosity of the lake; its varied banks; the bay of Marozzo, bounded by vast hills; the neighbouring borough of Palanza, and more distant view of Laveno, the numerous villages, the Isola Madre, and another island sprinkled with fishermen's huts, form a delightful assemblage."

These islands, after passing from the family of Borromeo, appear to have come into possession of the emperor of Germany. More recently, both of them, together with the western coast of the bailliage of Locarno, are said to have been ceded by the empress Maria Theresa to the king of Sardinia, in consideration of the assistance she had derived from him. The whole lake is environed by hills, covered with vineyards, and interspersed with summer-houses; beautiful rows of trees traverse its banks, and the scene is still further embellished by cascades falling from the mountains.

BORROMEUS, ST CHARLES, cardinal, and archbishop of Milan, was the son of Gilbert Borromeo, count of Arona, and of Mary of Medicis, and was born at the castle of Arona, upon the Lago Maggiore, in the Milanese, on the 2d October 1538. When he was about twelve years old, Julius Cæsar Borromeus resigned to him an abbacy, which was considered as an hereditary appurtenance of the family; and Charles accepted the benefice, but applied the revenue wholly in charity to the poor. Having acquired a sufficient knowledge of the languages at Milan, he studied the civil and canon law at Pavia; and derived great advantage from the company and conversation of Francis Alciat, one of the most learned men of the age. In the year 1554 his father died, an event which recalled him to his native place, Arona, where, although he had an elder brother, Count Frederick, he was requested by the family to take the management of their domestic affairs, which he at length consented to do.

After a time however he resumed his studies, and, in the year 1559, being then just twenty-one, he took his doctor's degree. The promotion of his uncle Cardinal de' Medicis to the pontificate, by the name of Pius IV. which happened the year following, seemed to have little effect upon him; but he was soon made prothonotary, intrusted with both the public and privy seal of the ecclesiastical state, and created cardinal deacon, and soon after archbishop of Milan. In compliance with the wish of his uncle the pope, he lived in great splendour, having a brilliant retinue and a large number of domestics; yet his own temperance and humility were never brought into question. In order to render even his amusements useful, he established an academy of select and learned persons, each of whom was to write on some chosen subject,

Borromeus.

Borro-
meus.

either in verse or in prose, and to communicate to the others in frequent conferences the fruits of his studies. The works produced by this society have been published in several volumes, under the title of *Noctes Vaticanae*, printed at Venice in 1748, because these useful assemblies were held at the Vatican, in the evenings, after the business of the day had been concluded. About this time he also formed a design of founding a college at Pavia, and in prosecution of this design raised a large edifice upon the foundations of several houses which belonged to the Borromeo family in that city. He also obtained from the pope several benefices, which he attached to his establishment; he provided it, out of his own private income, with every thing necessary for the young scholars; and he dedicated the college thus founded to Justina, virgin and martyr.

Upon the death of his elder brother Frederick, his relations, friends, and even the pope himself, advised him to change his state, quit the church, and marry, that his family might not become extinct. Contrary to this advice and the expectations of the world, however, Charles addressed the pope in these terms: "Do not complain of me, holy father, for I have taken a spouse whom I love, and on whom my wishes have long been fixed." From this time he became more fervent in the exercises of piety, and more zealous for the advancement of ecclesiastical knowledge.

A very intimate friendship subsisted between Borromeus and Don Barthélemy des Martyrs, archbishop of Prague, and author of a book entitled *Stimulus Pastorum*. This work falling into the hands of Borromeus, inspired him with an earnest desire to become a preacher, more especially as he was now convinced that predication was one of the principal duties of a prelate. Multiplicity of business, ill health, a feeble voice, and a difficult pronunciation, formed no inconsiderable obstacles to the success of his design, yet he at length surmounted them all; and although his beginnings were weak, perseverance enabled him ultimately to attain the object of his ambition. Meanwhile a change in the state of his relations with the holy see was at hand.

Pius IV. died on the 7th of January 1566, and twenty-eight days thereafter Cardinal Alexandrine mounted the papal throne under the title of Pius V., the skill and diligence of Borromeus having very materially contributed to stifle the cabals of the conclave. As soon as this event took place, and tranquillity had been re-established at Rome, which was generally disturbed by such elections, Borromeus gave himself wholly up to the reformation of his diocese of Milan, where the most flagitious irregularities were openly practised, and where, from the ignorance of the secular clergy, the insubordination of the regulars, the superstitious practices introduced into public worship, the scandalous negligence exhibited in the administration of the sacraments, and the gross abuse of all the functions of the holy ministry, matters had fallen into a most deplorable state. The archbishop began by making pastoral visits in his metropolis, where the canons were by no means distinguished for the purity of their manners. By a variety of wise and necessary regulations, he soon restored proper decency and dignity to divine service. In conformity to the decrees of the council of Trent, he cleared the cathedral of the gorgeous tombs, rich ornaments, banners, arms, and in general of all the trophies with which the vanity of man had disfigured the house of God; and in order to give a sanction to his reform by a decisive example, he spared not the monuments of his nearest relations. Nor did his zeal stop here. He divided the nave of the church throughout its whole length into two compartments, so that the sexes, being separat-

Borro-
meus.

ed, might perform their devotions without any attention to each other, and with feelings and impressions suitable to the place. From the cathedral he proceeded next to the collegiate churches, and even to the fraternities of penitents, particularly that of St John the Baptist. The duty of this society was to attend criminals to the place of punishment, and to assist, comfort, and prepare them for death; but the spirit of the institution had been forgotten, and the wretches condemned to death were dragged to execution like beasts, without spiritual assistance or consolation. The archbishop revived the original fervour of the order, and persuaded many of the nobility and principal persons of the city to become members of a society appropriated to so eminent a branch of Christian charity. The reformation of the monasteries followed that of the churches; and the vigilance of the archbishop soon extended itself from the city to the country round it, which abounded with irregularities requiring correction. The great abuses which had overrun the church at this time arose principally from the ignorance of the clergy. In order, therefore, to attack the evil at its root, Charles established seminaries, colleges, and communities, for the education of young persons intended for holy orders. He met with many difficulties and much opposition in his endeavours to bring about a reformation of manners; but by an inflexible constancy, tempered with great sweetness of manners, he prevailed against every obstacle, and succeeded in rendering the most important services to the cause of morals as well as religion.

But the governor of the province, and many of the senators, were apprehensive that the cardinal's ordinances and proceedings would encroach upon the civil jurisdiction, and become inconsistent with the rights of his Catholic Majesty, to whom the duchy of Milan then belonged. And this proved a fruitful source of remonstrances, representations, and complaints, addressed to the courts of Rome and Madrid; these, however, in as far as concerned the king of Spain, Philip II. were referred entirely to the decision of the pope. But Borromeus had more formidable difficulties to struggle with, in the inveterate opposition of several religious orders, particularly that of the Brothers of Humility. Three provosts of the society entered into a conspiracy to cut him off; and one of their confederates, Jerome Donat, surnamed *Farina*, took upon him to carry the design into execution. For this purpose he mixed with the crowd which repaired to the archiepiscopal chapel, where the cardinal spent an hour every evening in prayer with his domestics and other pious persons; and having watched his opportunity, he fired at his eminence a harquebuss, loaded with a ball suited to the calibre of the piece, and with a considerable charge of leaden shot besides. It is said that the ball struck him on the spine, but dropped at his feet without doing any other damage than ruffling his rochet, and that one of the shot penetrated his clothes to the skin, and there stopped, without imprinting any wound; which was considered a miracle, especially as another shot tore away part of a wall, and went quite through a table. Without having recourse to such a solution, his escape is certainly wonderful, considering that the assassin had taken his station at the distance of only five or six paces from his intended victim. At the moment when the shot was fired the choir were chanting the fine old melody, *Non turbetur cor vestrum neque formidet*; and it is said, that after the discharge of the piece the cardinal archbishop continued the service without any apparent emotion. The assassin and three of his accomplices were seized, tried, condemned, and executed, notwithstanding every effort of the cardinal to screen them from the punishment which they so well merited.

Borrows-
tounness.

In the year 1576 the city and diocese of Milan were visited by the plague, which swept away great numbers. On this occasion the behaviour of Borromæus was truly Christian and heroic. He not only continued on the spot, but went about giving directions for accommodating the sick and burying the dead, with a zeal and attention that were at once ardent and deliberate, minute and comprehensive; and his example stimulated others to join in the good work. He avoided no danger, and he spared no expense; nor did he content himself with establishing proper regulations in the city, but went out into all the neighbouring parishes where the contagion raged, distributing money to the poor, ordering proper accommodations for the sick, and punishing those, especially the clergy, who were remiss in discharging the duties of their calling. But notwithstanding the fatigue and perplexity which he suffered in thus executing his pastoral charge, he abated nothing of the usual austerity of his life, nor omitted any of his stated devotions; whatever approached to luxury or magnificence he considered as incompatible with the propriety of his character; bread and water constituted his humble and daily fare.

But continual labours and austerities at last shortened the life of this remarkable man. Having gone to Verceil to put an end, if possible, to divisions which threatened the most fatal consequences, he there received a message from the duke of Savoy, requesting his presence at Turin, whither he immediately repaired. From Turin he retired to a place called the Sepulchre, on the mountain Vairais, where being seized with an intermittent fever, he returned to Milan, and died there on the 4th of November 1584, the day after his return. Borromæus was canonized on the 1st of November 1610, in the pontificate of Leo XI. Besides the *Noctes Vaticanæ*, to which he appears to have contributed, the only literary relics of this intrepid and zealous reformer are some homilies, discourses, and sermons, with a collection of letters. Several lives of him have been published. That by Godeau, however, is too succinct; that by Touron, a Dominican, is too diffuse; and that by Ribadeneira, a Spanish Jesuit, is filled with incredible and ridiculous fables. But through all the mist of absurdity and superstition in which the character and actions of Borromæus have been involved, it is easy to discern, that if the Church of Rome had had many such men, religion might have been spared some grievous wounds, and the nations of Europe many afflicting and sanguinary convulsions.

BORROWSTOUNNESS (generally abbreviated to Bo'ness), a sea-port town of Scotland, in the county of Linlithgow, is situated on the southern shore of the Frith of Forth, where that arm of the sea is between three and four miles broad. This is one of the most ancient sea-port towns of Scotland, and many of the houses appear to be of very ancient date. The town is irregularly built; the streets are narrow and incommodious; and, from the number of public works, whence smoke is profusely emitted, the houses are for the most part coated with soot. There is an excellent harbour here, where a patent slip is erected for the use of shipping. The trade of this port was at one time considerable; but of late years it has much declined, in consequence of the navigable canal between the rivers Forth and Clyde having gradually transferred the trade to Grangemouth, which stands at the junction of this canal with the Forth. At present it possesses three vessels employed in the whale-fishery. The parish contains extensive coal-works. There are also two distilleries, a pottery, a soap-work, and a vitriol and sal-ammoniac work. Besides the established church, there is a dissenting meeting-house. There are two weekly markets, and an annual fair. The population in 1831 amounted to 2809.

Borrowstounness is distant eighteen miles west of Edinburgh, and three north of Linlithgow.

BORSEHOLDER, among the Anglo-Saxons, one of the lowest magistrates, whose authority extended only over one free burgh, tithing, or decennary, consisting of ten families. Every freeman who wished to enjoy the protection of the laws, and not to be treated as a vagabond, was under the necessity of being admitted a member of the tithing where he and his family resided; and in order to obtain this admission, it was necessary for him to maintain a good reputation, because all the members of each tithing being pledges and securities for one another, and the whole tithing sureties to the king for the good behaviour of all its members, they were very cautious in admitting any into their society who were of bad or doubtful characters. Each tithing formed a little state or commonwealth within itself, and chose one of its most respectable members for its head, who was sometimes called the *alderman* of such tithing or free burgh, on account of his age and experience, but most commonly *borseholder*, from the Saxon words *bor*, a security, and *alder*, a head or chief. This magistrate had authority to call together the members of his tithing, to preside in their meetings, and to put their sentences in execution. The members of each tithing, with their tithing-man or borseholder at their head, constituted a court of justice, in which all the little controversies arising within the tithing were determined. If any dispute of great difficulty or importance happened, or if either of the parties was not willing to submit to a sentence given in the tithing-court, the cause was referred or appealed to the next superior court, which was that of the hundred.

BORSET, or **BORSETT**, celebrated for its baths, a place about half a league from Aix-la-Chapelle in Germany. The abbey is a very magnificent structure. It was formerly a monastery, but now serves as a nunnery, the abbess of which is usually a princess of the empire, and lady of Borset. The waters are warm, and of the same nature as those of Aix-la-Chapelle; and they are only used for diseases in which those last mentioned are recommended, and also in dropsical and cedematous cases. The waters are distinguished into the upper and lower springs. The former were found by Dr Simmons to raise the thermometer to 186°, the latter to only 127°.

BORSOD, a circle in the Austrian kingdom of Hungary, the frontiers of which are washed by the rivers Samlor and Torna. It extends over 1332 square miles, or 852,480 acres, comprehends 12 towns, 167 villages, and 19,650 houses, and contains a population of 156,050 souls. Nearly half the land is covered with woods; but the remainder is moderately fertile, and produces good corn, wine, hemp, flax, and some tobacco. The manufactures are chiefly of a domestic kind.

BORYSTHENES. See **BORISTHENES**.

BOS, **JOHN BAPTIST DU**, a celebrated author and member of the French academy, was born at Beauvais in 1670, and finished his studies at the Sorbonne. In 1695 he was named one of the committee for foreign affairs under M. Torez; and he was afterwards charged with some important transactions in England, Germany, Holland, and Italy. On his return to Paris he met with rapid preference, having been made an abbé, and chosen perpetual secretary of the French academy. He was the author of several excellent works, the principal of which are, 1. *Critical Reflections upon Poetry and Painting*, 3 vols. 12mo; 2. *The History of the four Gordians*, confirmed and illustrated by medals; and 3. *A critical History of the establishment of the French Monarchy among the Gauls*, 2 vols. 4to, and 4 vols. 12mo. He died at Paris on the 23d of March 1742.

Borse-
holder
||
Bos.

Bos. See MAMMALIA, *Index*.

Bos, in *Antiquity*, was the name of an ancient Greek silver coin or *didrachmus*, equivalent to two drachms: it was sometimes also struck of gold. This coin was so called from having on it the impression of an ox. It obtained chiefly among the Athenians and Delians. Hence arose the phrase *Bos in lingua*, applied to those who had taken bribes to hold their tongue.

BOSA, a city on the western coast of the island of Sardinia, in a fine valley on the northern bank of the Terno. It is the see of a bishop, and is somewhat subject to malaria, but contains about 4000 inhabitants. Long. 8. 25. 31. E. Lat. 40. 16. 40. N.

BOSCAGE, the same with a grove or thicket.

BOSCAGE, among painters, denotes a landscape representing much wood and trees.

BOSCAN, ALMOGAVAR, JUAN, a Spanish poet of the sixteenth century, born at Barcelona about the year 1500. He was the intimate friend of Garcilasso de Vega, and with him contributed essentially to the improvement of Spanish poetry. He was the first who introduced endecasyllabic verse, and transported into the Castilian tongue the sonnets and other poetical forms consecrated by the usage of the best Italian authors. His poetry is divided into three books, the first of which contains only *redondillas*, while the two others are filled with the pieces which he composed after he adopted his new method, namely, *canciones*, sonnets, tercetts, compositions in the *ottava rima*, and some writings in blank verse. Boscan was tutor to the celebrated Ferdinand de Toledo, duke of Alba, and appears to have died before the year 1543. His works were printed in conjunction with those of his friend Garcilasso, at Medina in 1544, 4to, at Leon in 1549 in 16to, and afterwards at Venice in 1553, 12mo.

BOSCAWEN, EDWARD, a brave British admiral, was the second son of Hugh Lord Viscount Falmouth. Having early entered into the navy, he was, in 1740, captain of the *Shoreham*; and behaved with great intrepidity as a volunteer under Admiral Vernon, at the taking of Porto-Bello. At the siege of Carthage, in March 1741, he had the command of a party of seamen who resolutely attacked and took a battery of fifteen twenty-four pounders, though exposed to the fire of another fort of five guns. Lord Aubrey Beauclerk having been killed at the attack of Boca-Chica, Captain Boscawen succeeded him in the command of the *Prince Frederick* of seventy guns. In May 1742 he returned to England, and married Frances, daughter of William Glanville, Esq.; and the same year he was elected representative for Truro in Cornwall. In 1744 he was made captain of the *Dreadnought* of sixty guns; and soon after he captured the *Medea*, a French man of war commanded by M. Hoquart, the first ship taken in that war. In May 1747 he signaled himself under the admirals Anson and Warren, in an engagement with the French fleet off Cape Finisterre, and was wounded in the shoulder with a musket ball. Here M. Hoquart, who then commanded the *Diamond* of fifty-six guns, again became his prisoner; and all the French ships of war, ten in number, were taken. On the 15th of July he was made rear-admiral of the blue, and commander-in-chief of the sea and land forces employed on an expedition to the East Indies; and on the 4th of November he sailed from St Helen's, with six ships of the line, five frigates, and 2000 soldiers. On the 29th of July 1748 he arrived at St David's, and soon after laid siege to Pondicherry; but the men growing sickly, and the monsoons being expected, the siege was raised, and Mr Boscawen showed himself as much the general as the admiral in his retreat. Soon afterwards he received news of the peace, and Madras was delivered up to him by the French. In April

1750 he arrived at St Helen's in the *Exeter*, and found that in his absence he had been appointed rear-admiral of the white. He was the next year made one of the lords commissioners of the admiralty, and chosen an elder brother of the Trinity-house. In February 1755 he was appointed vice-admiral of the blue. On the 19th of April, sailing in order to intercept a French squadron bound to North America, he fell in with the *Alcide* and *Leys* of sixty-four guns each, which were both taken. On this occasion M. Hoquart became his prisoner for the third time, and he returned to Spithead with his prizes and 1500 prisoners. In 1756 he was appointed vice-admiral of the white, and in 1758 admiral of the blue and commander-in-chief of the expedition to Cape Breton, when, in conjunction with General Amherst, and a body of troops from New England, the important fortress of Louisbourg and the whole island of Cape Breton were taken; services for which he afterwards received the thanks of the House of Commons. In 1759, being appointed to command in the Mediterranean, he arrived at Gibraltar, where hearing that the Toulon fleet, under M. de la Clue, had passed the Straits in order to join that at Brest, he got under sail, and on the 18th of August saw, pursued, and engaged the enemy. His ship, the *Namur* of ninety guns, losing her main-mast, he shifted his flag to the *Newark*; and, after a sharp engagement, took three large ships and burnt two, in Lagos Bay, after which he returned to Spithead with his prizes and 2000 prisoners. On the 8th December 1760 he was appointed general of the marines with a salary of L.3000 per annum, and was also sworn a member of the privy council. He died in 1761.

BOSCOI, or Bosci, in *Ecclesiastical History*, denotes a class or tribe of monks in Palestine, who fed on grass like the beasts of the field. The word is Greek, *βοσχοι*, *graziers*, formed from *βοσκη*, *pasco*. The Boscoi are ranked amongst the number of Adamites, not so much on account of their habit as their food. They took no care about provision; but when eating time came, they went into the fields, each with his knife in his hand, and gathered and ate what they could find.

BOSCOVICH, ROGER JOSEPH, was born on the 18th of May 1711, at Ragusa, a sea-port on the coast of the Adriatic, and capital of a small republic of the same name, then under the protection of the Turks and the Venetians. It does not appear that our author gave any tokens of superior genius till he was sent to learn grammar and philosophy in the schools of the Jesuits, who were at that time the principal teachers in Ragusa, and indeed throughout all Italy. Amongst these shrewd observers his docility and obedience were sufficient to mark him out as a person likely to attain future eminence, and consequently to procure him particular attention. In his fifteenth year, after he had gone through the ordinary course of education, and when it was necessary to decide as to his future pursuits, application was made for his admission into the order; and, for the reasons just mentioned, this was readily complied with, and the subject of the present notice sent to Rome in the year 1725. On his arrival in the Eternal City he entered on his novitiate for admission into the order; but here his studies changed their character and direction, although they were still pursued with diligence. Christian morality, with the rules and constitutions of the order, claimed his attention for two years; after which he was instructed in rhetoric, and became well versed in general literature, particularly Latin poetry, which at that time was very much cultivated.

From the novitiate he was sent to the Roman college to study mathematics and physics; and it was in these sciences that his genius and abilities shone forth so conspicuously, and procured him the admiration of his supe-

Boscoi
Boscovich.

Boscovich. riors. In the course of three years he was able to give private lessons in the mathematics; and he was then exempted from the operation of a law, by which the novices were bound to teach Latin and the belles-lettres for five years before they commenced the study of theology. This exemption was in consequence of his great predilection for the mathematics, of which he was soon afterwards made public professor. For this professorship he was eminently qualified, as, besides a thorough knowledge of all the modern productions in the science, he had acquired a classical severity of demonstration by studying the works of the ancient geometricians; yet he conjoined withal an obliging accommodation of his own habits to the deficiencies of his pupils, and for their benefit composed elementary treatises on arithmetic, algebra, geometry, and trigonometry. But notwithstanding the arduous duties of his situation, he found time to instruct and enlighten more than boys; for about this period he formed some of those refined and original notions which were destined to grow up into the system that afterwards became so celebrated. The animating spirit of discovery and invention led him to consider every portion of physical science; and indeed so versatile and vigorous was his mind, that we should be at a loss to specify any one portion which, within a few years, it did not comprehend, elucidate, and advance. In confirmation of this it will be sufficient to present our readers with an enumeration of the principal subjects to which he turned his attention, and concerning which he published dissertations while he continued in the professorship. These were, the transit of Mercury over the sun, the spots in the sun, the aurora borealis, the construction of spherical trigonometry, the figure of the earth, a new telescope to determine celestial objects, the ancient arguments for the rotundity of the earth, oscillating circles; on infinities and infinitely small quantities, the motion of bodies in unresisting spaces, the aberration of the fixed stars, the inequalities in terrestrial gravity; on astronomy, on the limits of certainty in astronomical observations; on the solid of greatest attraction, the cycloid, the logistic curve lines, the *vires vivæ*, the comets, light, the tides, the rainbow, the calculation of fractions, the centre of gravity, the moon's atmosphere, the law of continuity, lenses and dioptrical telescopes, the objective micrometer, and the divisibility of matter. Some of these are short, but all of them contain curious and valuable matter. It is only by perusing them that we are able to discover the gradual progress of his mind, and to understand the manner in which he arrived at that theory of natural philosophy which is now known by his name.

About this time a taste for philosophical poetry was very prevalent amongst the learned, and some of Boscovich's acquaintances had laboured in it with success. Of these we may mention Father Noceti, who wrote on the rainbow and the aurora borealis, and Benedict Stay, whose poems on the philosophy of Descartes, and on the more modern philosophy, are considered as excellent examples of Latin composition. Boscovich published the works of both with annotations and supplements, in which a splendid fund of information and learning is displayed.

By such undertakings his fame was widely diffused, and he became an object of general admiration. The learned societies of many countries in Europe conferred on him unsolicited honours, and several foreign princes invited him to their courts. His opinions on various subjects of civil architecture, topography, and hydrodynamics, were solicited by Pope Benedict XIV., John V. of Portugal, and others. These applications necessarily required his presence in different states of Europe, where he never failed to enhance his reputation, and often terminated dis-

putes which, but for his judicious interference, might have had disagreeable consequences. Boscovich.

He was employed to correct the maps of the papal dominions, and to measure a degree of the meridian passing through them. In this operation he was assisted by an English jesuit named Christopher Maire. An account of their expedition was printed at Rome and Paris, and is interspersed with some curious anecdotes concerning the opinions which the peasants of the Apennines formed of them, and the operations which they had to perform; but it is chiefly valuable on account of the detail which is given of their observations.

In the year 1757 he was sent to Vienna by the republic of Lucca, to settle some differences which had arisen concerning the draining of a lake, in which the grand duke of Tuscany, the emperor Francis I., and that republic, were concerned; and it was after he had succeeded in the object of his mission to that city that he published there his *Theoria Philosophiæ Naturalis* in 1758.

Another occasion for his mediating powers soon presented itself, and more nearly interested him, as it concerned his native city of Ragusa. The British government having suspected that some ships of war had been fitted out in that port for the service of France, and that its neutrality had thus been infringed, this suspicion alarmed the senate of Ragusa, and required speedy removal, more especially as the consequences might have been extremely prejudicial to their commerce. Boscovich, who had often been successful in similar missions for other powers, appeared to them the fittest person to be intrusted with this. Accordingly, having been nominated by his countrymen, he repaired to London, where he effected the object of his mission with honour to himself and satisfaction to his native state. He visited the Royal Society, which received him with distinguished marks of respect; and he soon afterwards complimented it with an excellent Latin poem on the solar and lunar eclipses. This was in the year 1760. Boscovich was invited by the Royal Society to be of the party of their members about to proceed to America in order to observe the transit of Venus over the sun's disc. But the nature of his embassy, and the necessity of returning home, prevented his accepting the invitation. Soon after his return from this embassy, he was appointed by the senate of Milan to the mathematical chair in the university of Pavia, with the superintendence of the observatory of the royal college of Brera. He continued in this situation for six years, when the empress queen appointed him professor of astronomy and optics in the Palatine schools of Milan, and also requested that he would continue his attention to the observatory. This he expected to prove the most agreeable part of his life. Admired by the learned, beloved by his friends, and having an adequate income, with a sound and vigorous constitution, he promised to himself happy because useful days, in the tranquil cultivation of the sciences. But a cloud long impending now burst over his head, in the edict for the abolition of his order, which took place in the year 1773. No exemption from the edict could be procured; all who held offices were dismissed; and Boscovich sought refuge in the city of Paris. Thither indeed he was invited by Turgot, through whose means he was made one of the directors of optics for the sea service, and received a pension; but it would seem that his situation proved disagreeable to him; nor is this to be wondered at, considering the peculiar circumstances which had induced him to take up his residence in the French capital. He remained there, however, for ten years, on the expiry of which he set out for Bassano, in the republic of Venice, and there published, in five vo-

Boscovich. *lumes quarto*, a collection of the works which he had completed in Paris. The following is a pretty accurate enumeration of their contents: A new instrument for determining the refracting and diverging forces of diaphanous bodies; a demonstration of the falsehood of the Newtonian analogy between light and sound; the algebraic formulæ regarding the foci of lenses, and their applications for calculating the sphericity of those which are to be used in achromatic telescopes; the corrections to be made in ocular lenses, and the error of the sphericity of certain glasses; the causes which hinder the exact union of the solar rays by means of the great burning glasses, and the determination of the loss arising from it; the method of determining the different velocities of light passing through different media by means of two dioptric telescopes, one common, the other of a new kind, containing water between the objective glass and the place of the image; a new kind of objective micrometers; the defects and inutility of a dioptric telescope proposed and made at Paris, which gives two images of the same object, the one direct, the other inverse, with two contrary motions of movable objects; masses floating in the atmosphere, as hail of an extraordinary size, seen on the sun with the telescope, and resembling spots; the astronomical refractions, with various methods for determining them; different methods for determining the orbits of comets and of the new planet, with copious applications of these doctrines to other astronomical subjects, and still more generally to geometry and to the science of calculation; the errors, rectifications, and use of quadrants, sextants, astronomical sectors, the meridian line, telescopes called transit instruments, the meridian, and the parallactic machine; the trigonometrical differential formulæ, which are of so much use in astronomy; the use of the micrometrical rhombus, extended to any oblique position whatsoever; the error arising from refractions in using the astronomical ring for a sun-dial, and the correction to be made; the appearing and the disappearing of Saturn's ring; methods of determining the rotation of the sun by means of the spots; the greatest exactness possible in determining the length of a pendulum oscillating every second of mean time by the comparison of terrestrial and celestial gravity; a compend of astronomy for the use of the marine, containing the elements of the heavenly motions, and of the astronomical instruments, to be explained to a prince in the course of one month; a method for determining the altitudes of the poles with the greatest exactness, by means of a gnomon alone, where other instruments are not to be had; the determination of the illuminated edge of the moon to be observed on the meridian; a method of using the retrograde return of Venus to the same longitude, for determining the less certain elements of her orbit; a method for correcting the elements of a comet, of which the longitude of the node is given, and the inclination of the orbit has been nearly found; another method for the same purpose, and for finding the elliptical orbit, when the parabolic one does not agree with observation; a method for correcting the elements of a planet by three observations; the projection of an orbit inclined in the plane of the ecliptic; the projection of an orbit inclined in any other plane; the calculation of the aberration of the stars, arising from the successive propagation of light; and some beautiful theorems belonging to triangles, which are of great use in astronomy, reduced to the most simple demonstrations.

After the publication of these works, our author quitted Bassano, and went to Rome to visit the companions of his youth. From Rome he proceeded to Milan, where he revised some of his own works, and prepared for publication the two last volumes of Stay's poems. His death

took place on the 13th of February 1787, in the seventy-sixth year of his age.

Besides the different works above mentioned, Boscovich wrote several others on various subjects, as on the project of turning the navigation to Rome from Fiumicino to Maccaresse; on two torrents in the territory of Perugia; on the bulwarks of the river Ponaro; on the river Sidone in the territory of Placentia; on the bulwarks of the Po; on the harbours of Ancona, of Rimini, of Magna Vacca, and Savona; besides some others, almost all of which were printed. For an account of the system developed in the *Theoria Philosophiæ Naturalis*, see the article PHYSICS.

BOSHUANAS, called by some BICHUANAS, or BETJUANAS, a numerous people, or rather race, who occupy an extensive territory in Southern Africa. Their country is bounded on the south by the Cape Colony, on the east by the Caffre territory, on the north by the Makooas, and other tribes bordering on the Portuguese settlement of Mozambique. The western limit is partly unknown, partly composed of extensive deserts.

Down to the commencement of the present century, this people were entirely unknown to Europeans. Mr Barrow, indeed, in his second journey into the country of the Caffres, obtained some notices respecting them. In 1801, while the settlement laboured under a severe scarcity of cattle, two gentlemen belonging to it, Messrs Truffer and Sommerville, set out on an expedition, with the view of procuring a supply. Having passed, first the Great Karroo or Arid Desert, then the Snowy Mountains, and the territory of the rude Bosjesmans, they arrived at an extensive pastoral plain watered by the ample stream of the Orange river, and inhabited by the Koras or Koranas, who appeared considerably superior to any of the other Hottentot tribes. Here they met with a Boshuana, and received from him such accounts as induced them to accompany him to his own country. They soon passed the frontier, and entered on a fertile and finely-watered territory, where, after a few days' journey, they were surprised to find, in the heart of this rude and unknown region of Africa, what might almost be termed a city. The houses and streets of Lattakoo were built and arranged in a manner decidedly superior to any hitherto seen in the southern districts of this great continent. The king, a venerable old man, received them with kindness, and they became to all the natives objects of friendly curiosity. These people appeared to our travellers not only to have made considerable progress in the arts and in civilization, but to live together in a patriarchal simplicity and harmony, which almost realized the fabled pictures of the golden age.

Lord Caledon, then governor of the Cape, on receiving this interesting intelligence, determined to follow out the career of discovery thus opened. He dispatched Dr Cowan and Lieutenant Denovan, with a party of twenty, to endeavour to penetrate through the territory of the newly-discovered people, and if possible to reach the coast at Mozambique and Sofala, by which they would throw important light on a very considerable extent of the geography of Africa. The travellers experienced at Lattakoo the same friendly reception as their precursors; they then arrived at the residence of a chief called Makkrakka, who afforded them a still more cordial welcome. A letter was received from them, dated from the residence of this chief, in about 24. south latitude, in which they described the country as increasing in beauty and fertility, and as watered by a noble river flowing to the westward. Makkrakka sent forward his own brother to recommend them to the Wanketzens, the tribe immediately to the northward. Here they met at first with a reception altogether favourable; but this treacherous people, seeing them thrown

Boshuanas. off their guard, determined upon an attack, for the purpose of seizing all their property. The expedition imprudently separated into three parties, one of which went to bathe, while another remained in charge of the waggons; and a third of the cattle. The natives having attacked successively these three bodies, succeeded too fully in their atrocious design, and entirely cut off the English.

The government at the Cape did not for some time obtain any intelligence respecting this party, and the first rumour of the disaster arrived by way of Mozambique. No official mission has since been dispatched; yet several travellers, animated by liberal curiosity, or the benevolent desire of communicating to the natives the truths of the gospel, have penetrated even deeper into the interior of this region than those now mentioned. Dr Lichtenstein, after an extensive survey of the country of the Caffres, ventured, not without some apprehension, to Lattakoo, but met with a perfectly friendly reception. Being solicited, however, to give aid with fire-arms in a war against Makkrakka, the traveller, unwilling to involve himself in these interior African contests, wisely took the first opportunity of returning, after gaining, however, a good deal of information. In 1813, the Reverend Mr Campbell, at the request of the Missionary Society, and with a view to promote its objects, ventured on an expedition into this territory. Although the dispositions of the people were not altogether such as he could have wished, he had no personal cause of complaint. Lattakoo was found (a change not uncommon in Africa, and consequent upon a schism among its inhabitants) to have been transported about sixty miles from its former situation. It appeared also diminished in size, not containing above 1500 houses and 8000 inhabitants. Although unable to effect any conversions, he obtained, with some difficulty, permission for missionaries to settle here, and a promise of good treatment. In 1820 he returned and found the establishment in a tolerably flourishing state. The missionaries had neat houses and gardens built for their use, with a chapel capable of containing 400 persons, though it was very thinly attended. Mr Campbell penetrated northwards to Mashow, Meribohway, and Kurrechane, towns larger than Lattakoo, and governed by separate chiefs. Mr Burchell afterwards, in the course of an extensive tour through Southern Africa, penetrated beyond Lattakoo, and westward to Bakarrikarri, on the confines of the Great Desert. We have thus, from a succession of intelligent travellers, very satisfactory information respecting this country, and the tribes by which it is inhabited.

The Boshuanas are proved, both by their form and language, to belong to the same race with the Caffres; but their persons are less vigorous, and in the male sex less strikingly handsome; yet many of their females possess a great share of beauty. Although they are not on the whole so fine and manly a race, yet they have made a greater progress in the useful and even ornamental arts. Agriculture is carried on with considerable diligence; though, as is too common in barbarous tribes, its labours are devolved entirely on the female sex, who have the additional task of building the houses and fashioning the furniture and dress. The men, on the other hand, take the entire charge of the cattle, which constitutes their chief wealth. Cultivation is confined to the spaces surrounding their towns, which are built on heights for the purpose of defence; and the cattle are driven out every morning to feed, often at a considerable distance, and brought back at night within the circuit of the inclosures. The habitations are neat and commodious, being encircled with substantial walls of earth or stone; and some parts are moulded into pillars, or other ornamental shapes, and carefully painted. At Kurrechane iron and copper

were smelted in large furnaces of clay; and they had Boshuanas. well constructed vessels of earthenware for holding their grain and stores. The men are dressed chiefly in skins, often prepared with considerable ingenuity; whilst those of wild animals are thrown over their shoulders for ornament. The ladies of rank wear ample mantles, profusely embellished with beads, rings, and various species of ornaments. Makaitshoah, the beautiful wife of the king of Lattakoo, appeared to Dr Lichtenstein, having her robe trimmed with rich furs, a large bundle of cats tails hanging from the left shoulder, and one arm loaded with no less than seventy-two copper rings; the display of which appeared to be an object of peculiar pride.

In regard to their political situation, they have kings who rule with a species of patriarchal authority, and chiefly by means of influence and persuasion. When any affair of great importance is to be decided, a *pectso*, or general assembly of the chiefs and warriors, is summoned. These assemblages are carried on in a peculiar, and even extravagant style. The chiefs on their way indulge in strange gestures and gambols. Before entering on deliberation they commonly join in a song, whilst the principal orator often strikes up a dance. Every speech is prefaced by three tremendous howls or yells, sometimes imitating the cries of animals, while several of the attendants dance in unison. As the debate proceeds, the female citizens form an exterior circle, and by loud cheers or derisive laughter express their sense of the observations made by the speakers.

The distinctions of wealth, and even of rank, are pretty strongly marked in this society; yet they have little influence on the general train of social intercourse. Mattebe, or Mattivi, the chief whom the travellers call king, was seen seated on the ground smoking and exchanging pipes with the most ordinary citizens. He does not interfere in private quarrels, even when they proceed to bloodshed; this is considered to be an affair between individuals. He waits till his arbitration is called for, and then proceeds, often in a very summary manner, executing with his own hand the sentence pronounced.

A considerable degree of internal union and harmony prevails among these tribes. Their manners, making no pretensions to any high refinement, are neither coarse nor boisterous; their general deportment is frank and cordial, and a kind and friendly spirit towards one another seems to prevail. But the intercourse of different states with each other forms a complete scene of violence and rapine. *Commandos*, or forays, to carry off the cattle of their neighbours, and kill all who oppose them, form their most favourite employment. They seem to consider themselves born for this purpose; and the number of cattle which they have carried off, and of men whom they have slain, is through life their highest boast. Dr Lichtenstein even states, that on returning from a successful expedition they celebrate a horrid feast, in which each produces a portion of the flesh of his slaughtered enemy, which he roasts and devours. Towards strangers their behaviour has been generally friendly and hospitable. Mr Campbell's party were indeed astonished, on arriving at one of the towns, to see the warriors rushing forth to meet them, brandishing their battle-axes, painted red, and dressed in the skins of wild beasts; but this soon proved to be only a form of barbarous welcome. After the first ceremony was over, however, they began actively to beg, and even to pilfer tobacco, a European luxury of which they soon became excessively fond. The missionaries have been always well treated, but have never made much progress in their main object. Engrossed by their tumultuary occupations of pasturage and war, this people seem to have a peculiar apathy towards all spiritual and abstract ideas. They

Bosjes-
mans
||
Bosnia.

seem also, from Mr Burchell's observation, to be familiar with all the forms of superstition prevalent among an ignorant people.

In advancing northwards into the interior, the country seems to improve, becoming more populous, while the people are more industrious, and better skilled in the arts. Mashow, beautifully situated on a hill, was estimated to contain 10,000 or 12,000 inhabitants; and it was surrounded by twenty-nine villages, within a circuit of twenty miles of cultivated territory. Kurrechane, still larger and more handsomely built, was supposed to contain 16,000 or 17,000 people.

This country was exposed in 1823 to a most disastrous invasion, from a predatory and ferocious race called the Mantatees, or "wanderers." They were in fact a collected multitude of different Caffre tribes, flying before the attack of the Zoolas, who had formed a dominion on the coast of Natal. The invaders were estimated at 40,000 warriors, almost naked, armed with clubs, spears, and battle-axes, and having their legs adorned with numerous brass rings. They succeeded in sacking Kurrechane; and, after being repulsed from another town, advanced upon Lattakoo, where they spread the most deadly consternation; the inhabitants not being possessed of courage sufficient to enable them to face such a formidable attack. They received, however, the aid of a party of Griqua Hottentots, who had learned from Europeans the use of fire-arms; and after an obstinate conflict turned to flight this immense multitude, and obliged them to retreat within the Caffre territory. (E.)

BOSJESMANS, or BUSHMEN, a race of Hottentots who inhabit the sides and valleys of the Sneeuwberg, or Snowy Mountains, which form the northern boundary of the colony of the Cape of Good Hope. They are rude and savage in the extreme, and, perhaps beyond any other race in existence, deformed and miserable. Their persons present a caricature of that hideous form which characterizes the Hottentot; the hollow back, the large belly, and protruding posteriors, causing them to exhibit nearly the shape of the latter S. Destitute of cultivation, and being allowed to occupy only the most dreary and barren tracts, they find the utmost difficulty in procuring a scanty supply of the most wretched aliments. Wild animals pursued across rugged rocks, roots dug from the earth, and the larvæ of ants and insects, form their only regular resources. To this indeed they add frequent predatory excursions in order to carry off the cattle from the store-farms in the plains below; but this involves them in a severe and unequal contest, since their arrows, though tipped with deadly poison, and shot with surprising dexterity, are not a match for the fire-arms of the colonists. They are hunted down like wild beasts, and, wherever they appear, are shot without the smallest scruple. Mr Barrow met with a young man who had made a journey along part of their territory, and who being asked if he had seen any of them, replied with an air of disappointment, that he had shot only four. From their mode of life, they derive the power of enduring fasting for an extraordinary length of time; though, when they have succeeded in carrying off a sheep or other animal, they devour the flesh without intermission, till it is entirely consumed. Yet they display nothing of that sluggish and gloomy deportment which characterizes the servile Hottentot. They bound with wonderful agility from rock to rock, either in flight or in chase of their prey; and on certain festive occasions, they give way even to an extravagant gaiety; dancing whole days and nights without intermission, especially by moonlight. Even the pictures of animals which they delineate on the rocks are not altogether destitute of spirit or resemblance.

BOSNIA, the farthest north-east province of Turkey in

Europe. It is bounded on the north by Austria, from which it is divided by the rivers Unna and Save; on the east by Semendra and Aladsehaissar; on the south-east by Beldsehterin and Dukagin; on the south by Iscandria and Austria; and on the west by Austria. It extends over 13,000 square miles. The whole province is mountainous, many of the summits reaching to the height of 6000 feet. From the nature of the soil, it is more appropriate for the breeding of cattle than the operations of the plough. The chief kind of cattle reared are sheep in large flocks, some good horses and cows, with here and there a few buffaloes and goats. There are a few mines of copper; and formerly some of gold and silver were worked, especially a very celebrated one at Jlatnizza; but they are now neglected. There are some quarries of good marble; and at Tuzla a very copious and strong spring of salt water, which is converted into culinary salt. The manufactures are of the domestic kind, and upon a small scale, for making leather, cloth, and iron wares. The number of inhabitants, as in all Turkey, is doubtful. The country is thinly peopled; some accounts stating the inhabitants at 850,000, others at no more than 600,000, but all agreeing that the majority are Christians chiefly of the Catholic church.

BOSPHORUS, or BOSPORUS, in *Geography*, a long and narrow channel running in between two lands, or separating two continents, and by which two seas, or a gulf and a sea, communicate with each other. In this sense Bosphorus means a channel or strait, and is synonymous with what the Italians call *faro*, the Latins *fretum*, and the French *pas* or *manche*. The word is Greek, *βοσπορος*, being formed of *βους*, an ox, and *πορος*, passage, probably from an idea that an ox or bullock might swim across.

The name of Bosphorus is chiefly confined to two straits, namely, the Bosphorus of Thraee, commonly called the Strait of Constantinople, or Channel of the Black Sea; and the Cimmerician or Seythian Bosphorus, now known by the name of the Strait of Jenikale. The origin of the name is not disputed; but various mythological legends, some of them absurd enough, were invented to account for its first application.

BOSQUETS, in *Gardening*, groves so called, from *boschetto*, an Italian word which signifies a little wood. They are compartments in gardens formed by branches of trees disposed either regularly in rows, or wildly and irregularly, according to the fancy of the owner. A bosquet is either a plat of ground inclosed with palisades of horn-beam, the middle filled with tall trees, the tops of which form an umbrageous covering; or it consists only of high trees, as horse-chestnut, elm, and the like.

BOSSINEY, a small borough in Cornwall, in the parish of Tintagel and hundred of Lesneweth. It is sometimes called the town of Trevenna. The ruins of a castle near it, according to the local tradition, are said to be those of the palace in which King Arthur was born, and where the ancient dukes of Cornwall resided. The inhabitants amounted in 1801 to 649, in 1811 to 793, and in 1821 to 877.

BOSSO, in Latin Bossus, *Matthew*, distinguished by his virtue and his learning, was born at Verona in 1428. He devoted himself to the ecclesiastical state in 1451, in the congregation of regular canons of St John de Lateran, and afterwards taught divinity at Padua. His orations, his sermons, and his letters, have often been printed. He was also the author of a sort of an apology for Phalaris, and other works; and died at Padua in 1502, aged seventy-five.

BOSSU, RENE LE, born at Paris on the 16th March 1631, studied at Nauterre, and then entered among the regular canons of Sainte-Geneviève in 1649. After hav-

Bosphorus
||
Bossu.

Bossuet. ing professed the humanities in different religious houses for twelve years, he withdrew into retirement, and died on the 14th March 1680. His first publication was *Parallèle des Principes de la Physique d'Aristote et de celle de René Descartes*, which appeared in 1674. He attempted, says Voltaire, to reconcile Aristotle and Descartes; he was not aware that it had become necessary to abandon both. His next work, entitled *Traité du Poème Epique*, was published in 1675, and often reprinted afterwards. The leading doctrine of this treatise is, that the subject should be chosen before the characters, and that the action should be arranged without reference to the personages who are to figure in the scene; a doctrine which led Voltaire to observe that every epic poet who followed the rule of Bossu would be sure of never being read, but that happily it is wholly impossible to follow it. Nevertheless, Boileau, in his *Third Reflexion on Longinus*, pronounces the work of Le Bossu "l'un des meilleurs livres de poétique qui, du consentement de tous les habiles gens, aient été faits en nôtre langue." In abatement of this commendation, however, it may be stated, on the authority of Le Courayer, that Le Bossu had stepped forward as the champion of Boileau against Saint-Sorlin, by whom he had been attacked; that Boileau expressed himself exceedingly grateful for this service; and that a sense of obligation, as much, perhaps, as a sense of justice, may have dictated the commendation bestowed on the work in question.

BOSSUET, JAMES BENIGNE, one of the most illustrious prelates which the church of France, so fruitful in great men, has ever produced, was born at Dijon on the 27th September 1627. He was descended from an ancient and noble family in Burgundy. On the establishment of the parliament of Metz, his father was appointed one of its counsellors. Being destined by his parents for the church, the young Bossuet took the clerical tonsure before he had completed his eighth year. At first he was placed under the care of his uncle, the first president of the parliament of Metz; and he used to relate that, while a mere boy, under his uncle's roof, he read the Old Testament with a relish and delight far exceeding any pleasure he afterwards felt on the perusal of any other work. His uncle afterwards placed him at the college of the Jesuits at Dijon, where he applied himself to his studies with such labour and success that they desired to attach him to themselves; but in 1642 his uncle sent him to Paris to the college of Navarre. Here, under the direction of the celebrated Nicholas Cornet the principal, Bossuet made rapid progress in Greek and philosophy, relieving his studies from time to time by reading the best works of antiquity; but the Scriptures and religious books always occupied a large share of his time. At the age of sixteen he supported his first thesis in a manner which gave indications of his future greatness, and which caused him to be already regarded as a prodigy. An extempore sermon which he shortly afterwards delivered, at the Hotel of Rambouillet, in presence of an assembly partly composed of the most celebrated men of the time, excited general admiration.

He was admitted into the corporation of the college at the age of twenty, on which occasion he chose for the subject of his thesis a comparison between the glory of this world and that which awaits the just in the next. During the delivery of this discourse, the great Condé, who had just dazzled France by the splendour of his victories, suddenly entered the hall, surrounded by a number of his companions in arms. The orator, without interrupting his harangue, immediately addressed himself to the young conqueror, and, in the name of France, paid him a just and appropriate tribute of admiration and praise; but he told him at the

same time how vain and perishable was the glory which he had acquired. Forty years after, Bossuet repeated the same truths over the bier of the princely warrior. During the whole of that long period he had enjoyed his friendship and esteem.

In 1652 Bossuet took the degree of doctor, and received also the order of priesthood. In thus devoting himself to the cause of religion, he exclaimed, "Under thy auspices, O sacred Truth, I will joyfully approach those altars, which are to witness the oath I am about to take; an oath which our ancestors have often heard; that most pleasing and most sacred oath, by which I am to bind myself, even to death, to the holy cause of truth." After passing some time in the retreat at St Lazarus, under the discipline of St. Vincent de Paul, whose friendship he had obtained, he went to Metz, in the cathedral church of which city he had previously obtained the preferment of a canonicate, and where he was successively raised to the rank of archdeacon and dean. He now applied himself wholly to the duties of his ministry, edifying those who surrounded him by the purity of his life, and astonishing them by the splendour of his talents. His first appearance as an author was in 1655, when he published his *Refutation of the Catechism of Paul Ferry*, a Protestant minister highly esteemed for his learning and talents. This work advanced his reputation greatly with his own party, and, it is said, gained him even the respect of the Protestants. The affairs of the cathedral rendering his presence necessary in Paris, he often preached there; and his sermons were so universally applauded, that he was appointed to preach in the chapel of the Louvre before Louis XIV. during the Lent of 1663. His Majesty signified the pleasure he derived from his sermons in a letter which his private secretary wrote by his desire to Bossuet's father.

In 1669 he was nominated to the bishopric of Condom, but being appointed preceptor to the Dauphin the following year, he resigned his see, because he considered his new charge as inconsistent with the duty he owed to his diocese. For the instruction of the Dauphin he composed his work on universal history, which he divided into three parts. The first part is purely chronological; but it has been well observed that it scarcely contains a sentence in which there is not some noun or verb that conveys an image or suggests a sentiment of the noblest kind. The third part, which is historical, contains the most profound reflections on the rise and fall of empires. "But in the second part of it," as one of his biographers observes, "the genius of Bossuet takes its highest flight. He never appears on the stretch of exertion; he is never lost in the mazes of argumentation; but, in a continued strain of sublime eloquence, he displays the truths and proofs of the Christian religion with a grandeur of thought, a magnificence of language, and a force of evidence, which nothing can withstand. A nobler work in support of Christianity has never issued from the press." This work was first published in 1681. Ten years before, he had published his *Exposition of the Doctrine of the Catholic Church in Matters of Controversy*, which was speedily translated into all the living languages of Europe. Pope Innocent XI. formally approved of it by two successive briefs on the 22d November 1678 and the 12th July 1679; and the Gallican clergy in their assembly of 1682 gave it also the seal of their approbation. It has therefore, we believe, been regarded as a correct exposition of the tenets of the Roman Catholic Church.

The publication of the *Exposition* gave rise to the famous conference between Bossuet and M. Claude, one of the ablest divines of the reformed church in France. As a specimen of the argumentative powers of both champions, we shall select a few sentences from that part of

Bossuet.

the conference which relates to the right of private judgment in matters of faith. On the one hand, Bossuet contended for an unconditional submission to the authority of the church; while, on the other, M. Claude only admitted a conditional submission to the decrees of the national assembly of his own, or those of any other church, or, in other words, that a conscientious submission could only be required if the party thought their determinations were conformable to the word of God. "Surely," said Bossuet, "this right of individual examination, which you recognise in each individual, must be accompanied with the highest individual presumption." "That by no means follows," replied M. Claude; "when the synagogue declared that Jesus Christ was not the Messiah promised by the prophets, and condemned him to death, would not an individual who believed him to be the true Christ have judged better than the synagogue? Could you accuse such an individual of *presumptuously* believing that he understood the Scriptures better than all the synagogue?" It is impossible to conceive a more able reply than this. It produced, as it ought, a powerful impression on the audience, and even staggered the great champion of the Catholic church. After a short pause, during which he says he offered up a mental prayer for light and direction from above, he thus addressed M. Claude: "You say that my assertion, that the individual who sets up his private opinion in opposition to that of the whole church must be guilty of intolerable presumption, fixes the charge of equal presumption on those who believed in Jesus Christ in opposition to the sentence of the synagogue which had pronounced him guilty of blasphemy. Most certainly my assertion proves nothing of the kind. When an individual *now* sets up his own private opinion in opposition to that of the whole church, he sets it up against the highest authority on earth, as the earth contains no authority to which an appeal from that authority can be made. But when the synagogue condemned Jesus Christ, there was on earth a much higher authority than the synagogue; to that authority the individual who reprobated the proceedings of the synagogue might appeal. Truth herself *then* visibly existed among men—the Messiah, the eternal Son of God,—He to whom a voice from above had rendered testimony, by proclaiming before the whole people that he was the well-beloved Son of God,—He who restored the dead to life, gave sight to the blind, and did so many miracles, that the Jews themselves confessed no man had done the like before him,—He, the Jesus himself, then existed among men, and was the visible external authority to whom there was a lawful appeal from the synagogue. His authority was infallible. I hear you say that it was a contested authority. I know that it was contested; but, as a Christian, *you* are bound to say that no individual could reasonably or conscientiously contest it. It was not, therefore, presumption—it was duty to disobey the synagogue and believe in Christ. Bring back to me Jesus Christ in person; bring him teaching, preaching, and working miracles—I no longer want the church: but don't take the church from me, unless you give me Jesus Christ in person. You say you have his word. Yes, certainly, we have his holy, adorable word; but what is to be done with those who understand it in a wrong sense? Jesus Christ is not present in person to set them right: they must therefore obey the church. Before Jesus Christ appeared among the Jews, they were bound to obey the synagogue. When the synagogue failed, Jesus Christ came among men to teach them all truth, and they were bound to obey his voice. When he returned to his Father, he left us his church, and we are bound to obey her voice. There is not—no, there is not on earth any visible higher authority to which you can

VOL. V.

appeal from her." This is, no doubt, very ingeniously argued; but, considered as a piece of mere reasoning, it proceeds upon an assumption which cannot be admitted without separate proof, and it evades the case so forcibly put, by introducing the subject of *time*, which, in truth, formed no element in the question at issue. Further, it is evident that, *mutatis mutandis*, the same reasoning might have been employed by the Rabbin of the synagogue, who, on grounds precisely identical, might have argued in favour of the divine authority of the church established by Moses.

Having finished the education of the Dauphin in 1681, the king nominated Bossuet to the bishopric of Meaux, and he entered with zeal upon the duties of his new episcopate. He took a very active part in the general assembly of the church of France held the following year, and drew up the celebrated declaration of 1682 against the attempted encroachments of the see of Rome. Bossuet now directed all the energies of his powerful mind to the most important of all his controversial works, the *History of the Variations of the Protestant Churches*, which was first published in 1688. Gibbon in his younger years was converted to the Roman Catholic faith by perusing this work, retiring for a while, like Chillingworth, to use the expression of Dr Johnson in his *Life of Dryden*, into the bosom of an infallible church. It has been remarked as a singular coincidence, that although no writers were ever more opposed in sentiment than Bossuet and the author of the *Decline and Fall of the Roman Empire*, yet the latter (c. 54) adopts and aggravates the charges made by Bossuet, in his *History of the Variations*, of the alleged Socinian tendency of the principles of the Reformation.

During the last years of his life Bossuet was much occupied in the hopeless scheme of effecting a union between the Roman Catholic and Protestant churches. The negotiation was first carried on with Molanus, who limited his views to a junction between the Roman Catholic and Lutheran churches, a plan which many persons considered by no means impracticable. But Leibnitz, who succeeded Molanus on the part of the Protestants, being desirous of including the whole Protestant churches in the arrangement, the negotiation failed, as might have been expected, after a correspondence of ten years.

It was the fate of Bossuet to be involved in religious controversy during the greater part of his life. He entered the arena at the age of twenty-eight, and during the fifty years which followed, his pen was in constant requisition. He composed with ease, but, like Burke, he laboured hard to improve his writings, and did not cease to alter them till they issued from the press; yet the style of both is as free as if it had been quite spontaneous. Some of Bossuet's principal writings against the Protestants have been mentioned. He was also engaged in controversies with persons of his own communion. That with the amiable Fenelon is the most conspicuous. The mystical speculations of Madame Guyon of Port Royal having found an abettor in the person of the author of *Telemachus*, in a work on the maxims of the saints, Bossuet drew up his *Rélation du Quétisme*, in which the archbishop was attacked with great severity. Fenelon published a reply, in which meekness, simplicity, and grandeur of mind were admirably blended. The writings in this controversy are amongst the finest in French literature; but Quietism being a perishable topic, these writings are now seldom read. In this contest the eagle of Meaux carried off the palm of victory.

Among the writings of Bossuet, his sermons and funeral orations are particularly to be distinguished. Of the latter, the finest is that on the death of Henrietta-Anne, the daughter of our Charles I. and wife of the duke of Orleans. As his funeral orations place him in the first class of orators, so his sermons unquestionably rank him

D

Bossuet
||
Boston.

in the first line of preachers. It has been observed that Bourdaloue and Massillon alone can dispute his pre-eminence. In the opinion of Voltaire, the eloquence of Bossuet stands unrivalled. This great prelate died on the 12th of April 1704, in the 77th year of his age. Massillon and other French writers have eulogised the talents and virtues of Bossuet in terms of the highest admiration; and he is thus noticed by the Reverend Mr Eustace, in his *Classical Tour*: "Bossuet was indeed a great man, and one of those extraordinary minds which, at distant intervals, seem as if deputed from a superior region to enlighten and to astonish mankind. With all the originality of genius, he was free from its eccentricity and intemperance. Sublime, without obscurity—bold, yet accurate—splendid, and yet simple at the same time,—he awes, elevates, and delights his readers, overpowers all resistance, and leads them willing captives to join and to share his triumph. The defects of his style arise from the imperfection of his dialect. And perhaps he could not have given a stronger proof of the energies of his mind than in compelling the French language itself to become the vehicle of sublimity. His works, therefore, are superior to all other controversial writings in his own or any other language." His works were collected and published soon after his decease in twelve volumes quarto. The Benedictines of St Maur published another edition; but a more complete edition, in forty-three volumes octavo, was published in 1815–20. Cardinal de Bausset wrote a history of the life of Bossuet, which was published in four volumes octavo. (A.)

BOSSUPT, a town of the Netherlands, in the province of Brabant. Long. 4. 30. E. Lat. 50. 52. N.

BOST, a very strong town of Persia, and capital of the province of Zablestan. Long. 64. 15. E. Lat. 31. 50. N.

BOSTANGIS, in Turkey, persons employed in the garden of the seraglio, out of whose number are selected those who row in the grand signior's brigantines, when he has a mind to divert himself with fishing, or to take the air upon the canal.

BOSTON, a market-town and borough of the hundred of Skirbeck, in the county of Lincoln, 140 miles from London, on the river Whitham, which divides it into two parts. The river is navigable, and is joined by a canal which connects it with the city of Lincoln. It is in a marshy situation and has a dense atmosphere, but the land surrounding it is highly fertile. The chief object of attention is the church with its lofty tower, 290 feet in height, which having a lanthorn at the top, is a valuable object to ships approaching that flat coast. There is much trade carried on in corn with the metropolis and other parts of the kingdom. The markets are held on Wednesdays and Saturdays. The inhabitants amounted in 1801 to 5926, in 1811 to 8113, and in 1821 to 10,373.

BOSTON, the capital of Massachusetts, is the largest city of New England, and the second in commercial importance in the United States. It is situated at the bottom of Massachusetts Bay, at the mouth of Charles River. It stands principally on a small peninsula of elevated ground, two miles and three quarters in length by one in breadth, and is connected with the continent by an isthmus and by seven bridges. South Boston stands without the peninsula; and including it, the city covers a surface of nearly three square miles. The harbour is capacious, and has a depth of water sufficient to admit the largest ships of war. The anchorage is excellent, the shipping being protected from storms by numerous islands, on several of which are fortifications. With one exception, all the bridges are of wood. That which connects Boston with Cambridge, a minor town, is 3483 feet in length, and is supported by 180 piers. The *western avenue*, as it is called, leading across the bay from the western

part of the city to Roxburgh, is 8000 feet in length, and is formed of solid earth supported on each side by stone walls. It serves the double purpose of a bridge and a dam, by means of which, and a cross dam, two large basins are formed, one of which fills at flood-tide, the other is emptied at ebb-tide; and thus a perpetual water power is created for driving machinery. The wharfs of Boston are spacious, and afford ample accommodation to shipping and storehouses for merchandise. The streets are mostly narrow and irregular, but well paved. The number of dwelling-houses is about 10,000, besides the store-houses and shops, which are numerous. The greater part of the buildings are of brick, but some are of granite and sienite. Many of the dwelling-houses are large and well built. The principal public edifices are the state-house, which stands on the highest part of the city; the county court-house; Faneuil hall; the Massachusetts general hospital; the Faneuil hall market; about forty churches; ten public school houses; two theatres; a house of industry; a house of correction; and a county jail. The city is divided into twelve wards. The municipal government is vested in a mayor, eight aldermen, and a common council of forty-eight members, who are annually chosen by the citizens. There are a great number of well-conducted schools, and a variety of charitable institutions, in Boston. Harvard University, which is the principal literary institution in the vicinity, is situated at Cambridge, three miles distant from the city. The Boston Athenæum has two large buildings, one containing a library of about 24,000 volumes, and the other a picture gallery, with a hall for public lectures, and other rooms for scientific purposes. Among the literary and scientific societies of Boston are the American academy of arts and sciences, the historical society, the Massachusetts medical society, and a mechanics' institution. There are six newspapers published daily, three twice a week, several weekly, and a number of other periodicals, amongst which are the *North American Review* and the *Christian Examiner*. The pursuits of the inhabitants are in a great measure mercantile. They carry on an extensive foreign trade. The shipping owned in 1828 amounted to 161,583 tons. The annual imports amount to about 13,000,000, and the exports to about 9,000,000 dollars. Many varieties of manufactures are carried on here.

Boston was founded in the year 1630, and received its name from a borough so called in England, from which a portion of the inhabitants had emigrated. It was the birth-place of Benjamin Franklin, and here the war of American independence began. Since the year 1783 the population has gone on doubling in about twenty-three years. In 1810 the number of inhabitants amounted to 33,250, and in 1829 to about 60,000. Boston is situated 210 miles north-east of New York. Long. 71. 4. W. Lat. 42. 22. N.

BOSWELL, JAMES, Esq. of Auchinleck, in the county of Ayr, whose life of Dr Samuel Johnson entitles him to a place among those who have contributed to the great stock of intellectual wealth, was the eldest son of Alexander Boswell, styled Lord Auchinleck, one of the judges of the supreme courts of session and judiciary in Scotland. He was born in the year 1740, and, having received the rudiments of his education, partly in his father's house, and partly at Mr Mundell's school in Edinburgh, successively prosecuted his studies at the universities of that city and of Glasgow. He was destined by his father for the Scottish bar; a pursuit with which his own inclinations did not much accord, and instead of which he would gladly have substituted one of greater activity and enterprise. His father's wishes, however, and his own sense of filial duty, prevailed; and, as the study of civil law at one of the foreign universities was then included in the most liberal plan of education for a

James.

Scottish advocate, it was determined that Mr Boswell should repair for that purpose to Utrecht, with a permission, before his return, to make the tour of Europe.

Already, however, those traits of character might be observed which gave a peculiar direction to his after-life. He was very early ambitious of being admitted into the society and friendship of men distinguished by talent and public estimation, more especially those of eminence in the literary world; and his natural urbanity, as well as gaiety of disposition, rendered it no difficult matter to gratify his propensity. While at the university of Glasgow, he had formed a particular intimacy with Mr Temple, the friend of Gray, afterwards vicar of St Gluvias in Cornwall; and he was known to many of the conspicuous characters at that time in Scotland, among others, to Lord Kames, Lord Hailes, Dr Robertson, and Dr Beattie. But the most remarkable acquisition which he made of this kind was his acquaintance with Dr Johnson, which commenced in 1763, and was destined to prove at once the principal era in his own life, and the means of adding not a little to the fame of the philosopher.

Mr Boswell had visited London for the first time in 1760, when he accidentally became acquainted with Derrick, afterwards *King* Derrick, as the master of ceremonies at Bath was then fantastically titled, and by him was initiated into the arcana of London life. In 1763 he proceeded to Utrecht. Having passed a year at that university, he travelled into Germany and Switzerland, was entertained by Voltaire at his castle of Ferney, and conversed with Rousseau in the solitudes of Neufchatel. He continued his route to Italy; but, led by his natural enthusiasm, forsook the common lines of travel, and passed over to Corsica, which, after a contest of more than thirty years, was still struggling for independence with the republic of Genoa. He thus describes his feelings while he approached the island: "As long as I can remember anything, I had heard of the malcontents of Corsica: it was a curious thought that I was just going to see them." Rousseau had given him a letter of introduction to the romantic Paoli; and his tide was suddenly at the full. In the small court of this simple but dignified chieftain he found everything to gratify his taste for the virtuous and sublime in natural character. He became a favourite, too, in his turn; was caressed by the islanders, admitted at all times to the society of their leader, and not only witnessed the movements of their political machinery, but appeared to be himself an actor in the scene. Of his visit to this island he published a narrative on his return to Scotland, entitled *An Account of Corsica, with Memoirs of General Pasquale de Paoli*, printed at Glasgow in 1768. This book was translated into the Dutch, German, French, and Italian languages. He likewise printed, in the following year, a collection of *British Essays in favour of the Brave Corsicans*; and made such attempts as he could to interest the British government in favour of that people, before they were finally crushed by the pressure of the French arms. His acquaintance and friendship with General Paoli were afterwards renewed in London, when that chief, having escaped with difficulty from his native isle, found an asylum in the British dominions.

From Corsica Mr Boswell repaired to Paris; and, returning to Scotland in 1766, he was admitted to the bar. Soon after, he published a pamphlet, under the title of *Essence of the Douglas Cause*; written while that great suit was depending in the Court of Session, with a view to excite the public interest in favour of Mr Douglas. In 1769 he was married to Miss Montgomery, daughter of

David Montgomery, Esq.; an accomplished lady, in whose society he enjoyed every domestic happiness.¹

In the year 1773 Mr Boswell was admitted into the Literary Club, which then met at the Turk's Head in Gerard Street, Soho, and of which Dr Johnson had been an original member. Here he had the pleasure of associating with Burke, Goldsmith, Reynolds, Garrick, and other eminent persons.

Dr Johnson had long projected a tour to the Hebrides; and Mr Boswell at last prevailed upon him, in the course of this year, 1773, to put the plan in execution, and became the companion of his journey from Edinburgh. During this excursion, they saw whatever was most remarkable in the Western Highlands and Isles; and here Mr Boswell was again at large in his natural element. Conscious of the advantages which he enjoyed, and aware of their value, he improved every opportunity of knowledge and remark, and has preserved a faithful record of all. His feelings were like those which Dante ascribes to the pilgrim, who, having paid his vows,

"Long gazes on the holy fane, and thinks
How he shall paint it when he reaches home."

Both travellers gave to the world an account of this tour. Mr Boswell's *Journal* was published in 1785. In the course of this work he has given a simple and very interesting narrative of some minute circumstances attending the escape of Prince Charles Edward after the battle of Culloden, collected from the information of persons on the spot, and privy to his concealment; particularly from the celebrated Flora Macdonald, whom they visited at Kingsburgh, in Sky, and from Malcolm Macleod, who had been the faithful and intelligent companion of the Wanderer's flight.

Lord Auchinleck died in 1782; and, a few years after (1786), Mr Boswell, giving up his law pursuits at Edinburgh, removed with his family to London, towards which, as a great emporium of literature and theatre of varied life, his inclinations had always tended. He had recently before been called to the English bar. He did not, however, prosecute the profession, but gave himself up to his natural bent for society and letters. After Dr Johnson's death, in 1784, he was occupied for several years in collecting and arranging, with indefatigable diligence, the materials for a narrative, which he had long projected, of that eminent man's life.²

Besides the works which have been already mentioned, he was the author of two Letters addressed to the People of Scotland; being his only productions of a political character. In the first of these, which was published in 1784, he appeared as an advocate for the new administration, then recently formed. The second Letter, written in 1785, was a strenuous appeal against a measure brought forward under the sanction of the same ministry, for effecting a reform in the Court of Session in Scotland, by reducing the number of the Judges.

Mr Boswell died on the 19th June 1795. In his private character, he was loved by his friends, as well as a favourite in the circles of social life; and, if his attachments were often suddenly formed, they were not less durable on this account. Whatever he has written is favourable to virtue; and, during a course of living which naturally dissipates the mind, his moral principles remained entire, and his religious faith unshaken. "Few men," says his friend Sir William Forbes, in a letter published in his *Life of Dr Beattie*, "possessed a stronger sense of piety, or more fervent devotion—perhaps not always sufficient to regulate his imagination, or direct his conduct, yet still genuine,

¹ He had a family by her of two sons and three daughters. Mrs Boswell died in 1790.

² *Life of Samuel Johnson*, LL.D. 2 vols. 4to. London, 1791.

Boswell,
James.

and founded both in his understanding and his heart." His talents would probably have been rated higher if they had not been obscured by certain eccentricities of character; yet his writings bear sufficient testimony to his natural abilities, and to the delicacy as well as aptness of his intellectual touch. He has described himself as being of a temperament inclined to melancholy; but in society he was remarkable for the gaiety of his disposition, and his life was full of activity and stir. To be distinguished was his ruling passion, and he indulged it freely. He sought those whom the world, on whatever account, held in honour; and he was desirous of being known as one with whom they assorted, and who possessed their friendship. He was fond of his pedigree and family connections, and he aspired after literary fame. While some of these propensities have been common to the great and good in every age, others, it must be confessed, are more frequently harboured than avowed. Mr Boswell adopted the latter and more unusual course.¹ He fairly owned his passion, and, if not thus secured from attack, had all those advantages, at least, which are gained by meeting an enemy in the field. But, in reality, he has dealt so openly, and with such candour, on every occasion which touches himself as well as others, that he wins not only our forgiveness, but our affection, and maintains, by ingenuousness and complete truth of character, a kind of superiority over any person who should feel desirous of assailing him. Nor was evidence of a substantial sort wanting to show the independence of his mind. For, however attached to individuals of extensive influence, and however ambitious of exalted patronage, he was neither an instrument of party nor a server of the time. What he gave in attention he received back in kindness; and, while he associated with the learned and the philosophical, he contributed his share to the general stock of enjoyment. Of Dr Johnson's sincere attachment to him there are many and unequivocal proofs in their correspondence.

But it is not on account of his private character, or of a certain domestic celebrity which he enjoyed during his life, that he is to be distinguished in a work of this kind. We commemorate him as an author, and particularly as a writer of biography. Here he is almost an inventor; he has at least carried this species of composition to a degree of accuracy and detail formerly unattempted. Other writers, as the Abbé de Sade in his *Memoirs of Petrarch*, and Mason in his *Life of Gray*, had conducted the course of their narratives partly by means of original letters. But Mr Boswell has, more than any preceding biographer, made use of all the varied means by which such a history admits of being dramatized. He paints the whole man, presents the incidents of his life in their actual order of succession, and preserves him as it were entire; fulfilling in the history of the moral, what Bacon has assigned to philosophy as her genuine work in that of the natural world, faithfully to return its accents and reflect its image, not to add any thing of her own, but to iterate only and repeat.

The plan of keeping a Miscellaneous Journal had been recommended to him by Dr Johnson on their first acquaintance; and he appears very early to have followed it, as far as writing down what was remarkable in the conversation of those whom he admired. From his frequent allusions to the discourses of Selden, commonly called his *Table Talk*, as preserved by Lilward, it is probable that he had the example of that work in his view; and by long use he acquired a great facility in this process. Of his first publication, containing an account of Corsica, the

Journal of his residence with General Paoli is by far the most interesting part. It is a sketch remarkable for life and natural colouring; and is one of those productions which, though enhanced by their occasion, do not depend on this circumstance alone for the attraction which they possess. In his *Journal of a Tour to the Hebrides*, he pushed to a still greater extent, and even beyond its just limits, his favourite style of writing. Carried away by his natural enthusiasm, and delighting "to pour out all himself, like old Montaigne," he indulged in a more ample and unqualified disclosure, both of his own sentiments and of the opinions of others, than is consistent with a salutary prudence, or necessary for the purposes of instruction. Of this he himself became sensible on cooler reflection, and not only acknowledged it with candour, but, in his subsequent and more laboured compositions, profited by the general opinion, and imposed a greater restraint upon his pen.

For the task of writing Johnson's life he was in many respects peculiarly qualified. He had lived in habits of intimacy with the sage for a period of twenty years, had early conceived the plan of such a work, and received from Johnson himself, to whom his intention was known, many particulars of his early life and personal history. As the writer was thus furnished for his undertaking, so there has seldom been a more fertile or interesting subject for the biographer. Johnson was not a mere scholar, "deep versed in books, and shallow in himself," nor was he one of those unprofitable misers who hoard without expending. He was a general and a minute observer, and, while he possessed in a degree seldom equalled "the strenuous use of profitable thought," his talent for communicating knowledge was more remarkable even than the large capacity of his mind, or the accumulation of his learning.

According to Baker's character of King James, in that passage which Mr Boswell happily prefixed to his *Journal*, "he was of an admirable pregnancy of wit, and that pregnancy much improved by continual study from his childhood, by which he had gotten such a promptness in expressing his mind, that his extemporal speeches were little inferior to his premeditated writings. Many, no doubt, had read as much, and perhaps more than he, but scarce ever any concocted his reading into judgment as he did." Johnson's conversation, accordingly, is the matter and substance of the book; and, as the philosopher did not, in the midst of his studies, forget to cultivate his friends, nor gave up the advantages and comfort of society, there was in his discourse a range and diversity of subject not often found in combination with classical knowledge and habits of profound thinking. Nor does this work exhibit a series merely of witty and sententious sayings: it is interspersed alike with miscellaneous narrative and criticism; and, which constitutes its principal feature, it contains a mass of opinions on subjects of a more common nature, where the powers of reasoning and illustration are applied to familiar topics, and the ordinary occurrences of life. Valuable as a deposit of literary anecdote, it is still more so as a collection of ethical discourses, to which its popular form gives a singular currency and effect; so that there are few books extant where the religious and social duties, as well as the love of science, in its largest acceptation, are impressed more agreeably, or with greater force, upon the mind.

Among the many circumstances which have conspired to heighten our interest in this narrative, is the exhibition which it affords of illustrious characters in different

Boswell,
James.

¹ "Egotism and vanity," says he, in his Letter published in 1785, "are the indigenous plants of my mind: they distinguish it. I may prune their luxuriance, but I must not entirely clear it of them: for then I should be no longer as I am and perhaps there might be something not so good."

Boswell,
James.

walks of life. The period was distinguished by an unusual measure of genius and talent; and we are not only introduced to the closet of the philosopher, but carried with him also into assemblages of the brilliant and the wise, with whom he associated. The tone of this society, moreover, is highly pleasing; and in harmony with our best principles and feelings; in which respect it is impossible to avoid contrasting it with those more boasted Parisian societies during the same period, which were supposed to be the centre of French literature and wit, as they are displayed to us by some of the chief actors in that scene.¹ Mr Boswell's work has not yet, indeed, acquired all its interest; the period is still too recent; but, to estimate its value in after-times, we have only to consider what we ourselves should have gained if such a volume had been preserved to us from the rolls of ancient life.

In the great attainments of a biographer, which are the truth and minuteness of his relation, Mr Boswell has been eminently successful. If, in this species of writing, an author is exempted from the formality, as well as comprehensive research, necessary in the higher classes of historical composition, it is well known that he has his peculiar difficulties to encounter; difficulties, too, which are the greatest where, by his intimate knowledge of the subject, he is best qualified for the task of writing. Nor does the partiality to which he is himself exposed constitute his only danger; since he is no less apt to be led away by the expectation of gratifying his readers. We are fond of seeing the picture of character completed according to our fancy, and, whatever be the feeling which has commenced, we are impatient of any interruption to its train. In the case of those whom we respect and love, the disappointment is doubly ungrateful; we dislike being told of their frailties, because we are unwilling to believe that they were fail. But such is not the colour nor the tissue of human characters; and the artist who would represent them truly, must do perpetual violence to his inclination. The fidelity of Mr Boswell's portrait may be ascribed, in a great measure, to the form and method of his composition. Had he given us only the results of his observation, the effort at impartiality could scarcely have been preserved; but he has presented us with the whole materials as he found them, and allows us to work them up for ourselves.

In the other distinguishing quality of a biographical work, namely, the minuteness of its information, he is so little deficient, that his observance of this requisite has been converted into an accusation against him. And it is certain, as already observed, that, in his early productions particularly, he left some room for such a charge; and that, while his veracity and candour were unimpeached, his prudence was not on all occasions equally conspicuous. Yet it must be remembered that the great use of biography is to bring instruction home; to give us examples, not of individual actions and conduct merely, but of that conduct as displayed in the common paths of life. The history of nations is too often a species of heroic romance. Its lessons are, at all events, of a different nature from those now in question; and its moral is far too remote to answer the necessities of individuals. General precepts, again, when delivered without the aid of story, commonly fail to produce their effect, either because they fail to excite attention, or because the power of applying them to particular cases remains as difficult as before. Nor do works of fiction, however excellent, and even where the scene is laid as it were at home, and the characters are those of a private station, leave any very permanent impressions on the mind. They do not carry with them a sufficient pre-

sence and authority; for the writer's first object is not to instruct, but to please; and, above all, they want that great requisite, truth, for which, in the time of need, all others are abandoned and forgotten. A manual of instruction for human conduct, which, instead of being couched in general maxims, or calculated for situations of unusual occurrence, should descend to particular cases, and to the ordinary emergencies of private life, would certainly be one of the most valuable presents which philosophy could offer to the bulk of mankind. Biography makes the nearest approach towards the compilation of such a code; and, as a commentary on moral duties, it is, when faithfully executed, invaluable. But it is so in proportion only to the closeness of the resemblance and the exactness of the detail. Minuteness, therefore, is the characteristic and soul of biographical writing, if its proper uses are considered.

That such a plan of delineation may be carried to excess, indeed, is undeniable. He who is accustomed to set down whatever he sees and hears, may become indiscriminate in his choice, and forget the value of his store in the pleasure of collecting it. To ascertain the just medium in this respect, is one of the many things for which rules are ineffectual. A sound judgment alone can determine the limits. As to the license of publication, the biographer is under one common restraint with authors of every class. He violates the due boundary if he introduces into his work what is injurious to virtue, or if he discloses, for the purposes of general information merely, any thing which may probably affect the interests or wound the minds of the living. When that period has arrived which secures against dangers of the latter description, even individual characters become, to a certain extent, the property of mankind at large, and may be employed as a vehicle for instruction, if exhibited with fidelity. On this score Mr Boswell, notwithstanding his natural promptness and want of reserve, has, in his latest and principal work at least, given little ground for animadversion. His habitual quickness of feeling and liveliness of fancy appear to have been corrected, where others were concerned, by his love of justice, and a general benevolence of mind.

With regard to his style of writing, a progressive improvement in it may be discovered through his different productions. It is in general well suited to his matter, is animated and easy where he is himself the narrator, and bears evident marks of being true to the original, where, as commonly happens, he is a reporter merely. On the whole, whatever blemishes may be found in it as a literary composition, his *Life of Johnson* is a very valuable work, fraught with information at once useful and pleasing. There are few books which present learning in a more attractive form; and few where the seeds of knowledge are scattered more profusely.

See the *Gentleman's Magazine*; Chalmers's edition of the *Biographical Dictionary*, 1812; and the writings of Mr Boswell, *passim*. (o. o.)

BOSWORTH-MARKET, a market-town in the hundred of Sparkenhoe, in the county of Leicester, 107 miles from London. Near it is the celebrated field of the battle between Richard III. and Henry VII., then Duke of Richmond, by which the crown of England was transferred to the latter. The market is held on a Wednesday. The inhabitants amounted in 1801 to 791, in 1811 to 954, and in 1821 to 1117.

BOTAL or BOTALLI, LEONARD, physician to the duke of Alençon, and to Henry III., was born at Asti in Piedmont. He published several books in physic and surgery; and the best edition of his works is that of Leyden, in 1660, octavo, published by Van Hoorne.

Boswell,
James

BOTANY.

General
Observations.

LINNÆUS divides all natural objects into three grand classes, which he calls kingdoms; and the sciences which treat of these are zoology, botany, and mineralogy. Botany, with which we are to be occupied in this place, enables us to distinguish, arrange, and name all plants or vegetables.

Some years ago, Baron Humboldt made a calculation as to the probable number of the different species of plants existing on the face of our globe. Of late, however, owing to the many novelties that have reached us from Brazil and the East Indies, it has been supposed that his estimate is much under the truth. At least sixty or seventy thousand, described or undescribed, are scattered through different collections, and every day brings to light additional species; so that at present the probable number of vegetable productions may not be too highly estimated at nearly a hundred thousand. To obtain a knowledge of every one of these individually, and without relation to any other, would be a Herculean task, for which the utmost extension of human life might not be sufficient, and which, though procured, could not be imparted to others. The study would thus be selfish, and the labours of a lifetime useless. Valuable medical properties might be observed in some one vegetable; but posterity would, in all probability, find similar properties in another plant, much sooner than re-discover that formerly known. Thus many plants whose medical qualities were highly esteemed by our ancestors, are now entirely unknown to us as possessing such. To remedy these evils, means must be resorted to for the classifying or arranging of vegetables. If we divide them into trees, shrubs, herbaceous, biennial, and annual, we shall have five divisions; so that supposing an equal number to each, we shall have only to look into one of those sections for what we are in quest of. Again, each of these may be subdivided according to the height to which the plant grows, the colour of its flower, or its capability of bearing an esculent fruit. But this is one of the rudest systems, and, though used in the earliest state of the science, was soon found to be subject to great variation, and to want the necessary precision. Other more philosophical divisions were afterwards adopted, to which, and the steps requisite for the knowledge of them, we intend to devote this article.

The necessity of a classification being once admitted, resemblances between individuals, not before observed, could not long escape the attention. Thus the affinities *inter se* of the different species of pine, of the ash, of the lime, of the strawberry, or of the rose, must soon have been admitted; and in framing a system, care would be taken to place these by the side of the allied species, whether in appearance or in qualities. This is what is termed arranging plants according to their species. It would likewise be soon observed that small groups of these species had more affinity between themselves than with other groups;—a general idea would thus be attached to each of these, which would now form a genus;—and when these genera were placed one after the other according to some property or resemblance real or fancied, we should have the arrangement of plants by their genera. Whether, then, we proceed by making grand primary cuts or divisions among all the known vegetables, and then proceed to subdivide these until we arrive at genera and species; or commence by the grouping of species and genera, and mount upwards, we shall attain the means of more readily distinguishing and naming plants, and consequently of imparting to others the result of our observations on their properties and uses.

The *cui bono* in botany is a question that has often been

asked by those who conceive that mere classification is the ultimate object of botany; but, from what has already been said, we trust it will be seen that classification is only the necessary consequence of a wish to impart our ideas to others. It is a universal language, without which the observations of one can be of no use to another, but by which the instructed can unfold to each other, at the remotest parts of the earth, what species or genera of plants have been discovered to possess remarkable properties. "The standing objection to botany," says the eloquent author of the *Natural History of Selbourne*, "has always been, that it is a pursuit that amuses the fancy and exercises the memory, without improving the mind, or advancing any real knowledge; and where the science is carried no farther than a mere systematic classification, the charge is but too true. But the botanist who is desirous of wiping off this aspersion should be by no means content with a mere list of names; he should study plants philosophically,—should investigate the laws of vegetation,—should examine the powers and virtues of efficacious herbs,—should promote their cultivation, and graft the gardener, the planter, and the husbandman, on the phytologist: not that system is by any means to be thrown aside,—without system, the field of nature would be a pathless wilderness; but system should be subservient to, not the main object of, our pursuit." Nor ought an objection to be urged against the pursuit of those parts of botany from which hitherto no immediate use has been derived. From the highest organized plant to the lowest, all form a chain, in which a link lost or broken disconnects the whole, and to which the recent addition of new links, in the shape of new species, has tended much to the increase of our knowledge. What anatomist has not derived delight from the examination of the eye of a fly; and what botanist has not obtained information from the meanest weed! But it is even important to attend to the lowest class of vegetables. The lichens furnish many valuable dyes; the algæ afford food or medicine; and we are all so alarmed at the poisonous effects of many fungi, that scarcely above two or three species are eaten in this country, whereas, if attention were paid to their botanical character, several far superior in flavour to the common mushrooms might be made use of with perfect safety.

The definition of botany here adopted, though easily understood and perfectly correct, is sometimes of little value to the practical man. Between mineralogy and the two other sciences of zoology and botany we believe there can be little confusion; but between zoology and botany, in the subjects belonging to both of which the living principle seems equally to exist, not only are there great points of resemblance, but instances occur in which it is nearly impossible for the eye to determine whether what we see belongs to the one or to the other kingdom.

The distinction made by Linnæus between plants and animals consisted principally in the power of motion in the latter. Many animals have, however, now been discovered, which seem to be unable to remove themselves from the spot on which they first made their appearance; and, on the other hand, there are many plants, as the duckweed (*Lemna*), ball-conferva (*Conferva agagropila*), and others, which, if they have roots, do not send them into the earth, but float about as if in search of food; and our distinguished countryman Mr Brown, whose philosophical observations all must respect, has within these few years demonstrated that the component particles or molecules

General
Observations.

General
Observations.

of all matter whatever, whether organized or not, when suspended in a fluid, and viewed with a suitable microscope, are found to be in motion without any visible agency. Perhaps the true differences are to be looked for in sensation and an intestinal canal in the animal kingdom, into which the food is collected; whilst plants are endowed only with irritability, and receive the food through many canals or mouths. But this, although it were universally acknowledged, is of little service, as confusion is only likely to arise in the case of the smallest and least organized, and where the correct knowledge of the anatomical structure is attended with almost insuperable difficulties. In many zoophytes, or lower tribes of marine animals, the external horny or calcareous covering so resembles a plant in its mode of ramification, as to cause doubts which are not easily removed; and there consequently exist many natural objects to this day that are claimed by both the zoologist and botanist. This similarity, combined with the motion to be observed in all molecules, has, we think, given rise to the singular delusion under which many celebrated men abroad have for some years past laboured, when they assert that the minute aquatic algæ were animalcules in the first stages of their being, but which afterwards took root and became plants. A rudimentary plant may have often been mistaken for an infusory animal, and may have even been described as such; and although there be no absolute practical character of almost any use to enable us to distinguish the two, yet we consider their identity as a mere matter of speculation, that has never been proved, and which is not borne out by any analogy derived from what are more organized, and on which observations would be less subject to error.

Subservient to the actual classification and determination of plants, and consequently forming branches of the science of botany, are, *1st*, Organography, or the anatomy of plants, or the knowledge of the structure of their parts or organs; *2d*, Physiology, or the knowledge of the functions of these parts; *3d*, Pathology, or the derangements to which these functions are exposed; *4th*, Terminology or Glossology, or a knowledge of the terms employed to designate the parts or organs; *5th*, Phytography, or the art of describing plants, so that every species may be distinguished and recognised; and, *lastly*, Taxonomy, or the art of combining all these in such a way as to produce a systematic arrangement or classification.

What are usually called *medical botany*, *agricultural botany*, and *economical botany*, do not belong to the science of botany, as one might at first suppose from the names, but form respectively mere connecting links between botany and *materia medica*, as well as agriculture and domestic economy. They exhibit the relation existing between vegetables and the arts, and point out the uses to which different plants are applied. But although they therefore must fall under other subjects in this work, a certain knowledge of their general relation must be of considerable use to the botanist, inasmuch as it may enable him to frame a classification that will bring nearer together plants of similar properties and virtues, as well as of a similar form and structure.

In the same way, botanical geography is not a branch of botany. This exhibits the relation between vegetables and the soil on which they grow, and the climate in which they delight, or, in other words, the physical causes, and the laws of their distribution over the surface of our globe. This will form a part of Physical Geography.

Horticulture or gardening, or the art of cultivating plants so as to improve their beauty or ameliorate their qualities, is dependent on vegetable pathology; but it has long been considered as separate from botany, and will be treated of as a distinct science.

The above six branches of botany are so intimately con-

nected, that it is difficult to discuss one without encroaching on the others. As, however, these are discussed in other parts of this work, we shall here confine ourselves, as much as the nature of the subject will admit, to the three latter;—Glossology, Phytography, and Taxonomy; under which last will be found a short historical sketch of the science.

Glossology.
Pl. CXII.

I.—GLOSSOLOGY.

Glossology, or, as Linnæus called it, Terminology, gives us, as has already been stated, the knowledge of the terms employed, or furnishes definitions of the names applied to the different parts or organs. The structure of these constitutes organography or anatomy. An account of the organs themselves belongs also, strictly speaking, to the same branch of the subject; but as a mere explanation of terms might prove useless and uninteresting, without understanding to what these terms are to be applied, we shall here exclude the elementary organs, or those which compose the others, and blend the two together; and thus, by explaining the organs and their successive developments, endeavour to lay a foundation, without which a knowledge of the natural system of classification cannot be acquired. Under *VEGETABLE ANATOMY*, these organs are treated of as subservient to physiology. Here we shall consider them as connected with classification. And as in this article we do not intend to insert a catalogue or description of plants, so we shall pass over many terms that are not essential to a general view of the subject.

The organs of plants not elementary have been divided by De Candolle into the fundamental and reproductive. The former are such as are essential to the nutrition of the plant, while the latter are mere modifications of these. We shall therefore first proceed to the

FUNDAMENTAL ORGANS.

These consist of roots, stems, and leaves.

Roots (Radices).

We shall suppose a seed put into the ground under favourable circumstances. The inherent vital principle common to both plants and animals begins to operate; and a development takes place downwards as well as upwards. The descending portion is termed the Root; and by it plants are fixed to the earth, and nutriment absorbed. In some aquatic plants no root whatever is perceptible. But in such apparent aberrations from what seems a general rule of nature, it may be presumed by analogy that roots do exist even when they have not been observed; in confirmation of which it may be stated, that many plants to which roots were long denied, have actually possessed them in some parts of their existence, and are capable of deriving nourishment either from the earth, water, or air, although in a few the foliaceous portions of the plant are such as almost to preclude the necessity of their having any.

There are several characters which distinguish the root from the stem. The principal are the absence of leaves, of pith even in those plants in which it is abundant in the stem, and of spiral vessels.

A root usually consists of three parts: the *neck (collum)*, or line of separation from the stem; the *body* or middle portion of the root; and the attenuated fibrous portion, or little roots through which the nourishment is principally derived. Keeping this in view, a root of the simplest kind is, *1st*, what is termed *conical*, or the principal or tap root as it is sometimes called; this tapers downwards, emitting fibres from various parts of its surface, as in the carrot (Plate CXII. fig. 1): *2d*, when the conical root is attenuated

Glossology. towards the neck, as well as below, it is called *fusiform* (fig. 2), as the radish: 3d, when swollen out extremely in the upper part, and suddenly attenuated below, it is *napiform* (fig. 3), as in the turnip: 4th, when the fusiform root is as it were cut off suddenly, it is termed *abrupt* (*præmorsus*) (fig. 4), as in the devil's bit scabious: 5th, *fibrous* when the body of the root is so reduced as not to be apparent, and nothing is seen but simple or branched fibres proceeding from the neck: 6th, when these fibres swell out slightly in the middle, the root is called *fasciculated* (fig. 5): 7th, when the fibrous root bears, either at its neck, or here and there attached to its fibres, one or more tubers, fleshy, and containing much starchy feculent matter, it has been often called *tuberous*, but ought really to be termed *tuberiferous*, such tubers serving for the nourishment of the plant; when two of such tubers are placed together, as in some species of orchis, they are said to be *didymous* (fig. 6); and when these again are divided up to the middle into diverging lobes, they are *didymous palmate* (fig. 7). Some give the name of tuberous roots to any root whatever that contains swellings or tubercles on some part of its length; but in neither sense ought tubers to be classed among roots. In the one they are more properly short, fleshy, subterranean stems, containing usually eyes or buds, from which new plants arise; and in the other they have a very different structure, and are generally termed, 8th, *granulated* roots. These exhibit a collection of small tubercles with eyes fit for the reproduction of the plant, without being enveloped by cellular tissue filled with starchy fecule, and thus differ essentially from the tuberiferous. In the same predicament with the tuberiferous is the *bulbous* root (fig. 8). This consists of a thin, flat tubercle, called by cultivators of hyacinths the crown, from the lower part of which proceeds a fibrous root, while above there is a bulb or peculiar kind of bud, formed of a number of scales (as in the lily), or coats (as in the onion), closely applied to each other; such may rather be termed *bulbiferous* roots, the bulb being equivalent to a leaf-bud, and the crown to a stem.

With regard to direction, there are only two requiring any notice. The one is *contorted*, when bent upwards and downwards in a zig-zag manner, as may be seen in the bistort; the other is a *creeping* root. The usual direction for a root is towards the centre of the earth, but it sometimes happens that one or all of its parts deviate at a right angle from this, and proceed laterally parallel to the surface. When this takes place it is said to be *creeping*. Roots of this kind are said to be among the greatest enemies the agriculturist has to encounter; but they are in a measure harmless, much confusion prevailing between them and subterranean branches; and we would therefore warn the young botanist not to fall into the error. Indeed the number of creeping roots is much less than has been generally thought; for in most cases these will be found to be true branches springing off from the stem above the neck of the root, but afterwards developed under ground, and even from different points throwing out radical fibres. Among these is the couchgrass (*Triticum repens*), and the potato, the fibrous parts of which bearing the tubers are now ascertained to be branches, as might indeed have been long ago suspected, from the care found necessary by cultivators to be paid to the heaping up of the earth on the lower part of the stem, so as to increase the number of these branches, and render the crop more abundant. In some plants, as in *Vicia amphicarpa*, such branches or false roots bear pods under ground.

Stems (Caules).

Reverting to the germination of a seed, that part which springs upwards is the stem: it is therefore the interme-

diate body between the root and the leaves. When the first state of germination is observed, the rising stem is surrounded by rudimentary leaves. It is thus similar to those gems or leaf-buds that are afterwards observed in the axillæ of all leaves, and which afterwards become branches; and it may therefore be stated in general terms, that all stems are produced by the successive developments of leaf-buds.

When the stem of a plant arising from a seed is evident, the plant is termed *caulescent*; and when not apparent, or scarcely so, the plants have received the names of *acaules* or *subacaules*. These last terms, however, must not be taken in a rigorous sense; for although a stem be sometimes extremely short, or even entirely under ground, it always exists. We may refer here to *Gentiana acaulis*, *Carduus acaulis*, and many others, said to have no stem, but which really have one so surrounded by the bases of the leaves, as to be overlooked until they be planted in a more genial soil, when the stem becomes more visible. We have already stated that the crown of what is called a bulbous root is the real stem;—and in the genus *Cyclamen*, what is usually considered a tuber is an actual stem, from the base of which fibrous roots are protruded, and from the top, leaves and flowers.

It often happens that the stem, instead of ascending, stretches, either wholly or in part, under ground or on the surface, emitting here and there roots from below, and branches or leaves which rise upwards. Such a stem is called a *rhizoma* (fig. 9), or, if it do not emit fibres, a *cor-mus*. Most of what Linnæus improperly described as creeping roots are of the former description: of these each rising branch may easily be separated, and becomes a new individual. The jointed roots or scaly roots of botanists are also subterranean stems; for the knots and scales are the rudiments of buds and leaves, which no true root possesses. Sometimes a plant pushes out horizontally long stems of a peculiar nature, emitting only from the extremity roots and leaf-buds, as in the strawberry. Such stems are termed *stolones* or *runners*.

Branches as well as stems arise from leaf-buds. Every leaf or modification of a leaf possesses these in their axillæ, or the angle formed by the leaf and the branch; and therefore all leafy stems must likewise be branched, and without any limit to the ramification, unless the leaf-bud has met with injury, or in peculiar circumstances has not been called into action. As leaf-buds are axillary, so branches are not elongated, strictly speaking, by means of leaf-buds, but by a prolongation of the axis of the original leaf-bud from which it arose. This distinction is, however, very subtle and unnecessary; for the terminal scaly bud, though only the undeveloped portion of a leaf-bud, is so similar to regular leaf-buds in the external as well as internal structure, that they cannot be distinguished but by their position. De Candolle indeed calls them all leaf-buds, and we ourselves feel inclined to admit the idea of a terminal leaf-bud; but, while we do so, we must add, that from the terminal being really only a portion of an axillary one, it must be viewed as a modification of the axillary; and therefore, although appearances be sometimes against us, we must again repeat that all leaf-buds are axillary. Spurious leaf-buds, or *gemmæ* as they are called, sometimes capable of producing branches and leaves, or even new individuals, are frequently scattered irregularly on the stem or branches, as, for example, on the elm, where they are abundant; but these must not be confounded with true leaf-buds. The leaf-buds, the development of which depends on the rise of the sap, have the outer or lower scales or leaves first expanded; and this same law ought to hold with regard also to their successive development. And such is the case in some trees. But the extremities of the branches

Glossology. being almost always more herbaceous than below, and more liable to be acted upon by atmospherical heat, the buds towards the summits are usually first evolved, and then, proceeding gradually downwards, those below them, so that the lowest buds are the last expanded.

The summit of branches or stems is usually green, soft, and herbaceous; and when the primary stems do not rise above the surface, but only the tender branches, that plant is termed *herbaceous*, in opposition to those with a *perennial* stem. An herbaceous stem generally dies down to the ground every year. A perennial stem may be *succulent* or *fleshy*, *woody*, *shrubby*, or *somewhat shrubby*; but these terms bear their own meaning. Linnæus devised for expressing the duration of plants four very simple marks, which have been adopted by nearly all botanists. These are, $\odot$, to denote annual; $\mathfrak{z}$, biennial; and $\mathfrak{z}$, perennial; while $\frac{1}{2}$ indicates a shrub or tree. De Candolle, however, has somewhat changed these and added others. He adopts four principal signs, $\odot$, $\mathfrak{z}$, $\mathfrak{z}$, and $\cup$. The first relates to a plant called monocarpic, or which flowers and fructifies only once; the second denotes a rhizocarpic plant, which has herbaceous stems that die down to the ground every year; the third applies to a caulocarpic one, whose stems are straight and perennial; and the last marks a climbing plant. The first, third, and fourth of these, being indefinite, are divisible into several others: Thus, $\odot$, shows the life of the plant is only for one year; $\odot$, for two years; $\odot$, that it is many years before it flowers, but after which it dies. Again, $\mathfrak{z}$, indicates a suffruticose plant, or one that though shrubby does not elevate itself more than a foot or two; $\mathfrak{z}$, denotes a shrub of from two to ten feet high, in which the branches arise from the base of the stem; $\mathfrak{z}$, marks a small tree of from ten to twenty-five feet high, and whose trunk is without branches at the base; and $\mathfrak{z}$, is a decided tree upwards of twenty-five feet. As to the symbol for climbing, $\cup$ marks a plant that climbs to the right, and $\cup$ one that climbs to the left. To these the same botanist has added $\triangle$, to point out an evergreen.¹

On examining the trunk or branch of an ash or oak tree, we perceive in the centre a mass of spongy cellular tissue,² called *pith*. Around this, and inside of the wood, are placed a series of spiral vessels and ducts, constituting the *medullary sheath*. This communicates on the one side with the pith, and on the other with the medullary rays, leaf-buds, and veins of the leaves. Next we find the *wood*, consisting of concentric layers, one of which is formed every year. These layers are composed of cellular tissue, woody fibre, and ducts, and are traversed by the medullary rays composed of cellular tissue, and connecting the centre with the circumference. The fully formed or central layers are called the *heart-wood*, and the exterior the *alburnum*. The *bark* surrounds the wood. This may be seen to have the same number of concentric layers as the wood, but of these the hardest or most fully formed is exterior, and the youngest interior. The *liber* is that portion of the bark which is successively formed next the wood. Each concentric layer, whether of wood or bark, consists of two strata, the one of woody fibre and ducts, the other

Glossology. of cellular tissue, of which the latter in the wood is interior, and in the bark exterior; so that wood and bark may be viewed as similarly constituted of woody fibre and pith; which last, however, in the bark, is on the outside. Betwixt the liber and alburnum is formed in spring a viscid secretion called *cambium*. The matter which causes such plants to increase in diameter has been found by experiment to descend; but the investigation of this subject belongs more to vegetable anatomy and physiology. Suffice it to say, that such an appearance as we have above described takes place in a very great proportion of vegetables; and from the circumstance of their receiving the annual increase between the outside of the old wood and inside of the old bark, some botanists have termed such plants *Exogenous* (*Exogenæ*). There are other plants, however, in which no such distinctions exist, and where the stem is formed of bundles of ducts and spiral vessels interspersed through a cellular tissue; and this is surrounded by a stratum of cellular tissue and woody fibre, different from bark, inasmuch as it cannot be separated from the stem itself. Such plants have their diameter increased by the addition of central vascular tissue and ducts, and are therefore called *Endogenous* (*Endogenæ*). Both *Exogenæ* and *Endogenæ* containing spiral vessels, are called *vascular*, in opposition to another division of vegetables, the *cellular* (*cellulares*), in which they do not exist; but as these plants do not spring from seeds, we shall pass them over at present.

Occasionally, projections from the medullary sheath reach the circumference of the stem and branches, forming what are called *nodi*, to which are attached leaves and leaf-buds; and the spaces between these *nodi* are called *internodia*. The tuber of the potato seems to be a collection of these *nodi* and leaf-buds (there called eyes), the leaves being abortive from the tubers being formed under ground.

The stem peculiar to the grasses and other allied tribes is termed a *culm* (*culmus*). This is simple, or rarely branched, generally hollow within or fistulose, and separated at intervals by knots or partitions, from which issue the leaves.

The stem may be *simple* or *branched*, and with the branches may be *cylindrical* or *conical*; *round* (*teres*) or *angled*; *smooth* (*lævis*), *furrowed*, *glabrous* (free from any processes), or *rough*, or *pubescent*, or *hairy*. These terms, bearing the same signification in botany as in common language, need no definition. Among *Endogenous* plants, from the abortion of leaf-buds, the stems are usually cylindrical and unbranched; while, from the leaf-buds being almost always developed in the *Exogenæ*, the stems are generally branched and conical.

Belonging to the stem we may take notice of two processes. The one is a *spine* (*spina*), which always arises from what was a leaf-bud; it is therefore a kind of branch, and must not be confounded with the other process, or *prickle* (*aculeus*), which does not spring from leaf-buds, and is a mere dilatation of the cellular portion of the bark.

Leaves (Folia).

Leaves are those expansions which issue laterally from the stem and branches of plants. They take their origin

¹ The Linnæan character $\mathfrak{z}$ has been employed by De Candolle to mark a flower or a plant that bears stamens and no pistils; and, to correspond with it, he has recommended the adoption of $\mathfrak{z}$ for a plant with pistilla and no stamens; $\mathfrak{z}$, according to him, designates a plant which has flowers containing both.

² To save our readers the trouble of referring at every step to the article on VEGETABLE ANATOMY, we shall give here an explanation of the principal elementary organs:

1. *Cellular tissue*, or *parenchyma*, is composed of transparent vesicles, variously cohering with each other.
2. *Woody fibre* is a tissue consisting of elongated tubes, similar to the vesicles of cellular tissue, and is therefore often also called *elongated cellular tissue*.
3. *Spiral vessels* are formed of elastic tissue, twisted spirally into the form of a cylinder, and capable of being unrolled. To these alone the name vessels (*vasa*) ought to be given; and hence they are always to be found in the vascular tissue of plants properly so called.
4. *Ducts* are elongated, transparent tubes, composed of a tissue that is not capable of unrolling.

Glossology. from the bark, and are always to be observed, either in a rudimentary or perfect state, immediately below the leaf-buds. They are originally continuous with the stem and nodi, but afterwards, from a cause that does not appear to be yet well understood, an articulation more or less complete takes place, when the leaf falls off. Very few instances occur where there are no leaves on the stem, as in the genera *Orobanchæ*, *Lathræa*, and *Cuscuta*, and even then there are rudimentary leaves in the shape of scales or tubercles.

Position of the leaves. The first thing we have to attend to is the position of the leaves. Those situated near the root are often larger, and of a different shape, from those higher up the stem; and the former are termed *radical*, the latter *cauline* leaves. We usually observe, that as these approach the extremity of the branches which bear the flower, they decrease much in size, assume a different form and colour, and are termed *floral leaves* or *bractæas*. Of these we shall afterwards have occasion to speak, when we come to the inflorescence of plants.

When the stem or branch is cut through, several leaves are sometimes found in the same horizontal plane. When only two are observed, and these opposite to each other, they are usually said to be *opposite*. It has, however, been lately proposed to term opposite those only, the bases of whose petioles are connected either by stipules or otherwise, reserving to the others the appellation of *pseudo-opposite*; but this distinction has been hitherto adopted by almost no systematic writer. When more than two are in the same plane, they are said to be in *whorls*, or *verticillate*; but, strictly speaking, such are of very rare occurrence; *Hippuris* and *Myriophyllum* may however serve as examples. But it is improper to apply this term to the leaves of the genus *Galium*, in which the two opposite leaves alone bear axillary leaf-buds, the others being mere foliaceous stipules.

When the branch is cut through horizontally, and only one leaf appears in the section, the leaves were said by Linnæus to be *scattered* (*sparsa*), or *alternate*, with little discrimination. More modern botanists have, however, observed that these are primarily arranged regularly; but afterwards so many disturbing causes occur as to render their true disposition scarcely perceptible. By true alternate leaves ought to be understood those only which are placed on two sides of the branch, in such a way that the third leaf is under the first, and the fourth under the second; and when such are close together they are said to be *distichous*. But leaves are usually placed in simple spirals, in such a way that the sixth is under the first, the seventh under the second, and so on. There are also instances where the spiral is formed of more than five leaves, and hence there may be double, triple, quintuple, or sextuple spirals. The practice, however, still prevails of calling all such alternate in which the spiral is not very evident.

Of these two systems the type of the verticillate is the opposite, while that of the spiral is the alternate; and cases even happen where the one of these seems almost to pass into the other. Thus, in Exogenous plants, although the leaves may be opposite to each other on the lower part of the plant, they often assume the spiral direction above; and, in the Endogenæ, although the lower leaves be in a spiral, the upper ones are sometimes verticillate. This induced Desfontaines to institute a close analysis, by which he discovered a remarkable relation between the structure of the stem, the number of cotyledons, and the disposition of the leaves, from which we are now enabled to derive a general law, that in all Dicotyledonous or Exogenous vegetables, the leaves are primarily opposite, or verticillate, but may become alternate, or form a spiral, according to the mode of growth of the plant; and that in all the Monocotyledonous, or Endogenæ, the reverse happens, the

leaves being primarily alternate, or in a spiral, but afterwards subject to be more or less exactly opposite. Thus, in the position of the leaves we have an auxiliary to enable us to determine to which of these two great classes of vegetables a plant belongs.

Some botanists add to the above *fascicled* leaves (*folia fasciculata*); but these are combinations of which both systems are susceptible. Thus, in *Aspalathus*, where the three leaflets appear to arise from one point, this is a deception caused by the shortness of the petiole. Another case commonly quoted is, when the leaf becomes abortive at the same time that a very short branch furnished with leaves appears from the leaf-bud. Thus, in the barberry, the thorn is the rudiment of the real leaf; and what we call leaves are new leaves placed close together on a very short branch, and belonging to the leaf-bud. In the pine tribe the sheath is the rudiment of the leaf; while the two, three, or five leaves within it are the first leaves of an abortive branch. The cedar exhibits and explains this very easily; for in the early part of spring, the leaves are fasciculated; but in summer, when the leaf-buds or axillary branches have time to elongate, the leaves become alternate.

A leaf consists of the petiole, the lamina or limb, and a Petiole. pair of stipules; but sometimes only one of these three parts can be observed. The *petiole* is that which connects the lamina with the stem, and through it the bundles of ducts and spiral vessels pass before they branch out in the limb. Its form is usually cylindrical or slightly channelled above; but it sometimes happens that it is flattened, and presents on each side a foliaceous appendage, when it is said to be margined, as in *Dionæa muscipula* (fig. 41, b). This margin is frequently contracted at regular intervals; and from each contraction in a compound leaf springs a leaflet. We often find, however, that the leaflets are abortive, in which case the petiole may easily be mistaken for the lamina; and this is indeed what is called by some a lomentaceous leaf. But more commonly a terminal leaflet remains, although the others be abortive, as we see in the orange tree; and to distinguish the two kinds we must be much guided by analogy. This confusion is however of little consequence; for as we may regard the longitudinal nerve of the leaf as a prolongation of the petiole, the limb or lamina itself may be viewed as a margined petiole.

The fibres that pass through the petiole, and which in Exogenous plants arise from the medullary sheath, and in the Endogenous from the bundles of vascular tissue, sometimes in the former class, instead of being united from the base into a compact bundle, as more commonly happens, spring side by side from various points more or less round the branch. The base of the petiole is thus plane, and is *amplexicaul* or *semi-amplexicaul*, or perhaps even *sheathing* (*vaginans*). Before the fibres enter the lamina, however, they tend to one point, so that the upper portion does not differ from a common petiole with a rounded base. This expansion of the base of the petiole is to be seen in a remarkable manner in the upper leaves of *Bupleurum perfoliatum* and some others, where it has all the appearance of a foliaceous limb.

Towards the summit of the stems of the *Umbellifera*, the lamina and the cylindrical part of the petiole frequently disappear, nothing remaining but the sheathing base. In *Lathyrus Nissolia* this happens to all the leaves, and there the sheathing base becomes more dilated than usual. The affinity derived from other considerations between *Pyrola* and *Monotropa* shows that the scales of the latter are petiolar sheaths, and in the *Orobanchæ* tribe they must be viewed in the same manner.

It happens sometimes, especially when the lamina is not developed, that the petiole, without being sheathing

Glossology. at the base, expands throughout its whole length, and takes a state intermediate between foliaceous and petiolar. **Pl. CXII.** This has received the name of *phyllodium*; as in many species of *Acacia* from New Holland, some of which when young present a slender petiole and a bipinnate leaf, but afterwards lose their leaflets by the dilatation of the petiole.

Sometimes the petiole is elongated beyond the lamina, or perhaps in compound leaves the terminal leaflet may have no lamina but only the midrib, while the petiole or midrib retains its usual cylindrical figure, becomes very long, twists spirally, and then constitutes a tendril (*cirrhus*) (fig. 37, a). In others, though rarely, the leaves are abortive, and the petiole remains straight and cylindrical. In some plants with compound leaves, as in *Astragalus Tragacantha*, the terminal leaflet becomes abortive or is changed into a spine, when the petiole is said to be spinescent.

Lamina. The *lamina* of the leaf next claims our attention. This is an expansion of the parenchyma of the petiole, and commences where the bundles of vascular tissue that traverse the petiole begin to diverge from each other and form what are called the veins of the leaf. The divergence of these fibres, says De Candolle, is in two different ways. They either separate, making with the base or its prolongation an angle properly so called, and most frequently an acute one, when the leaves may be said to be *angulinerved*; or they form on the base or its prolongation a curvature, when the leaves may be termed *curvinerved*. The former structure is essential to the Exogenæ, the latter to the Endogenæ. Among those, the nerves of which form an angle, there are four forms.

1. Leaves *penninerved* (fig. 14), where the petiole is prolonged into one longitudinal nerve, which on both sides sets out lateral nerves, as in the Spanish chestnut. In a linear leaf these lateral nerves must be all equal in length; in an elliptic, oval; or orbicular leaf, those about the middle must be longer than those at the base or summit of the leaf; in an ovate one, the longer nerves are below the middle; in an obovate leaf, above the middle. When the lower pair or two lower pairs of nerves are much larger than the others, and almost the size of the midrib, as in the Jerusalem artichoke, the leaves are said to be *triplinerved* or *quintuplinerved*.

2. Leaves *palminerved* (fig. 10), where several nerves diverge all at once from the base of the leaf.

3. Leaves *peltinerved* (fig. 11), where several nerves radiate from the apex of the petiole in a plane different from the direction of the petiole. It results from this disposition that the lamina does not appear at first to be a prolongation of the petiole, but rather a disc placed at its summit. It is evident, when the point of attachment is near the margin of the lamina, that we should have almost a palminerved leaf; indeed in some plants these two forms occur promiscuously.

4. Leaves *pedalinerved*, where the central nerve is very short, but setting off on both sides two strong diverging lateral nerves, which, instead of being branched alike on both sides, present almost no lateral nerves on the outer side; whilst, in the inside, secondary nerves spring out almost parallel to each other. This form is of rare occurrence, but may be seen in some passion-flowers.

The curvinerved leaves may either have their nerves converging or diverging; but these require little illustration.

In Exogenous plants the veins branch in various directions, anastomosing, and forming a kind of net-work. In Endogenous plants they are nearly parallel to each other, being connected by single transverse unbranched veins.

To this the *Coniferae* and *Cycadææ* form perhaps the only exceptions: these have the stems of the Exogenous, but the same arrangement of the veins as in the Endogenæ. **Pl. CXII.**

The veins of some leaves are capable of producing from their extremities *gemmae* similar to those we have described as occurring on the stem and branches. These *gemmae* usually arise from the margin; but as the vein must be open, or have a stoma, as it is anatomically called, at the point of insertion; and as such stomata, though frequent on the under side, have been rarely observed on the upper surface; so the *gemmae* are seldom or never produced on the upper side.

A leaf is either simple or compound. It is *simple* when its lamina is entire (*folium integrum*), or when, if separated into several divisions, these segments are not articulated with the petiole. The position and ramification of the nerves have great influence in determining the shape of the leaf. Of those that are entire, the simplest of all forms is the *linear* (fig. 12), where the margins are parallel. By the central position of such a one being slightly dilated, we have an *oblong*; when more dilated, an *elliptical* leaf (fig. 13); and when much so, an *orbicular* one. When the dilatation is below the middle, we have an *ovate* (fig. 14); when above the middle, an *obovate*¹ leaf (fig. 15). When the oblong tapers gradually into a point at the apex, it becomes *lanceolate* (fig. 16). If a leaf be very narrow, and taper upwards from its base, it is *subulate* (fig. 17); and when long, narrow, stiff, and sharp, it is said to be *acicular* or *setaceous* (fig. 18); when narrow and very slender, it is *filiform*. When an elliptical leaf tapers much below, so as to be narrow at the base, and broad and rounded at the summit, it becomes *spathulate* (fig. 19); and when narrow at the base, and truncated or somewhat squared off at the top, it is *cuneiform*. Such are the principal forms. When almost any of these are produced at the base, so as to have two lobes on each side of the petiole, they are said to be *cordate* or *heart-shaped* (fig. 20 and 21) when the lobes are rounded; *sagittate* (fig. 22) when acute and scarcely diverging; and *hastate* (fig. 23) when acute and diverging much outwards. When an orbicular leaf becomes cordate at the base, it is called *reniform* (fig. 24).

Leaves, or rather the lamina of leaves, are either sharp-pointed or *acute*, *pungent*, *mucronate*, or *acuminated*, or they are *blunt* (*folia obtusa*), (fig. 15, 24,); when such a leaf has a small sinus at the apex, it is *retuse* (fig. 25); when the sinus is deeper, as if a piece had been cut out, it is *emarginate* (fig. 26); and when still more so, *obcordate*; till by degrees we have *bifid*, two-lobed (*folia biloba*) (fig. 27), and *bipartite*. What is called the appendage (fig. 41, a) in *Dionæa muscipula* is a two-lobed lamina. From the gradual transition of one form into another, botanists might long ago have learned the little importance to be attached to any individual shape; unhappily, however, for science, species have too often been multiplied on such weak grounds. In studying the phytographical department, we would recommend, that either in describing, or endeavouring to understand a description, each form should be taken with a considerable latitude of meaning, and as subject to vary into the others on either side.

A divided leaf may be *cleft* (*folia trifida, quadrifida, &c.*), or, if the divisions be deeper, it is *lobed* (*folia triloba, &c.*), and, when deeply cut, partite (*folia tripartita, &c.*); but when the divisions are deep and unequal, the leaf is *lacinated* (fig. 28). When a leaf is rounded at both extremities, but contracted in the middle, it is *panduriform* (fig. 29) or violin-shaped; and when there are more than

¹ The terms *ovate* and *obovate*, although generally adopted, are incorrect; they ought to be *oval* and *oboval*. A truly ovate leaf refers to thickness as well as surface. It has indeed the shape of an egg, and oval is the longitudinal section of such.

Glossology. one contraction on each side, as in the oak, it is *sinuated* (fig. 30). When a leaf is divided laterally into lobes more or less deep, it is *pinnatifid* (fig. 31); when these lobes are very narrow and nearly parallel, it is *pectinate*; when the lateral lobes are acute and recurved, it is *runcinate* (fig. 32); when the terminal lobe of a pinnatifid leaf is round and larger than the others, the leaf is *lyrate* (fig. 33); when a leaf is so deeply divided laterally that the lobes are only connected at their base, it is *pinnatipartite*; and when the lobes are completely isolated, it is *pinnatisect* (fig. 34). Linnæus, as well as many modern botanists of eminence, called the last *pinnate*, and referred it to a compound leaf; but the transition from the entire leaf to the pinnatisect shows distinctly that the latter is but a simple leaf, of which all the parenchyma has not been developed.

A divided leaf may have its lobes again divided, when it is said to be *bi* or *tri-pinnatifid*, &c.

A compound leaf is when the lamina is articulated with the petiole. It is either digitate or pinnate. Leaves are *digitate* (fig. 35) when all the leaflets start from the same point at the apex of the petiole, as in the lupines; in the orange there is but one leaflet; in other plants three, four, or more. Leaves are *pinnate* when the leaflets spring out laterally from the common petiole, and are *oppositely* (fig. 36) or *alternately* pinnate, according as these leaflets are opposite to or alternate with each other; and are *imparipinnate* (fig. 36) or *paripinnate* when there is, or is not, a terminal leaflet. When there is but one, two, or three pairs of leaflets, the leaf is said to be *unijugate* (*folium unijugum*), *bijugate*, *trijugate* (fig. 37), &c. A *decompounded* leaf is where the common petiole is divided into secondary petioles, each of which bears a foliole or leaflet. Of these, when the secondary petioles all spring from the apex of the common petiole, the leaf is *digitato-pinnate*; or when there are only two secondary petioles, *conjugato-pinnate* (fig. 38). When each of the secondary petioles bears only one pair of leaflets, the leaf is *bigeminate* (fig. 39); and when the secondary petioles spring out as leaflets do in a pinnate leaf, but are themselves pinnate, the leaf is *bipinnate* (fig. 40). Decompounded leaves may be again divided, when they are called *supradecompounded* (*folia supradecomposita*).

The margin of the divisions of a simple or compound leaf is variously modified. It may be *very entire* (*integerrimum*) or *crenulate*, when furnished with little projecting points; or *dentated*, when the margin presents small radiating acute teeth, that neither incline to the bottom nor to the apex of the leaf (fig. 21); or *serrated* (fig. 14), when the teeth are inclined; or *thorny*, when the teeth are narrow, stiff, and sharp (as in the holly); or *ciliated*, when there is a series of hairs along the edge, like a person's eye-lashes.

With regard to the *expansion*, *surface*, *pubescence*, *consistence*, *form* (we do not mean by this the superficial shape, but the shape as a mass, of which the other is but a section), and *colour*, it is unnecessary to say any thing, having restricted ourselves to a more general view of the subject.

Leaves unite very easily either with each other or with the stem. When two have their margins close together at the time of their development, they often unite quite accidentally; but there are some plants in which such a union is not accidental, but constant. In the honeysuckle a transition may be observed from the leaves perfectly distinct, to those that are joined by their bases. The genus *Bauhinia* presents many instances of leaves being united by their edges: a palminerved leaf may thus be viewed as composed of several penninerved leaves soldered partly together. When leaves unite to the stem they are termed *decurent*; and this may be either caused by the middle

nerve coalescing with the stem, as in the floral leaves of *Glossology* the lime tree, or by the adherence merely of a prolongation of the parenchyma of the leaf. Pl. CXII.

Some botanists speak of an *appendiculate* leaf, in which there ought to be an extraneous body attached to it; but the more the structure of the different parts is studied, the fewer instances are to be recorded. Thus a cirrus or tendril is usually an abortive leaflet, or petiole, or stipule. The supposed appendage of *Dionæa muscipula* (fig. 41, *a*) is the real lamina of the leaf, while the supposed leaf is the petiole (fig. 41, *b*). The pitcher of *Nepenthes* (fig. 42, *a*) is also now regarded as the leaf; and the lower portion (fig. 42, *c*) the petiole, which is partly margined. This plant, however, is scarcely yet completely understood; probably the lid (fig. 42, *b*) to the pitcher alone is the limb of the leaf; while the petiole at first consisting (as in the lower leaves (fig. 43, 44) that arise from the plumule on germination) of a mere pitcher, afterwards elongates (fig. 42, *c*, *a*) into a margined portion, a cirrus, and a pitcher. In *Sarracenia*, said also to have a pitcher-shaped leaf, the petiole forms a hollow sheath with the lamina or lid at its apex.

Stipules (fig. 37, *b*) are those small foliaceous organs sometimes situated on each side at the base of the petiole. They never occur in the *Endogenæ*, nor in any *Exogenous* plants that have sheathing petioles, and are rarely found in genera with opposite leaves. Their presence or absence seems to be eminently connected with the general symmetry of plants, for they exist or are wanting in all of the same family. They have frequently the same structure, and are often transformed into leaves; even leaf-buds have been observed in the axils of some of them, so that they may be viewed as rudimentary leaves. Stipules sometimes change into spines; but the spines in *Acacia* are not stipules, but prolongations of a swelling of the stem under the leaf, which serves it as a kind of support. This is evident from there being frequently real stipules independent of the spines; but usually, when the spines are formed, the stipules above them are abortive. Stipules seem occasionally to change into tendrils, and this is the most probable explanation of the lateral tendrils of the gourd and cucumber tribe. They are in general smaller than the leaves; but in *Lathyrus aphaca* they are remarkably large, while the leaves are entirely abortive. Those at the base of the same petiole are not always alike; one of them even in some plants becoming abortive, while the other persists. Stipules that are situated between the petiole and the branch are *intrapetiolar*; and, in the case of opposite leaves, when they are between the two opposite petioles, they are *interpetiolar*, or *intrafoliaceous*. Stipules sometimes unite together, and when so, if they form a sheath round the stem, they are called *ochrea*; and if the union take place between the petiole and the stem they are termed *intra-axillary*. They also often adhere to the petiole by their margins, and then one must use the greatest caution not to confound with them the cellular appendages of the petiole itself.

Leaves arise on the young shoots, or already exist *Vernation* more or less developed when the shoot begins to appear. At this period the external leaves frequently take the appearance of scales, and serve as a protection to the others. The compact mode in which the young leaves are arranged before expansion is called the *vernation* or *gemination*, and is determined by different causes, viz. their position on the stem and mode of adherence, the disposition of the principal nerves, and the different degrees of separation or union of the parts. All the appearances resulting from these may be reduced to three classes: 1st, They are folded or rolled longitudinally on the midrib, which remains straight; or, 2d, they are folded or curved,

Glossology. so that the summit touches the base; or, 3d, they are neither curved nor folded in a sensible degree.

Pl. CXII. The usual state of Exogenous plants is to have the leaves so folded that the two parts of the lamina on each side the midrib are applied to each other by their upper surface; but this is much modified by other circumstances. Thus, when two penninerved leaves are strictly opposite, and another pair at right angles to these, they are only half folded, in such a way as to inclose the inner pair; and such a veneration is termed *opposite* (fig. 45). When less decidedly opposite, one of the sides of each leaf is exterior and the other interior (fig. 46), and then the veneration is *half-equitant* (*semiamplexa*); and when the leaves are alternate or spiral, they are each of them folded by themselves, and placed side by side, when it is called *conduplicate* (fig. 47.) Palminerved leaves being considered as composed of several penninerved ones united by their margins for some part of their length, each of the divisions has a tendency to be folded, exhibiting a *plicate* veneration (fig. 48). The leaflets of palmate leaves present of course the same disposition. Some penninerved leaves, although folded together, have the margins rolled outwards, as in the rosemary, and the veneration is *revolute* (fig. 49); or they may be rolled in, as in the water-lily, and it is *involute* (fig. 50). These latter peculiarities are very rare among the Exogenæ, but common among the Endogenæ. When the young leaves are so narrow that they are not folded, but cover each other without any apparent order, they are said to be *imbricated*. Such plants as have a petiole that embraces the stem for some length (which chiefly happens among the Endogenæ) present a slightly different disposition. Here most of the leaves are reduced to a dilated petiole, and are simply curved and imbricated the one over the other, as in the coats of what are erroneously called bulbous roots (fig. 8); but there are other plants with a sheathing petiole, that show an inclination to a longitudinally-folded leaf (as in the *Iris*) as much as if they had a midrib, and the veneration is *equitant* (fig. 51); so called because, as they are alternate, each of them rides upon or embraces by its two margins the two margins of the leaf that follows it. Another disposition, but almost peculiar to the Endogenæ, is the *convolute* (fig. 52), as in the scitamineæ, where the limb is rolled round one of its margins on an axis. The veneration is termed *replicate* when the leaf is so folded that the upper part is applied to the lower, as in the aconite; and *circinal* when, instead of being folded, it is rolled in such a way that the apex serves as an axis; which last curious structure may be observed in the genus *Drosera*, and in the *Cycadææ*.

CELLULAR PLANTS.

The observations hitherto made relate almost exclusively to Vascular plants, the terms relating to the external forms of which alone can be applied also to the Cellular vegetables; so that, before proceeding to the reproductive organs, we may devote a few lines to such as come under the latter denomination. And here we must draw a line between such as are furnished with ducts in addition to mere cellular tissue, and those in which we find an entire homogeneity of structure; and, for the sake of distinction, we shall call the former *ductulosæ*, and the latter *educulosæ*.

Ductulosæ.

All belonging to this section, on account of the presence of ducts, and in some instances apparently of stems, more than one author of eminence has classed with vascular plants; but there are no spiral vessels present, and although it is often difficult to distinguish between spiral

vessels and ducts, we prefer to make the characters of the Glossology. two great classes of vegetables depend on the presence or absence of the former, rather than of the latter; the more so because we feel convinced, that, with the aid of spiral vessels, and not without them, can true seeds be produced. As ducts are always to be observed in roots, even in the most fibrous, so there is a presumption that true roots exist in all the ductulosæ. As, however, no spiral vessels occur above the root, there can be no collum or line of separation between stem and root, and therefore the whole plant may be viewed as one uniform body, every section presenting the same structure. On account of the appearance of stems, the ductulosæ may be said to have an axis.

1. The *Equisetaceæ* must first be noticed. These have Equise- little or no resemblance to the other ductulosæ, and almost tacææ. as little to the vascular plants. Their nearest affinity is perhaps with the genus *Casuarina* (one of the Exogenæ). Their veneration is straight. They have no true leaves, but a furrowed fistular stem, in which, under the cuticle or external membranous coating, so much silex is deposited as to render some of the species of great use in polishing furniture and other household utensils. The stem is moreover articulated, separating at the joints, each articulation being surrounded by a prolongation of the joint below it in the shape of a membranous toothed sheath; the number of the teeth, if not combined, corresponding with the number of the furrows on the stem. The stem is either simple, or has branches articulated like the stem, placed in whorls at their articulations, each whorl consisting of as many branches as there are teeth to the sheath.

2. The *Filices* or ferns seem to approach very closely to Filices. some of the Endogenæ, particularly to the palms, in general habit, and also slightly to the *Cycadææ*, which form part of the Exogenæ; but if our ideas be correct, the affinities that have been traced between them have been much exaggerated.

In our estimation, an entire fern corresponds only to a leaf among the vascular plants; and that part which has been called a *stem* or *rhizoma* under ground, or a *stipes* or *caudex* when erect and above ground, as in the tree ferns, is, we think, analogous to a mere petiole. Each leafy expansion has been termed a *frond*, without sufficient attention having been paid to its origin. But a frond whose stipes pushes out radicular fibres from its base, is, we think, similar to a simple leaf; while those species whose frond is attached to a rhizoma or caudex resembles a pinnate leaf. Thus the ferns do not resemble vascular plants, but only a portion of one. The veneration of all, with the exception of *Ophioglossum* and its allies, is circinnate like the *Cycadææ*; but instead of being rolled inwards, it is rolled outwards, unlike any vascular plant that we remember. As, however, the views here announced have not hitherto been adopted by any botanist, we may, in reference to the terms more generally in use, mention, that every leafy portion which rises above ground is termed a *frond*, and its stalk or support a *stipes*. The creeping part under ground or on the surface is termed a *rhizoma*, and when erect and like the trunk of a tree, a *caudex*. The stipes is flattish or concave on the side corresponding with the upper surface of the frond, and convex on the other. It is *glabrous*, or *rough*, or *prickly*, or *scaly* (*paleaceus*), or *downy* (*pubescens*), as in vascular plants. The frond is said to be *simple*, or *lobed*, or *pinnatifid*, or *pinnatifid*, as in a true leaf. It is even called *pinnate* when there is no membranous connection between the divisions, although there be no articulation at the base of each. In substance also it may vary from rigid and coriaceous to thin and membranous.

3. *Marsiliaceæ*. These are either creeping or floating Marsi- liaceæ.

Glossology. plants; the former have petioles to what are called their leaves, with a circinnate vernation like the ferns. The supposed leaves are of a coriaceous texture, and either consist of three or more wedge-shaped divisions, and are conduplicate when young; or they are entirely abortive, leaving nothing but the petiole, as in *Pilularia*. Those, again, which float have the leaves closely imbricated and sessile, and resemble the *Hepaticæ*, and appear to be involute, or folded together in vernation.

Lycopodiaceæ.

4. *Lycopodiaceæ* are seemingly intermediate between the ferns and mosses with which they were formerly confounded. They have either creeping stems or a cormus, with erect branches, which are either round or angled, and provided with leaves. The leaves vary from setaceous to ovate, are acute, undivided (with only one exception), smooth, and of a thick texture, resembling often in a slight degree those of the pine tribe. In several, however, they are plain and foliaceous; sometimes they are closely imbricated round the stem, or they appear distichous, with generally two other rows of smaller ones, that are appressed, and may be taken for stipules. They have either a middle nerve or none at all. In one genus the leaves are reduced to mere scattered teeth, and in another they are all radical, long, subulate, channelled above, and convex below. Their vernation is straight. They are usually found on mossy ground, sometimes on trees, rarely in or under water.

Eductulosæ.

These are entirely composed of cellular tissue, so that here we find as much uniformity in their internal structure as diversity in the other classes of vegetables; but, by a strange compensation, their external forms are even more varied than in the higher organised plants.

The entire mass of these vegetables appears to be composed of one substance, which takes different shapes, destined to fill different functions, without actually constituting distinct organs. Persoon, in speaking of the mushroom, has named the whole portion that does not serve for the reproduction of the species a *peridium*; Acharius has called it a *thallus* in the lichens; and Lamaroux, *frons* or *frond* in the algæ. De Candolle, again, is disposed to apply the term *thallus* generically to all the nutritive organs combined in the true cellular plants, at least to those of the algæ, fungi, lichens, and hepaticæ; and it would be well if botanists, who have made these tribes their study, had agreed to drop entirely the terms *leaves*, *stem*, or *roots*, which have no real affinity with those of vascular plants, and can be only applied metaphorically. But as they are generally retained in some of these orders, we will continue also to employ them.

Musci.

5. The *Musci* or mosses have most affinity with the ductulosæ, and approach very closely indeed to some of the lycopodiaceæ. What are called their roots consist of slender fibres of a brownish colour, more or less branched and jointed, which spring either from the base of the stem, as in *Phascum*, or along it, as in several species of *Bryum*, in which great part of the stem is sometimes covered with these radicular fibres. The stem is cylindrical, but is said to be compressed, plane, or tetragonal, according to the disposition of the leaves. It is often very short and simple, especially when the plant is annual, but is sometimes branched, either by pushing out roots near the base, or by emitting lateral or terminal branches, each of which denotes usually a year's growth, and they are thus called by Hedwig *innovations*. The leaves arise from the stems, being sometimes collected together at the base, sometimes

at the apex, and sometimes alternate or in a spiral: they are sessile, and embrace the stem at their base; and they have the appearance of oval or elongated scales, rarely obtuse, generally pointed or acuminate, and the point is not unfrequently prolonged into a long hair, or twisted like a cirrus or tendril. Only one instance is yet known where the hair-like point is branched. They are usually entire, but in *Diphyscium* and *Buxbaumia* they are laciniated. Some leaves are deprived of all appearance of a nerve, and are entirely formed of a homogeneous cellular tissue; others present in the middle a nerve variable in length; others again two nerves; and these nerves are formed of cells, which by their union imitate the nerves of vascular leaves. The margin is either entire, crenated, toothed, or serrated; and the serratures are sometimes so fine as to cause it to be called ciliated; but these appearances are not occasioned, as in vascular plants, by (as it were) an incision into the leaf, but arise from a mere contraction of the marginal cellules, more or less evident in the same species, and even specimen, in different states of its growth. The leaves, as we have said, embrace the stem, but sometimes in so very oblique a manner as to form two opposite vertical rows, and thus appear distichous, as in *Schistos-tega pennata*. But this must not be confounded with the structure in that section of *Dicranum* called *Fissidens*, in which the leaf is slightly folded, and the upper portion on each side of the nerve soldered closely together, while the nerve itself is prolonged at the back into an appendage equal to the half of the leaf. Some botanists seem inclined to suppose that these leaves, resembling those of an *Iris*, may be formed by the partial soldering of two closely approximated and obliquely placed leaves; but we are borne out in our view by an examination of the young leaves, either at the very base of the stems, or at the perichæetium, in which they are as in other mosses, the nerve not being yet provided with its appendage.¹

6. The *Hepaticæ* resemble much the mosses, and most of all the genus *Jungermannia*. But here there is no trace of nerves; and at the base of the leaves are often to be found leafy appendages or accessory leaves, falsely called stipules, sometimes united by the side to the leaf, and sometimes distinct from it. There are some species of this genus without these appendages, having the leaves vertical, scarcely at all embracing the stem, but having their margins prolonged down its side, so that the stem resembles a petiole furnished with distichous segments. When these segments are united by the edges on each side, we have a foliaceous limb, and such species are called *frondose*, the midrib corresponding to what is termed the stem in the others. Sometimes this midrib is obscure, as in *Jung. epiphylla*; in *Jung. pinguis* it cannot be traced, so that we may pass to the genera *Anthoceras*, *Marchantia*, and *Riccia*, in which we see only a nerveless foliaceous disc, representing both stem and leaves; pushing out from below, the roots; and from above, the organs of fructification. From the supposed existence of a stem and leaves, both musci and hepaticæ are said to have an axis.

7. The *Algæ* are principally found in water, and consist of expansions, sometimes filiform, sometimes foliaceous, or a mixture of these. Their perfect homogeneity has been acknowledged by all who have studied them, and thus the appellations of frond or thallus has been given to the whole mass of the plant. They present different degrees of consistence; some being coriaceous and of an olive colour, others cartilaginous and of a rose colour; some membranaceous, and others gelatinous. The

¹ Arnott, *Nouv. Disp. des Mousses*, p. 27.

Glossology. large species, in particular, so subject to be tossed about by the violent motion of the waves of the sea, are furnished with a small flat base called a *callous disc*, by which they are fixed to the rocks; and others are provided for the same purpose with short, blunt, and often thick, root-like processes. The foliaceous part of the algæ is often traversed with veins similar in appearance to the nerves in true leaves; but these are merely composed of elongated cellular tissue; while other species are entirely destitute of them. The cells of this tribe are variously approximated in the same plant; and hence we have frequently a sort of bark, distinct as it were from the central portion: sometimes they are arranged so that one cell constitutes the whole thickness of the frond, which thus becomes very thin and membranous; in other cases they are placed end to end, forming threads, as in the *Confervæ*. These threads are moreover usually furnished with disseminations or partitions at nearly equal distances, bearing a pretty constant proportion to the diameter of the thread. The genus *Hydrodictyon* presents a remarkable structure: the frond is composed of numerous pentagons, each of the five sides of which are confervoid threads, that in maturity separate from each other, and give rise to plants similar to that of which they formed a part. *Chara* is supposed to have an axis, the other algæ none; but some species of the fuci and confervæ tribes present as much an axis as the other.

Lichens. 8. Among the *Lichens* the variety of form is still greater. Some present plane foliaceous expansions, as in the hepaticæ; others are of a substance quite gelatinous, as in some *Algæ*. Some have cylindrical stems, more or less branched, of which several are provided with small, plane, leaf-like processes; in other species all these different forms are reduced to so small dimensions that the whole thallus, or nutritive organs of the plant, consists of a mere crust, composed either of foliaceous scales, of small stems compactly placed together, or of a granular or pulverulent matter. The surface presents also much variation: sometimes it is quite smooth; sometimes provided with hairs or ciliæ of different kinds; and sometimes it pushes out fibres, which serve to fix the plant. In many species the thallus, without the intervention of any fibres or roots, is so cemented to the rock or tree on which it grows, that it cannot be detached. In the flat species the two surfaces are very dissimilar, both in colour and structure. But lichens even appear to consist of two distinct layers of tissue. Of these the interior, which Eschweiller has termed the living or medullary portion of the thallus, is imperfectly cellular or filamentous; while the other, the cortical or exterior, seems to be merely formed of the dead cellules of the former, and to serve as a protection to it.

Fungi. 9. The *Fungi* present cells, sometimes round and sometimes elongated, in the form of hollow threads, which are either placed closely together or irregularly separated. Their consistence is variable, being soft or hard, fibrous or gelatinous, fleshy or coriaceous. They never grow in water. Their colours are variable, often vivid, but never truly green. There is scarcely anything that can be termed a frond or thallus; but instead of it there is often a peridium or sporangium, that covers the fructiferous organs; indeed, the whole plant may be viewed generally as a mass of reproductive matter. In the agarics and other allied genera there is a *stipes*, metaphorically called a stem, which arises from a membranous integument, termed a *volva* or wrapper, that in the young state envelopes the whole. The upper horizontal part of these plants is called a cap or *pileus*, which is provided on its under side with thin radiating expansions, termed gills or *lamellæ*, or with fine tubes. Some have a delicate fringe or veil (*velum*), that connects the margin of the pileus at a certain age

Glossology. with the stem: in a few this veil has the appearance of a ring round the stipes, and is then called an *annulus*.

REPRODUCTIVE ORGANS.

We now come to the reproductive organs, or those organs essential to the reproduction of the plant; and under this denomination we comprehend all those parts that are situated beyond the leaves. Linnæus first made the observation, that the parts of a flower were metamorphosed leaves; and this will appear very evident from considering the facility with which any one part changes into another. Thus, leaves gradually pass into bractæ, and the latter have often so much the appearance of true leaves as to be only distinguished from them by their position. Between bractæ and bracteolæ there is scarcely a limit; and either of these, when immediately under the flower, is often liable to be confounded with the calyx, or supplies the place of a calyx. Again, between a calyx and corolla there is the closest resemblance; so much so, that when one only was present, it has been a matter of dispute by what name it ought then to be described;—Jussieu and his followers calling it uniformly by that of calyx, but Linnæus pronouncing it a calyx only if green, and a corolla if coloured; whilst more modern botanists, to avoid a discussion attended with little good, have adopted instead of it the ambiguous term *perianth*. But horticulture shows this affinity in a still more striking degree; many of the primrose tribe in cultivation having the calyx changed into a corolla placed under the true corolla, and in every respect similar to it. In a double flower, all are aware, the stamina change into petals; and in the water-lily (*Nymphæa*) it is no easy matter to draw the respective lines of demarcation between stamens, corolla, and calyx. It is more difficult to admit at first the connection between the fruit and the others, instances of the metamorphosis being more rare. Thus, in half double flowers, the fruit, or parts of the fruit, or carpella as they are called, remain often unchanged, as in the peony; but in many truly double flowers, as among the pinks and carnations, every portion of the fruit is actually transformed into petals. On the other hand, in *Magnolia fuscata*, the stamens actually change into carpels; and we have specimens before us, exhibiting the same change in the *Salix Croweana*. In some species of *Ononis*, and the other genera of leguminous plants, in which there is usually one perfect carpel, we have seen it transformed into a leafy process, demonstrating that the carpel is nothing but a folded leaf.

The parts belonging to the flower, though thus primarily alike, yet differ much afterwards, particularly in their physiology. The more foliaceous parts, as the bractæ, calyx, and corolla, serve for the nutriment or protection of the others, which are more immediately called the sexual organs. In several parts of the flower we may distinguish the portions of the leaves of which they are composed, so as to detect more or less clearly the petiole and the lamina. Thus, in a calyx the sepals are usually formed by dilated petioles, although in the roses the lamina also makes its appearance. Of the corollas, the petals represent in general a dilated petiole; but sometimes an unguis or claw may be noticed, as well as a limb, conformable to the petiole and lamina of a leaf. Among stamina, the filament is the petiole, while the anther is produced by each side of the lamina being rolled inwards, and forming two loculi or bags. The carpels are formed by the folding of the lamina of a leaf, the ovules arising from the extremities of the lateral nerves. Here the petiole is often wanting, though in several genera of *Leguminosæ*, in the caper plants, and others, it is very distinct.

From what we have now said, it may be laid down as an

Glossology. axiom, that a flower is an assemblage of several whorls of foliaceous origin, arranged above or within each other, so closely that the internodia, or distance between each series, is not distinguishable. But this will be better understood when we come to the definition of the particular parts.

Inflorescence.

Inflorescence is the ramification of that part of a plant intended for its reproduction; or, in other words, it is the mode in which the flowers of a plant are distributed. The organs peculiar to it are peduncles, pedicels, bractæ, and bracteolæ or the accessory envelopes to the flowers.

As leaves are lateral, so must also be the parts of the flower, hence we might naturally expect the floral stem or branch to be prolonged beyond it; and this indeed often happens in monstrosities, as in some roses and pear trees; but otherwise the flower absorbs all the nutriment from the branch destined to that purpose. Thus we may state as a general law, that a flower is terminal on the little branch that supports it; and this branch is termed a *peduncle* or *pedicel*. The pedicel with the flower being thus precisely similar to a branch and its leaves, the flower-bud which gives rise to such must be analogous to leaf-buds; and the great difference between them is, that the latter elongate indefinitely in the form of branches, while the former do not elongate beyond the flower.

Flower-buds always, therefore, like leaf-buds, are terminal, or arise from the axils of leaves, which leaves are called *bractæ* or floral leaves; and those leaves which appear on the pedicel, between the bractæ and calyx, are called *bracteolæ*. These are often confounded, but are nevertheless essentially distinct; the former belonging more to the stem, the latter to the flower-bud. Bractæas and bracteolæ are often beautifully coloured, the more so, usually, the nearer they are to the flower. When a single one is rolled together, highly developed and coloured, and is placed at the base of the form of inflorescence called a *spadix* (fig. 53, *b*), it is named a *spatha* (fig. 53, *a*); and the upper ones, arising among the flowers themselves, are termed *spathellæ*. When several are verticillate, or densely imbricated around the base of the form of inflorescence called an umbel or capitulum, they are termed an *involucrum*; and those at the base of each partial umbel are called *involucella*. In the grasses there are usually two at the base of the spikelets, which receive the name of *glumes*; while the small ones surrounding each floret in the spikelet, called *glumellæ* or *paleæ*, may be viewed as involucella. Small imbricated bractæas are often called *scales*, as in the thistle and artichoke. On dissecting the capitulum of flowers of many of the *Compositæ*, small colourless bractæ may be perceived at the base of the florets;—these have received the name of *paleæ*, but they appear to be a mere continuation or modification of the scales of the involucre.

With regard to the axis of inflorescence and its bractæ, sometimes the axis itself, but more usually the branch which springs from it, is termed a *peduncle*. These peduncles often bear bractæ, from the axils of which arise secondary peduncles. The same may again happen, and the ultimate support to the flower is then termed a *pedicel*. A pedicel may be clothed with bracteolæ; but these have no flower-buds in their axils, and therefore each can only, strictly speaking, bear but one flower. In the honeysuckles there appear to be two flowers and two fruits to each stalk, but this is caused by the combination or union of the two pedicels that terminate the axis. When two or more pedicels spring near to each other from the axis of inflorescence, the axis is termed a *rachis*. Those axes that spring out of the earth, and bear no true leaves, are denominated *scapes*. Pe-

duncles are usually cylindrical or slightly compressed; in *Glossology*. *Xylophyllum* it is said to be flat or foliaceous, but this appearance originates rather from the expansion of the axis or rachis than of the peduncle itself. In the case of an umbel, the axis tends to dilate at the apex, and this dilatation seems to depend on two causes: it is either in proportion to the number of flowers that ought to be on the summit, or it becomes the larger the more sessile the flowers are on the horizontal expansion. That kind of umbel found in thistles and other compound flowers is a remarkable illustration of this: the expansion on which the flowers are situated here bears the name of *receptacle*; some few botanists calling it also, in particular cases *phoranth* or *clinanth*. These receptacles are sometimes quite flat, sometimes conical or cylindrical, and sometimes concave; and in the fig the margins of the receptacle are so approximated as to represent a bag, on the interior surface of which all the flowers are seated. By many botanists the axis of inflorescence is termed the peduncle, and the peduncles pedicels. But it is impossible here to lay down any certain rules by which these may be understood, the same author at different times using the same terms with a different meaning.

The inflorescence of plants is very various, and depends entirely on the power of developing the flower-buds in the axils of the bractæas. Two points are, however, common to all the forms: all must be axillary, or a modification of that, and have the flowers terminal on the peduncles or pedicels. They may be reduced to two classes: *simple*, when it is formed by the development of one bud and one branch; or *compound*, when it is formed by the development of several buds or branches.

Simple inflorescence.—When a flower-bud gives rise to only one flower, terminal on its peduncle, and the axis of the plant does not elongate beyond the bud, the flower is commonly called *terminal* and *solitary*. When, however, the axis continues to elongate, and the bractea retains the form and size of a leaf, the flower is called *axillary* and *solitary*. But if the buds, instead of giving rise to one terminal flower, have the axis elongated, bearing several flowers, and each flower on a peduncle, a *raceme* is produced; and when each flower is sessile, or placed in the axil of the bractæ, without a peduncle, a *spike* is formed. The difference between these two is very slight, or, more properly speaking, a spike is a mere conventional term, to imply those cases where the peduncle is scarcely perceptible; and, by the aid of horticulture, the one is frequently made to pass into the other. When the bractæas are nearly equal in size and closely imbricated, and the spike articulated with the stem, it is termed an *amentum* or *catkin*: but this articulation is often not to be detected; thus, in some willows, the male catkins fall off, while the female are permanent. The real spikes of the grasses are commonly termed *spikelets* or *locustæ*; and when we there speak of the flowers being in spikes or panicles, we actually mean that the spikelets are arranged in spikes or panicles. The *spadix* (fig. 53, *b*) is a sort of spike, in which the flowers are closely packed together upon a succulent axis, which is enveloped in a coloured convoluted bractea or spatha: the spadix is usually simple, but in some palms it is branched. A *raceme* differs, as we have said, from a *spike* by having the pedicels that issue from the bractæas more elongated. When a raceme has its peduncles spreading, elongated, and bearing bractæ, and pedicels again arising from these bractæ, a *panicle* is formed. Usually in these two the lower peduncles are only slightly longer than the others; but when they are very long, and the upper ones very short, it is commonly termed a *corymb*. But this appellation was given before the subject of inflorescence was properly studied, and with De

Glossology. Candolle we feel inclined to adopt here the terms *corymbose raceme*, or *corymbose panicle*. When the axis of a raceme is so very short that all the peduncles issue from one point at its apex, we have a simple umbel; and when the same happens to a panicle and to its branches, a compound umbel is formed. In these frequently the bractæ fall off early, or are abortive. A *capitulum* may be either a spike, raceme, or umbel, in which all the flowers are placed together in a globular head. Capitula also differ from each other by the form of the axis, many kinds of which may be seen among the *Compositæ*. Now, as all these different kinds of inflorescence spring from a solitary flower-bud,—and as a flower-bud is quite analogous to a leaf-bud,—and as in a leaf-bud the outer or lower part is first developed;—so in a spike, a raceme, a panicle, an umbel, or a capitulum, the lower flowers are first expanded, and this mode of flowering or order of expansion is called *centripetal*.

Compound inflorescence, or when the inflorescence is the result of the expansion of several buds or branches.—The most perfect instance of this is a true *corymbus*. Here the axis of the plant assumes the appearance of an axis of inflorescence, developing flower-buds which follow the centripetal order of expansion; but as it is a continuation of the axis of the branch, and as we have already observed that those leaf-buds nearest to the summit are first developed, so, in a compound inflorescence, the flower-buds towards the extremity of the axis are first evolved, and the lower ones the last. In a *corymbus*, then, each particular branch follows the centripetal law, while the whole mass of inflorescence proceeds in an inverted order. Although we have only referred to the *corymb* generally as a mode of inflorescence, individually it resembles a raceme, of which the lower flowers have long, and the upper ones short pedicels. The *Achillea millefolium* will well illustrate the *corymb*; each of what is commonly called the flowers of such a plant being a *capitulum*. Now, let us suppose that the *capitulum* of such an inflorescence is by some means reduced to a solitary floret,—and approximations to this are to be observed in many *Compositæ*,—we shall then have a *cyme*, in which the solitary central flower is first developed, and, lastly, the lower ones. This kind of expansion is called the *centrifugal*. Viewing, with De Candolle and Roeper, the terminal bud by which a branch is prolonged, as similar in all respects to a true leaf-bud, and supposing in the same way the existence of a terminal flower-bud, this kind of inflorescence has received the name of *terminal* or *definite*, because the flower being supposed to occupy the extremity of the branch, no more can be formed beyond it; while the centripetal inflorescence has been termed *indefinite* or *axillary*, because the axis being never terminated by a flower-bud, it may be elongated until there be no more juices left for the further development of the flower-buds. The term *cyme* is usually applied to those cases in which the primary branches issue from the same point, while the smaller branches are unequal, starting from different points, but elevating the flowers so that they may be nearly all in one horizontal plane, as in the elder or dogwood. But this is not always the case: the central portion may be elongated; and then, when the peduncles and pedicels are relatively opposite to each other, as in *Erythraea*, we have what are called dichotomous cymes. A *fasciculus*, on the other hand, is a contracted cyme, in which the lateral branches are very short, and the flowers are clustered together, as in many of the pink tribe. A *glomerulus* is when the cyme is so contracted, and the ramification is so little apparent, that it has been usually confounded with a true *capitulum*. This disposition is of rare occurrence, but is to be observed in some *Compositæ*. The last form of inflorescence we

shall notice is a *thyrsus*; and this may be conceived to be composed of cymes, arising from the axils of the leaves of a branch as it is successively developed. Thus the sage, the thyme, and the labiate plants, exhibit a *thyrsus*. The stem or branch is prolonged indefinitely, of which the lower flowers first make their appearance; but the inflorescence that proceeds from the axil of each leaf is a true cyme, in which the terminal flowers are first expanded.

If we be correct in what we have stated, the centrifugal mode of expansion is a reduced form of the centripetal, combined with the mode of development of branches. It ought, therefore, to be scarcely distinguished from the other; and cases do occur only referable by analogy. Roeper and De Candolle, who admit the existence of terminal flower-buds, observe that the terminal mode has two opposite bractæ, while the axillary has but one; and they apply this test with great ingenuity to the case of a solitary peduncle and flowers, in order that it may be referred to one or the other of the two classes.

Torus.

The *torus*, or the proper receptacle of the flowers, is an expansion of the pedicel, from which spring the petals and stamina, and seems to be formed by an abortion or partial development of one or both of these parts. Although, therefore, not properly by itself an organ, it is of great importance in the structure of flowers; for not only do the stamens and petals arise from it in the state in which they usually appear to us, but even when these are transformed into nectariferous glands, or into those doubtful bodies sometimes confounded with stamens and sometimes with petals. These appearances may therefore be met with either outside of the petals, or inside of the stamina, or between these. Usually, however, the torus is inconspicuous, and is reduced to a narrow circular space between the calyx and the pistil. When this zone is under the ovary the petals and stamens are said to be *hypogynous*, and the plants are termed *thalamifloræ*. But frequently the external part of the torus extends itself along the bottom or the interior of the calyx, and the stamina and petals are said to be *perigynous*, and the plants are called *calycifloræ*. When the inner portion of the torus expands along the pistil in a greater or less degree, the stamens and petals then seem to arise from the pistil, and are denominated *epigynous*. But there is still another case, when the torus extends both along the calyx and the pistil at the same time; and a necessary consequence of this is, that the tube of the calyx adheres to the pistil. The petals and stamens thus spring from a zone round the apex of the fruit, and between it and the calyx, and seem to be seated on the fruit itself; an appearance which has induced botanists to apply to it also the term *epigynous*. But if these two kinds of *epigynous* insertion were to be considered as but one, so ought in the same way what is called *perigynous* to be viewed as a modification of the *hypogynous*; for in the *perigynous* the torus, though connected with the calyx, was distinct from the fruit, and as much under it as in the true *hypogynous*; and, strictly speaking, both the *perigynous* and second kind of *hypogynous* may be regarded as combinations of the other two. Most modern botanists have, however, considerably altered the signification of some of these terms, especially when speaking of the insertion of the stamens. According to them, when the stamens contract no adhesion with either the calyx or the pistil, they are *hypogynous*; when they do arise from the calyx, but are free from the pistil, they are said to be *perigynous*, and such does not differ from the view we have taken above; but when the stamens contract an union with both the surface of the calyx and the pistil, they are

Glossology. termed *epigynous*, while the true epigynous insertion, or where the stamina are united to the style, but free from the calyx, receives the name of *gynandrous*. We think it right to state here, that it is in the altered sense that epigynous is now usually adopted in systematic works. When the torus is conspicuous, and of a fleshy nature, it is often known by the name of *disc*. To those bodies between the calyx and pistil, unlike either the stamens or petals, of the nature of which Linnæus was uncertain, he gave the general name of *nectary*.

Floral Envelopes.

These immediately surround the sexual organs, and are formed of one or more whorls of variously modified leaves. When there are two whorls, the plants are termed *dichlamydeæ*, and the outer is called a calyx, the interior a corolla.

Calyx.

The *calyx* is usually of a green colour, and foliaceous; each segment is termed a *sepal*; those like leaves are sometimes articulated at their base, when they are either quite distinct from each other, or cohere in the form of a lid (as in *Eschscholzia*) during the flowering of the plant. But they are often continuous with the peduncle, and consequently persistent. In such cases they are either distinct, or are united together by their margins. When the sepals are distinct, the calyx is said to be *bi-, tri-, or poly-sepalous*, according as there are two, three, or many leaves; and when soldered, it is called *gamosepalous*, or, by the strict followers of the Linnæan nomenclature, *monophyllous*; when only slightly united at the base, it is *partite* (*bi-, tri-, quadripartitus*, &c.); when united to the middle, it is termed *divided* (*bi-, trifidus*, &c.); and when soldered till near the apex, it is called *toothed* (*bi-, tridentatus*, &c.). If no teeth be perceptible, it is then *entire*; and in that case the number of parts must be determined analogically, or by other means. The cohering portion is termed the tube. Some sepals in the same calyx may cohere together in a greater degree than the others, and this gives rise to a *bilabiate* calyx. In a few genera with articulated sepals, the divisions cohere together, but separate from the tube in the form of a lid or operculum. Sometimes the calyx is reduced to a mere ring round the base of the corolla. In the Valerians this ring is afterwards developed into a *pappus*, formed of numerous long and fine radiating segments. In many *Compositæ* the margin of the calyx also constitutes a pappus, appearing either in the form of a ring, or bristles, or scales, or rough hairs (*pilosus*), or feathery hairs (*plumosus*). The calyx may be free from, or unattached to, the fruit; or the tube may be closely incorporated with it, or *adherent* (*calyx adhærens*).

Corolla.

The *corolla* is for the most part more or less coloured; and it exists in the greater part of the Exogenous plants. Sometimes it is very small, and reduced to the appearance of mere scales, and even in some genera is quite abortive; and when this happens, we must proceed with the greatest caution, and depend much on analogy, so as not to confound those groups of plants in which it ought to be present with those furnished with a perianth, in which a true corolla is always supposed to be absent. The divisions of the corolla are called *petals*. They are almost always articulated at the base, and consequently fall off; and when this happens at a very early stage, they are said to be *caducous*. When the petals have no articulation, as in *Campanula*, they either remain for a long time, or are *persistent*; or are *marcescent*, when they wither away without falling off. When the petals are quite distinct from each other, the corolla is *polypetalous*; or, when more or less united by

their margins from the base upwards, *monopetalous*, an incorrect term, which ought to be exchanged for *gamopetalous*; and then it may be *partite*, *divided*, *toothed*, or *entire*, in the same way as in the calyx. But petals may also unite in their upper parts, though distinct below. The vine, and the keel (*carina*) of a peablossom, or other papilionaceous flowers, exhibit this structure. When the lower part of a petal, as the petiole of leaves, is narrow, and consists of the union of all the vessels that expand and ramify in the upper portion, the contracted part is the *claw* or *unguis*; the dilated, the *limb* or *lamina*. If the unguis be long, straight, and closely approached to each other, even though distinct, a kind of *tube* is formed; but, properly speaking, it is only a tube when the claws are united. The orifice of the tube is termed the *throat* or *faux*; and this may be *naked* (*nuda*), or furnished with little *scales* or appendages, called sometimes a *crown*. The shape of the corolla is frequently of importance in distinguishing natural groups of plants. When all the petals are equal, it is said to be *regular*: when a monopetalous regular corolla has no tube, but swells out gradually from the base to the summit, it is *bell-shaped* or *campanulate* (fig. 54); and *urceolate* if it is swollen at the base, and contracted at the top: when there is a tube, and when it is narrow below, but dilates upwards, so that the limb is campanulate, the corolla is *infundibuliform*, or *funnel-shaped* (fig. 55): it is *rotate* (fig. 56) or *wheel-shaped* if the tube be very short, and the limb spreading and nearly plain; *hypocrateriform*, (fig. 57) when the tube is long, narrow, and cylindrical, and the limb spreading like a star; and *tubular*, when it is almost entirely composed of a narrow elongated tube, slightly dilated upwards; but this may be viewed as a very slender state of the infundibuliform. When the petals are unequal in size, or cohere unequally, the corolla is *irregular*; and if such petals unite, we shall have an irregular monopetalous corolla, which is said to be *labiate* or *bilabiate* (fig. 58) when the tube is more or less elongated, the throat open and dilated, the limb divided transversely into two parts or lips (*labia*), the one superior, the other inferior, which lips are subject to various modifications, one of the most curious being where the upper lip is so slightly developed as to appear to be absent, as in *Teucrium*. A *personate* (fig. 59, 60) or mask-like corolla is when the tube is more or less elongated, the throat very dilated, but closed up by the approximation of the limb, which has two unequal lips, as in the snapdragon; but it is often very difficult to distinguish between personate and labiate flowers. When the upper part of the tube of the corolla is split down on one side, and becomes flat, it is what is called *ligulate* (fig. 61), as in the hawkweeds, or exterior flowers of the daisy. A regular polypetalous corolla is said to be *rosaceous* (Plate CXIII. fig. 62) when composed of three, four, or five, rarely more petals (fig. 62, a), of which the claw is very short, and the lamina diverging from each other, as in the rose. When there are five petals, the unguis of which are elongated, forming a false tube, and concealed within the calyx, the corolla is *carophyllate*, as in the pinks; and when there are only four petals, with long straight claws (fig. 63, a), and patent lamina, forming as it were a cross, the corolla is *cruciform* (fig. 63), as in the wallflower; but it is not essential to this last, that the petals be perfectly alike and equal to each other. Of irregular polypetalous corollas, the only one that has received any particular designation is the *papilionaceous* (fig. 64). Here there are five petals; the upper one is usually larger than the others, and covers them before the flowers expand, and is called the *vexillum* or *standard* (fig. 64, a), from its resemblance to a flag; the two lateral ones, like the wings of a butterfly, are the *alæ* or *wings* (fig. 64, b); and the two lower ones, usually more or less

Glossology. united together by their lower margins, representing the keel of a ship, have been called the *keel* or *carina* (fig. 64, Pl. CXIII. c). Such a corolla belongs only to the *Leguminosæ*. In the case of an irregular corolla, whether *monopetalous* or *polypetalous*, one of the petals is sometimes provided with a tubular projection, when it is said to be *spurred* (*corolla calcarata*, fig. 60).

Perianth.

The *perianth*, called also *perigonium*, as we have already stated, is that ambiguous form of envelope which partakes somewhat of the appearance of a calyx, somewhat of a corolla. The Exogenous plants which possess this are called *monochlamydeæ*; and it exists in all the Endogenæ. One must not confound with these the plants in which the calyx and corolla is either deciduous or abortive. The parts of a perianth are strictly termed *tepals*. A corolla being never incorporated with the fruit, as many perianths are, there is a presumption that the latter are more of the nature of a calyx; and an anatomical examination of their external surface confirms this supposition. The internal and often coloured surface, however, is different, and is probably either the torus, or a petaloid expansion of the torus. Not only are the petals often absent, but even in some cases there is scarcely a rudiment of a perigonium, as in the genus *Euphorbia*.

Estivation.

As any law by which sepals and petals are disposed must obviously be very intimately connected with their *estivation*, or primitive arrangement in the flower-bud, so the estivation, or *præfloration* as it is sometimes called, though long neglected, has of late years been made to bear an important part in the classification of plants. The principal modifications are the *valvular* estivation (fig. 65), when the parts of an envelope are either plane or slightly convex, and merely touch one another by their margins, without the one covering any part of the contiguous one. When the parts are each closely folded together, and unite one to another by their margins into a monopetalous corolla, as in *campanula*, it is sometimes said to be *plicate* (fig. 66); but this is only a modification of the valvular. When they are slightly concave, and a margin of one slightly covering the margin of another, while its other margin is usually in its turn covered, the estivation is *imbricated* (fig. 67, a); but of this there are several variations. When an imbricated estivation is spirally twisted, which seldom happens, except when the parts are more or less respectively soldered together, it receives the name of *twisted* (fig. 67, b) or *contorted* (*æstivatio torsiva*, or *contorta*). In some plants the petals are folded irregularly, or crumpled, when their estivation is said to be *corrugated* (*æstivatio corrugativa*), as in the poppy; but this last ought rather to be considered as merely arising from an extraordinary development of the petals. Thus the petals of the *Cistus*, independent of being corrugated, are also twisted. When there are more than one series of parts of the same envelope, as in the water-lily, where there are several rows of petals, these alternate with those of the adjoining rows; each row or series may have its own mode of estivation, while, as a whole, it is termed *alternative* (*æstivatio alternativa*); in the spider-wort (*Tradescantia*) the outer row of the perigonium has a valvular, and the inner a corrugated and imbricated estivation. Again, when the same envelope may have two kinds, it will be readily allowed that the calyx may have one and the corolla another. Thus, in the mallow tribe, the calyx is valvular and the corolla twisted; in the flax and gum-cistus, both parts are twisted, but the corolla is twisted in an opposite direction to that of the calyx.

Sexual Organs.

Many of the ancient philosophers were well aware that there was a difference of sexes in plants as well as in animals; and Theophrastus even states, that the fruit of the female palm will not germinate, unless the pollen of the male be shaken over the spatha of the female when both of them are in flower; but it was not till the time of Grew that any thing certain was understood on the subject. He was the first who regarded the stamens as the male, and the pistilla as the female organs. Linnæus afterwards improved on Grew's ideas, and has adduced so many proofs from theory, and, what is of greater importance, from experiments of a tedious and delicate nature, that none now can experience the smallest doubt. An account of his arguments and experiments, and others of a late date, with the mode in which fecundation is supposed to be accomplished, forms one of the most interesting parts of vegetable physiology.

Stamens or Male Organs.

Each male organ is a *stamen*; but the whole taken collectively forms the *androcaum*, a term that bears the same relation to stamens as a corolla does to petals. These are situated between the petals and pistilla. Although a calyx and corolla be usually present in flowers, yet we have seen that they are not essentially necessary; but no plant can produce seed without the assistance of stamens and pistils, or their modifications. When stamens and pistils occur in the same flower, it is termed *perfect* or *hermaphrodite*; but, as sometimes happens by abortion or other causes, the stamens appear in one blossom and the pistilla in another. Again, according as these are on one or on different individuals, the flowers are called *monœcious* or *diœcious*; and, generally speaking, the flowers are *imperfect* or *diclinous* (*flores diclines*).

The number of stamens is variable, five or ten being the usual number among the Exogenæ, and three or six among the Endogenæ; but, on the one hand, these are subject to abortions, and on the other to multiplication. When the last takes place, it is by the addition of one or more rows similar to the first; so that although apparently indeterminate, they are actually a certain multiple of the primitive number.

A stamen consists of a *filament* (fig. 68, a) and an *anther* (fig. 68, b). The former is the body, which arises from the torus, and is sometimes cylindrical, or awl-shaped, or prismatical, and is even at times expanded, as if into a scale or petal. It is either articulated or contiguous with the torus. Part of it is often united with the petal, particularly when the petals themselves cohere; and the stamen is then called *epipetalous*. Its length is generally proportioned to the style, but it is sometimes wholly wanting, presenting a sessile anther. In the same flower the filaments are generally equal in length, and such are called *isostemonæ*, but in many they are unequal. In *Geranium* and *Oxalis*, where there are ten stamens, five are larger than the other five, and alternate with them. When there are six stamens, of which four are larger than the other two, as in the cabbage, mustard, and the other *Cruciferae*, they are called *tetradynamous*; and where there are four, of which two are longer than the other two, they are *didymous*, but here there is usually the rudiment of a fifth stamen, dissimilar from all the others. The direction of the filaments is usually straight, but they are in some plants bent inwards, in others outwards. In *Parietaria* (the pellitory of the wall) they are *reflexed*; for here the filament is bent backwards in such a way that the upper half lies along the lower, and between it and the perigonium. When the filament is too slender and weak to support the

Glossology.
Pl. CXIII.

Glossology. weight of the anther, and hangs down, it is *pendent*; when it bends towards the lower part of the flower, it is *decumbent* or *declinate*; and when to the upper part, *ascendent*. Pl. CXIII. The filaments are usually *free*, or isolated from each other; but they are sometimes united more or less upwards from their base into a column or *androphore*. When there is one androphore or bundle of filaments, the stamens are *monadelphous*; when two androphores, *diadelphous*; and when several androphores, *polyadelphous*.

Anther.

The *anther* is a kind of bag borne by the filament, and corresponds to the lamina of a leaf. It is either sessile, when there happens to be no filament, or it is placed at the top of the filament in three ways: it may be attached by the middle of its back to the slender apex of the filament, and is then *oscillating* or *versatile* (fig. 73); or it is attached by its base to the top of the filament, with which it then seems continuous, and is then *erect* (fig. 69); or it adheres to the filament by its back, and is then *adnate* or *adherent*, in which case the filament is often prolonged into an appendage. When adherent to the inside of the filament, it is said to be *introrse*, and to the outside *extrorse*. Each bag or cell of the anther is called a lobe; and the solid substance that connects them, and which in fact corresponds to the midrib of the leaf, is the *connectivum* (fig. 69, a). Usually the connectivum is very small and inconspicuous, but in some plants it is prolonged into an appendage, that may be confounded with an elongation of the filament; in others it is prolonged below, as in some heaths, into an awn or crest; in a few it is so broad that the bags of the anther are at a considerable distance from each other (fig. 70). Usually each anther has two lobes; but in a few plants there is only one, and this may happen either from some natural conformation of the plant (and only when the anther is erect), but more generally from the accidental abortion of one of the lobes (and then particularly when the lobes are distant), or by the filament happening to be split, each half bearing a lobe, and representing a distinct stamen. The reverse also happens, so that each anther may appear to consist of four lobes; but this arises either from each lobe being divided into two cells, by the back of the lobe being folded inwards; or it has really four, six, or more lobes (as in some willows), caused by the adhesion of two, three, or more stamens into one. The lobes or cells of the anthers open in different ways, by what is termed the *line of dehiscence*. This usually indicates the margins of the lamina of the leaf out of which the anther is formed, and therefore the most frequent position of this line is longitudinally along the middle of each lobe (fig. 71), in which case the anthers are *bilocular* or *birimose*. When this line does not open during its whole length, but only above or below, exhibiting two pores, as in the heaths, the anther is styled *biporose* (fig. 68); or when there is only one lobe, it is called *one-pored* (*poro simplici*). Very rarely, as in the lavender, the anther dehisces *transversely*; but the most singular case is when it opens by *valves*, as in the barberry and the laurels (fig. 72), that are free below, and hinged as it were by their upper edge. The anther has various shapes; the principal are *globular* when the two lobes form one globe, *didymous* when each of the two lobes are globose; the terms *linear*, *sagittate*, *cordate*, *reniform*, &c., are also to be applied to it in the same way as to leaves of plants. When the filaments are united, the anthers may be so likewise, as in *salix monandra*; or they may be free. But although the filaments may be free, the anthers may be united to each other by the margins, as in the *Compositæ*, and such are then called *syngenesious*. In *Stapelia*, where the loculi or cells of the anther are at a distance from each other, each coheres with the loculus of the neighbouring anther.

Pollen.

An anther contains and frequently emits a matter call-

ed *pollen*, the use of which is to give life to the ovule or young seed. The grains of pollen seem to arise from the extremities of the veins which are found in the leaf that constitutes the anther, and are probably formed from the spiral vessels. When the grains of pollen burst, they again discharge a multitude of very minute particles, called *molecules* or *granules*. When the grains of pollen easily detach from each other, they are said to be *pulverulent*, and then they may be either perfectly smooth without any viscous coating, or they may be viscous. Sometimes the viscosity is not at once perceptible, but may be traced by means of papillæ or small eminences on the surface, which are in fact secretory organs, giving rise to the viscous surface. The nature of these grains of pollen seems constant in each family of plants; and even the shape of these grains is sometimes of consequence in distinguishing natural tribes. In the *Asclepiadæ* and *Orchidæ* the grains are not pulverulent. Instead of separating readily, all the pollen contained in one cell or bag coheres into what is then termed a *pollen-mass*; or when each of those are divided into two or four portions, each is sometimes called a *mas-sule*. When in the *Orchidæ* these pollen masses are formed of grains united together by means of an elastic tissue, they are said to be *sectile* (as in *Orchis*); but in *Epipactis* and others they are *granulose* or *farinaceous*; and in *Coralorrhiza* and *Malaxis*, &c., they are of a solid compact substance.

Pistils or Female Organs.

The whole female organs in a flower, taken collectively, have been named *gynæceum*. This may consist of one or more *pistilla*, or distinct portions. Thus, in the primrose there is truly one, in *Ranunculus* many pistilla. The female parts being, like the stamens, petals, and sepals, formed of modified leaves, each pistillum may arise either from one such leaf or from the combination of several. These component parts are called *carpels*, and are placed in the centre of the flower. They may be arranged, 1st, round a real axis or column, which is the abortive prolongation of the pedicel, and are united to it by their inner angle: this is evident in *Malva* and *Lavatera*, and in *Euphorbia*. 2d, They may be verticillate round the central column, but hanging from its summit, and consequently only attached to it by the apex of the inner angle, as in *Geraniaceæ*. 3d, They may be verticillate round the summit of the axis, but erect, and only adhering by their inner angle at its base; and then the axis may be extremely short, as in *Sedum* or *Aconitum*, or it may be slightly prolonged, as in some rutaceæ. 4th, The carpels may be placed in a spike round the central column, as in the magnolias and tulip-tree, and some ranunculusses. 5th, But if the column be very short and round, the carpels, instead of forming a spike, will form a head round the column, as in the strawberry, where the column is fleshy. 6th, If the exterior portion of the axis be prolonged along the inner surface of the calyx, while the central part is not, we shall have a hollow cup, in the interior of which the carpels are seated, as in the genus *Rosa* or rose; and here the expansion of the axis is united to the tube of the calyx by means of the torus. All plants in their primitive state seem to have several carpels in each flower, but they may be reduced to a solitary one by abortion.

Each carpel (fig. 74) may be viewed as a folded leaf, of which the petiole seldom appears; but when it does it is called a *thecaphore*, or support to the fruit. The *ovules* or young seeds arise from the extremities of the veins, and therefore are usually attached near to the margins of the leaf, or, as it is folded, to both sides of the inner angle of the carpel; and the parts to which they are fixed are called the *placenta*. The ovules, like the pollen of an anther

Glossology. cannot probably be formed without the assistance of spiral vessels, and therefore are not to be looked for in the ferns, which are destitute of these elementary organs. The portion above the thecaphore, containing the ovules, is the *ovarium* (fig. 74, *a*). But the summits of the placenta are prolonged into two thread-like bodies, sometimes long, and sometimes very short. These are usually combined into one, which is then named the *style* (fig. 74, *b*); and its glandular apex, fitted for the absorption of the vivifying part of the pollen, is the *stigma* (fig. 74, *c*).

The carpels show a still greater tendency to unite with each other than even the exterior parts of the flower, though often this union seems to take place in a very slight degree. In *Stapelia* they appear to cohere only by the stigmas; in *Asclepias* by the stigmas and styles; in some by the ovaries alone, in others by the ovaries and styles; but the most complete is by the ovaries, styles, and stigmas. When the styles are united there is usually said to be but one, although the pistil ought more properly to be then called *gamostyle*; and in the same way, when the ovaries are united, there is still said to be one ovary, called by Linnæus a *germen*, consisting of a number of cells (*loculi*), although each of the cells is in fact an ovary.

The number of stigmas is determined by that of the carpels and styles, or their divisions; so that in a compound ovary, when we speak of one stigma, we actually mean several united into one mass (fig. 75, *c*), as in the primrose. It is *sessile* when there is no apparent style, *terminal* when placed on the top of the style or ovary, and *lateral* when attached to the sides of these organs. In substance it may be *fleshy*, *glandular*, or *membranaceous*, and even *petaloid* when it resembles a petal, as in the iris. Its form needs no illustration further than, when several are only partially combined, they are said to be *bifid*, *trifid*, or *multifid*, as if there were actually a simple one variously divided. Its surface is either *smooth* or *pubescent*; in some plants it is *penicilliform* (fig. 76), or of hairs forming a small tuft; in others, as in *Anemone*, *Clematis*, and many grasses, it is *plumose* (fig. 77), or furnished with hairs arranged in a line on both sides, like the vanes of a feather; and is *aspergilliform* (fig. 78) when the hairs are placed in many whirls around the stigma, like a bottle-brush. In a few orders, as *Goodenoveæ*, *Scavoleæ*, and *Brunoniaceæ*, the stigma is enveloped in a peculiar membranous appendage, called an *indusium*.

The *style* is in common language said to be *simple* (*simplex*), or *single* (*unicum*), either when it is the style to one carpel (fig. 74, *b*), or is formed by the union of several into one body (fig. 75, *b*), and is *divided* when the component parts are more or less adherent. But a style in its simplest state, being actually formed by the prolongation of the two placenta of a carpel, is even then a compound body. What are said to be two styles in the grasses (fig. 78) is thus in reality but one divided style. The two stigmas in *Compositæ* indicate the same structure, as well as those of many *Euphorbiaceæ*, where the divisions of the style and stigmas are double those of the carpels. The style may be included within the flower (*inclusus*), or protruded beyond it (*exsertus*). It is usually *terminal* in a compound ovary; and *lateral*, or *basilar* (from the base), in a simple one. In some plants with a deeply lobed ovary, the individual ovaries are attached to each other almost only by their bases; and hence the united style, springing from the point of union, forms as it were a continuation of the axis. The style is of various

shapes, but the most singular is when it is petaloid, as in the iris. It may be straight, or declinate, or ascending.

When no union takes place among the carpels, the *ovarium* is termed *apocarpous*, as in *Ranunculus*; and when there is an adherence, so that a compound ovary is formed, it is called *syncarpous* (fig. 75). In the former case there may be one or more pistilla, according to the number of carpella; in the latter only one. The ovary being formed of the lamina of the leaf, the edges of which may be sometimes rolled inwards, it is evident that we may have each carpel of two cells, as in *Astragalus*; but the division is very seldom perfect. When the ovaria are united into a compound or syncarpous ovary, the sides of the component leaves or ovaria (which sides are then termed *dissepiments*) may be evanescent, in which case we have a unilocular ovary with a central placenta (fig. 79); and when the leaves forming the ovaria are scarcely folded, but nearly plane, the placentiferous margins touching respectively the margins of the next ovaria, an unilocular syncarpous ovary is produced (fig. 80), having the placenta parietal, or exhibiting longitudinal lines on the interior surface. In a compound ovary, when the margin of the folded carpel is rolled inwards a little way, so that each ovary is almost bilocular, it is evident that the placentas must be situated nearly in the centre of each division of the fruit, in which case the two placenta in each cell may either unite closely together, as in *Kalmia* or *Rhododendrum* (fig. 81); or may diverge from each other (fig. 82), as in the gourds.¹ An apocarpous ovary may be known from a syncarpous one, when there is no abortion, by the number and position of the placenta. Although in every plant a carpel is present, yet in *Cycadææ* and *Coniferaæ*, where there is neither style nor stigma, the apocarpous ovary is plane or spread open like a scale, leaving the naked ovule, on its inner surface, exposed without any covering to the pollen; and even, though very rarely, the carpel may be so modified that the ovary is abortive, and nothing is visible but the naked ovule.

The ovary is *free* or *superior* when it contracts no adherence with the calyx; or *inferior*, and then it is syncarpous, and the tube of the calyx adheres with it. But the individual ovaria may be placed inside the tube of the calyx without being united with a syncarpous ovary, as in the roses, when they are said to be *parietal*. Between an inferior ovary and ovaries parietal it is sometimes difficult to draw a distinction; for when there is only one series of the latter, they may project so far towards the axis of the fruit as nearly to meet each other, and thus resemble a syncarpous ovary. But the difficulty is diminished by considering that, in a true inferior ovary, each carpel must so touch the calyx as to represent a syncarpous ovary seated within the tube. Each carpel must therefore unite laterally with its contiguous one, and at the same time all must be united at the axis of the ovary, so that there must result from the union one compound pistil. A compound pistil ought thus to indicate an inferior ovary. On the contrary, a separation of pistilla will always be accompanied with parietal ovaries (as in the rose and apple); and to these rules there is, we believe, no deviation. An apparent one is in that section of the genus *Rosa* called *systylæ*, as in the Ayrshire rose, and another in *Cratægus monogyna*, in both of which the styles unite into one; but even here a slight dissection of the ovary will show that the individual carpels are not strictly united at their inner margins, and consequently that the ovaria are

Glossology.
Pl. CXIII.
Ovarium.

¹ In this tribe the sides of the carpel or leaf connecting the exterior with the centre of the compound ovary are extremely thin and inconspicuous, while the inflexed margins are remarkably well defined; hence Seringe and De Candolle have been erroneously induced to suppose that here the midrib of the constituent leaf is, by some inexplicable means, placed in the centre of the ovary.

Glossology. parietal, and the compound ovary apocarpous, or of more than one pistillum.

Pl. CXIII. The partially adherent calyx of many saxifrages has led some botanists to say of them that the ovarium is *half inferior (semi-superum)*; but from their being two pistilla, it is apocarpous. In *Umbelliferae* there is but one pistil, although two styles; and the ovary is syncarpous and inferior. To avoid confusion, it might be better to adopt the terms of syncarpous and apocarpous ovaria, and adherent or free calyx; and a combination of these will indicate the structure of the fruit.

Each simple ovarium is more or less compressed; but the usual shape of a syncarpous one is ovoid. It is, however, sometimes elongated. In most plants it is entire, but in the borage tribe and labiate plants it is deeply lobed (Pl. CXIV. fig. 118).

Ovulum.

The *ovulum*, as we have already explained, is the body borne by the placenta, and is destined to become a seed after impregnation. The position of the ovula is of great importance in determining natural affinities. When it is fixed by its base to the bottom of one of the cells of the ovarium, of which it takes the direction, it is said to be *erect*, or if it hangs from the summit of the cell it is *inverted*; but if the ovulum is attached to the middle portion of the placenta, it may have an upright direction, and is called *ascendant*, or point downwards, and is then *suspended (appensum)*; or if it appears attached by its middle, so that one half points upwards and the other half towards the base of the cell, it is called *peritropal*. By most botanists, however, the erect and ascendant ovula are confounded under one name, and the inverted and suspended are known by the term *pendulous*. Either of these may at times resemble the other by an accidental inversion, when the ovule is said to be *resupinate*. The ovulum is either sessile, or on a stalk called a *funiculus* or *podosperm* (fig. 83, *a*), and in either case the point by which the connection is formed is usually termed the base of the ovulum, and its other extremity the apex. The ovulum consists of a nucleus and two external coats; the outer of which (fig. 83, 84, and 85, each at the letter *b*) is called the *testa* or *primine sac*; and the inner, the *internal membrane*, or *secundine sac*, or the *tegmen* (fig. *ææd.c.*) The base of the *nucleus* (fig. *ææd.d*) is always incorporated with the base of the internal membrane, and their common base is attached at some points to

the testa. The junction of the three forms the *chalaza*. The *chalaza* is sometimes at the base of the testa, but is more frequently at the apex of that external covering, so that the apices of the nucleus and tegmen, though in some plants pointing to the apex of the testa, are more usually directed to its base. Close to the apex of the nucleus, and consequently at the opposite extremity from the chalaza, a small aperture or *foramen* (fig. *ææd.e*) is to be observed in both the primine and secundine sacs. This foramen (called by Mirbel *exostome* in the primine, and *endostome* in the secundine) must always be found near the base of the ovulum when the apex of the nucleus points towards that base, and at the summit of the ovulum when the apex of the nucleus points to that part; and consequently the situation of this foramen will at once indicate the internal structure of the ovulum.¹ And this is of the greatest importance, as the future embryo is now well ascertained to be so placed in the nucleus that the radicle points directly to these orifices, as do the cotyledons to the chalaza; and a means is thus given of discovering even in the ovulum the future internal arrangement of the seed. In what we have said, we have presumed the testa, tegmen, and nucleus, to be straight; but in some plants all or some of these are more or less bent or curved, in which case we may have the apex of the nucleus directed towards its base, as in the *Cruciferae* and *Chenopodiaceae*, and even the grasses; or towards the side of the testa, as in the *Leguminosae*.²

The testa is usually entire, except at the foramen, but in two known genera, *Banksia* and *Dryandra*, it opens longitudinally, leaving the tegmen exposed. The surfaces of the testas of the two collateral ovules in these plants then unite, putting on the appearance of the dissepiment of a capsule; and the two cohering ovula seem to be as one bilocular ovulum. By this means the internal membrane or tegmen becomes the external envelope of the seed.

When the apex of the nucleus is contiguous to the base of the ovulum, a connection takes place between the base of the ovulum and the base of the nucleus, by a bundle of vessels (fig. 85, *f*) called a *raphe*. This raphe is almost always on the side of the ovule next the placenta, and even the apparent exceptions to this rule tend to confirm it. Thus in the tribe to which *Euonymus* belongs, the ovules are erect, yet in some species of that genus they

¹ Brown and Mirbel term the chalaza the base, and the foramen the apex of the ovule, without regard to the point of attachment of the ovule to the placenta, which must be attended to in studying their works.

² Mirbel, as we have already stated, considers the base of the ovulum and seed as at the chalaza, and he divides seeds into *orthotropous*, *anatropous*, and *campulitropous*. The first are attached to the ovary by their base, having a perfectly regular form, and the axis is rectilinear. The *campulitropous* are also fixed to the ovary by their base, but their form is irregular, and their axis is curved, so that the two extremities meet. The *anatropous*, like the *orthotropous*, have a rectilinear axis, but they are resupinate on their funiculus, to which they adhere longitudinally, and by means of which they are attached to the ovarium at a point near their apex. These variations are explained by Mirbel, by what he denominates the *statics of developments*, or the force of expansion, or of inertness, or of contraction of the different parts of the ovulum; and he has endeavoured to show how these causes, acting either together or independently, alter or preserve the regularity of the primitive shape. Every ovulum, according to him, has at first a regular form, and the chalaza close to the hilum or funiculus; so that if the force of development be equal at all points, the regularity of shape must be preserved, but if it be greater on one side than on the other, an irregularity must ensue. In this way an equilibrium of forces must have taken place in an *orthotropous* seed, but not in the *anatropous* or *campulitropous* ones. When an ovulum tends to become *anatropous*, the chalaza or the inner extremity of the funiculus is pushed forward in a slightly oblique direction, and inverts the ovulum, so that its base is placed where its summit formerly was, and *vice versa*; a kind of resupination which is stated by Mirbel to take place in a very short time,—but notwithstanding he appears to have followed the successive changes. By this inversion the vessels of the funiculus become elongated in proportion to the length of the axis of the ovulum; and such prolongation, united laterally to the primine sac, and extending from the exostome to the chalaza, is what is termed the raphe. Three characters distinguish the ovule destined to become in maturity a *campulitropous* seed: the indissoluble union of the hilum and the chalaza; the great force of development of one of the sides of the ovule; and the inertness or even contraction of the opposite side, which remains stationary, or even diminishes, while the other elongates. Had this last side been free in its development, it would have elongated in a straight line; but it is constrained by the inertness or contraction of the opposite one, and can therefore only increase by turning round the other as a centre. From this arises that annular form which most of the *campulitropous* seeds possess; and hence also, in all curved seeds, the chalaza ought to be constantly opposite to the hilum, and the foramen at the opposite extremity. Although all seeds may be reduced to these three types, yet by their development being stopped before the ovulum attains to the perfection of the type, and from similar results arising sometimes from different causes, many anomalies may be expected. Several have been pointed out by Mirbel himself. Thus, in the pea, the young ovule exhibits the *anatropous* form; but afterwards the raphe remains stationary, while the opposite side expands, and the seed appears *campulitropous*, but with a raphe.

Glossology. appear suspended, and then have the raphe turned away from the placenta; but if we consider a moment, we shall see, that such may arise not only from their naturally hanging down, but by an erect ovule being as it were pushed over by some peculiar formation of the plant, and thus become resupinate. But a naturally erect ovule become resupinate, must have the part that was formerly next the placenta now turned away from it; and in the same way a naturally pendulous ovule must also, when resupinate, have its raphe turned away from the placenta; and thus we may conclude, when such is the position of the raphe, that the ovule is resupinate, and that the opposite apparent direction is the true one, whether erect or pendulous. This may readily be seen in the genus *Penæa*.

It was till lately generally supposed that the *aura pollinaris*, molleculæ of pollen, or by whatever other name the vivifying influence might be called, after being absorbed by the stigma and transmitted through the style, entered the ovulum at its base, either directly or by means of the funiculus. The discoveries of Brown and others have however now proved satisfactorily that the entrance takes place by the foramens; and Brongniart has ascertained, that in many, if not in all plants, at the moment of impregnation, a slender tube or filament is protruded through the orifices from the apex of the nucleus, for the more ready absorption of the pollen granules, but which, after having served the intended purpose, withers away, leaving only a small projection or papilla, which nearly closes up the foramens. Until, therefore, it was decided that the pollen had not access to the nucleus by the funiculus, but by the foramen, the idea of a naked ovule was inadmissible, and many ingenious but erroneous hypotheses were made to explain the fruit of the pine, &c. in which an exposed ovulum exists.

But the nucleus is itself a compound body, and consists of two parts. The one is a parenchymatous or loose cellular substance, called by Malpighi the *chorion* (fig. 85, *g*); and this again includes a little vesicle or cellular bag (fig. 85, *h*) termed by the same author the *amnios*, originally filled with a mucilaginous fluid, called the *liquor amnios*. It is in the interior of this bag that the embryo is formed. As the phrases *chorion* and *amnios*, having reference to animals, are objectionable, the former has now been termed the *parenchyma of the nucleus*, and the latter the *embryonic sac*. In some plants this parenchyma occupies the great part of the nucleus, but in others it is reduced to a thin transparent membrane, under which the sac lies.¹

To complete our account of the ovulum, of which we have been obliged to explain the anatomical structure, in order to lay the foundation of a correct knowledge of the parts of the seed, we have further to say, that in many, but not in all plants, a tubular prolongation (fig. 85, *h*) of the embryonic sac takes place about the time of impregnation, from that extremity of it which is next the base of the nucleus, extending to that base, and connecting it with the sac. This is very conspicuous in the almond and yellow water-lily. Malpighi named it the *vas umbilicale*; and Gærtner viewed it as a continuation of the vessels of the umbilicus, but erroneously, as it is extremely doubtful if in any case its connection with the base of the nucleus is completed until the embryo, after fecundation, requires a considerable degree of nourishment.

Fruit.

Fecundation having taken place, the floral envelopes usually fade away, the stamens disappear, and the pistillum begins to increase in size and become the *fruit*. Although the style and stigma, having fulfilled their functions, are now nearly obliterated, the fruit ought always to show some traces of them on its surface, whenever they were seen on the ovarium. In *Cycadæa* and *Coniferæ*, where the ovulum is exposed to the immediate action of the pollen, there is neither style nor stigma upon the scale or open ovary, so neither is there on the fruit, indicating the existence of naked seeds; but the grains of corn and wheat and other grasses, having the remains of a style, are true fruits; the supposed naked seeds of the borage tribe and labiatae are for the same reason parts of a fruit. As the pistillum advances towards maturity, many alterations take place, in consequence of abortion, non-development, obliteration, or even union of parts. Thus a compound pistil having a compound or syncarpous ovary, may have a fruit of but one cell, as the hazel-nut; or a solitary pistil may, by the involution and divarication of its placentas, change into a fruit with several cells; or the placenta itself may expand horizontally, dividing one true cell into several spurious ones. In all cases, however, the contrasting the structure of the pistil with that of the fruit will materially aid us in our investigations.

The *base* of the fruit (fig. 86, *a*) is the part where it is joined to the peduncle. The *apex* (fig. 86, *b*) is where the remains of the style are found.

The portion of the pistil called the ovarium is in the ripe fruit termed the *pericarp*; it is sometimes extremely thin, as in the grasses, the borage tribe, the *Compositæ*, &c. but is often extremely thick, and even fleshy. As the leaf of a plant has an upper and under surface, and an intermediate parenchyma in which the nerves are placed, so the pericarp consists likewise of three portions: the outer coating, which often determines the form of the fruit, called the *epicarp* (fig. 87, *b*); the inner lining or the *endocarp* (fig. 87, *d*); and the parenchymatous or fleshy substance between these (fig. 87, *c*), termed the *sarcocarp* or *mesocarp*. When the ovary is inferior, or united with the tube of the calyx, as in the apple, the epicarp becomes confounded with the tube (fig. 87, *a*), and then the sarcocarp may be readily taken for the parenchyma of the calyx; but in peaches and other fleshy fruits not adherent to the calyx, it is the sarcocarp that constitutes the flesh. The endocarp is usually a mere membrane, but it sometimes is incorporated with a portion of the sarcocarp; and when this portion becomes hard and osseous, it constitutes what is called a *putamen* (when it contains but one seed), or *nucules nucula* (when they contain several seeds). As an ovary may be apocarpous or syncarpous, so also may be the pericarp. It is therefore said to be *unilocular* (fig. 104 and 105) when there is one cell, and *bi-, tri-* (fig. 88), or *multilocular*, according to the number of cells. These *loculi* or cells are separated from each other by *dissepiments*. By reverting to what has been said about the ovarium, we shall easily perceive that true dissepiments can only be formed in one way. Two contiguous portions of the endocarp are projected into the interior of the pericarp, and are agglutinated together by the parenchyma of the primary leaf, now the sarcocarp.

¹ Mirbel takes rather a different view of the subject: he considers the nucleus as a mere envelope, terms it the *torcine*, and states that it incloses two others,—the *quartine*, which appears to be attached to the summit of the cavity, and that containing the *quintine*, or embryonic sac, the last envelope, and adhering at both extremities to the quartine. But each of these parts, if they do exist, has not been seen in every ovule; and in those in which they have been observed, they are not all visible at one time, but in succession: when the first is most evident, the last are merely rudimentary; and when the latter are developed, the former are scarcely distinguishable. Mirbel even points out five distinct periods of development.

Glossology. The dissepiment is thus always of two membranes, which must contain between them vessels and nerves; and these again will point out the former junction of the two membranes, even although, by the sarcocarp drying up, they should have lost their adherence, and have separated from each other. Dissepiments may be *complete* when they extend from the base of the epicarp to its apex, and *incomplete* when they permit two contiguous cells to communicate with each other. In the thorn-apple (*Datura stramonium*) there appears at first sight to be four dissepiments, two complete and two incomplete; but in reality in this plant there are only two, curiously modified.

The axis of the fruit is that round which the constituting carpels are placed. It is sometimes not apparent. When it actually exists it is usually termed a *columella*, as in *Euphorbia*, *Lavatera*, &c.; but when two mericarps are united together it is called the *commissura* (fig. 92).

As seeds are inclosed in the pericarp, it is essentially necessary that they, after maturity, have the means of escaping. Sometimes, however, the pericarp does not open naturally, but is either split by the process of germination, or rots away by the action of the soil or of the atmosphere. It is then said to be *indehiscent*, as in the grasses, *Compositæ*, &c. But usually it splits open, and is then *dehiscent*; and the pieces into which it divides are termed *valves*. In some the dehiscence is incomplete, as in *Antirrhinum* (fig. 89), where it is indicated by two pores at the apex, and in many *Caryophyllæ* (fig. 90), where the valves only separate at the apex into teeth. The pericarp is said to be *uni*-, *bi*-, or *multivalved*, as there are one, two, or many valves. When a fruit is in its simplest state, or formed by the transformation of one carpellary leaf (Plate CXIV. fig. 104), there may be two sutures or lines by which it may open. The one is (*a*) where the margins of the leaf or the placenta meet, and this is called the *ventral suture*; the other, or the *dorsal suture* (*b*), is at the part corresponding to the midrib of the leaf. But, in a compound fruit, an opening may also take place at the junction of any two carpels; and from these considerations the various kinds of dehiscence may be explained. If the line of opening corresponds with the junction of the carpels, the dehiscence is *septicidal* (fig. 91); so that where there are dissepiments, these are divided each into their two constituent membranes, and the cells remain closed at the back; or the valves were formerly said to be alternate with the dissepiments, or to have their margins turned inwards. If the opening is by the dorsal suture of each carpel, the dehiscence is *loculicidal* (fig. 86 and 88); so that here the dissepiments do not divide into two portions, but the cells are opened at the back, or the dissepiments were said to be opposite to the valves, or the valves to bear septa in their middle. In some plants the cells remain closed, and separate in that state from the axis, which is then an extension of the peduncle (fig. 92). In others the placentas separate from the dissepiments and adhere to the axis, while the cells open, and, with the dissepiments, separate from it (fig. 93). When the dissepiments adhere to the axis, but separate from the back of the valves or carpels, the dehiscence is said to be *septifrage* (fig. 94). When a dehiscence, instead of being vertical or longitudinal, takes place across the cells, it is called *transverse* (fig. 95), as *Anagallis*.

The shape of the pericarp may be *spherical*, or *ovate*, or *lenticular* (like a lens), or *prismatical*, which terms are easily understood. It may be *acute*, or *obtuse*, or *lobed*. When the fruit is inferior it is often crowned by the teeth of the calyx; and these teeth in many *Compositæ*, as we have already explained, are represented by a series of hairs called a *pappus*, which is either (fig. 96) *pilose*, when each hair is simple, or *plumose* (fig. 97), when each hair presents on each side

a series of finer hairs, arranged like the wings of a feather. **Glossology.** In *Valeriana* (fig. 98) the limb of the calyx is at first rolled up so as to form a circular ring on the top of the ovary, but afterwards (fig. 99) expands and elongates, and constitutes a true plumose pappus. When the tube of the calyx is filled by the seed, the pappus is said to be *sessile* (fig. 97); but when it is much attenuated at the apex beyond the seed, a kind of stalk or stipes is formed to the pappus, and it is termed *stipitate* (fig. 96), but between these there are some states that tend to weaken these as characters.

Fruits have been classified in several ways, and have received various designations. From what we have already said of the ovarium, we trust the following division may be easily understood. A fruit is either simple, multiple, compound, or aggregated.

It is *simple* when it is the maturation of a single carpellary leaf. Fruits of this class may be either *indehiscent* or *dehiscent*. Of the former is, 1. the *caryopsis*, where the pericarp is very thin and membranous, and so closely united to the solitary seed as not to be distinguished as a separate body, as in the wheat and barley (Plate CXIII. fig. 100): 2. an *utricle* is similar to the caryopsis, the pericarp being membranous, but it has no adherence with the seed: 3. an *achenium* is also one-seeded, but here (fig. 101) the pericarp is hard and bony, as well as distinct from the proper covering of the seed, as in the *Compositæ* (these three are often confounded): 4. a *samara* (fig. 102) is a coriaceous, membranous, very compressed, few-seeded, indehiscent fruit, that is often prolonged laterally or at the apex into wings or appendages, but this kind does not perhaps exist in nature in an uncombined state: 5. a *drupe* is a fleshy nut inclosing a putamen, as the cherry and peach: 6. a *nut* (*nux*), in its strictest sense, as now adopted by Richard and De Candolle, differs slightly from a drupe; it contains a putamen, but the sarcocarp (then called *nau-cum*) is coriaceous instead of being fleshy. The dry dehiscent fruits are, 7. the *follicle* (fig. 103), or a carpel dehiscing by the ventral, and having no dorsal suture: 8. the *legume* (fig. 104), having both ventral and dorsal sutures, by either of which, or by both or neither, it may dehisce; rarely the sides fall off, leaving nothing but the sutures, which then form a kind of frame called *replum*. The legume is, strictly speaking, unilocular, but in some plants appears bilocular, from an inflexion of the ventral suture (fig. 105). In some instances it is separated into several parts by horizontal partitions (fig. 106) arising out of the placenta, or by contractions of the legume itself, as in *Hippocrepis* or *Scorpiurus* (fig. 107), at which it falls into pieces, when it is said to be *lomentaceous*.

A fruit is *multiple* when the ovarium is apocarpous. It has more than one style, and is formed of more than one carpellary leaf in the same flower. The carpels may be either at a distance from each other or slightly connected, but the endocarp does not separate from the epicarp to form dissepiments. Few individual names have been given to this kind, botanists having usually contented themselves with saying that it is *composed of achenia, drupes*, &c. according to the structure of each individual carpel. When these are arranged upon or round a real or imaginary axis, the fruit has been by some called, 9. *eterion*; the strawberry (fig. 108), bramble, ranunculus, anona, and peony, are examples. 10. The *ponum* or *melonida* also belongs to this class; here the fruit is crowned by the teeth of the calyx, and is formed of several parietal carpella attached to the interior of the tube by the intervention of a usually thick and fleshy expansion of the torus. Of this there are three varieties. 1st, When the numerous achenia are attached to the slightly fleshy calyx, the fruit is a *hip* or *cynarrhodon* (fig. 109), as the rose. 2d, When the calyx of the hip does not become

Glossology. fleshy, as in the agrimony, the fruit is called *amalthæa*. The third variety is the *apple* or *pomum* (Plate CXIII. fig. 87), in which there is but one longitudinal series of carpels attached to a very fleshy calyx, and so enlarged as to appear to meet in the axis of the fruit. A pomum, then, at first sight seems to be the maturation of one inferior plurilocular, instead of several parietal ovaria.

Pl. CXIV.

A compound fruit is derived from a syncarpous ovarium, and is formed by the union of several carpellary leaves. In *Ranunculus*, and other plants with apocarpous ovaries, more than one series of carpella are often matured. This, however, happens rarely among the syncarpous, but it sometimes occurs; thus, in *Nicotiana multivalvis*, where the fruit is a capsule, two rows of carpellary leaves are united into one pistillum. 11. A capsule (Plate CXIII. fig. 89 and 90) is a dry, dehiscent pericarp, usually many-celled; but may, by the placenta being parietal, or by the disappearance of the dissepiments, be occasionally one-celled. 12. When a capsule opens transversely, it is called a *pyxidium* (fig. 95). 13. When a capsule bursts into achenia, it is termed a *di-, tri-, or polakenium*. 14. When the tube of the calyx adheres to one of this last kind, the fruit is called *cremocarpium* (fig. 92), as in the *Umbelliferae*; and each of the two constituent parts (*a*) a *mericarpium*. 15. When a capsule is composed of *cocci*, or cells that open elastically by a membranous spring placed at the bottom, it sometimes has got the name of *elaterium* or *regma*, as in *Euphorbia*. 16. A *siliqua* when long and narrow (fig. 110), and *silicula* when so short as to be almost as broad as long (fig. 111), is a dry pericarp formed of four carpels, the placenta of which are parietal: moreover, the stigmas and placenta of an opposite pair of these carpels are abortive, so that the carpels themselves represent valves, while the two other intermediate carpels are contracted, and project, from the inner side of each placenta, a membrane, which unites at the centre of the fruit to the corresponding opposite membrane, the four membranes being ultimately united into one dissepimental membranous expansion.¹ In common language, then, a *siliqua* or *silicula* may be defined to be a dry, dehiscent, two-valved fruit, in which the seeds are attached to placenta situated at the sutures of the valves, and which is usually divided into two loculi or cells by a false dissepiment or prolongation of the placenta, that is parallel to the valves. After the valves have fallen, the placenta often remain, with or without the dissepiment or septum, in the form of a replum. 17. When two samara are applied to each other so closely that there appears but one (fig. 115), as in the ash and elm (the compound nature of the fruit, however, being still evident from the double stigma even when one of the cells is abortive), the fruit is still commonly called a *samara*; but in *Acer*, where the constituent parts are readily distinguished, the fruit is said to consist of two *samaroid* carpels. 18. A *carcerulus* (fig. 116) is dry and indehiscent, with several cells and seeds, as the lime tree. 19. A *gland* is a dry, bony, indehiscent, one-celled and one-seeded fruit, but always the result of an ovarium with several cells and several seeds. The pericarp unites closely to the seed, and is inclosed more or less in a sort of involucre. This term is sometimes restricted to the case where the involucre or cup is coriaceous and scaly, as in the acorn; and when it is foliaceous, as in the hazel, it is called a *nucula*. Many botanists apply to both of these the name *nut* or *nux*. When the involucre is entirely wanting, and

the fruit is borne on a fleshy support, it has been termed *Glossology*. a *xyloidium* (fig. 117), as in the cashew-nut. 20. A *microbasis* (fig. 118) applies to the fruit of the *Labiata* and *Borraginæ*. Here it is tetraspermous or four-sided, and appears to be quadrilocular; and each division, resembling a distinct achenium, is placed around the slender base of the style; in reality, however, it is a bilocular fruit, each cell being divided by a spurious dissepiment into two, each one seeded, that in general easily separate from each other. 21. In a *sarcobase* (fig. 119) the ovary is syncarpous, or of one pistillum; but all the carpels appear distinct, and are borne on the fleshy base of the compound style, as in the *Ochnaceæ*. 22. A *nuculanum* is a fleshy fruit, not adherent to the tube of the calyx, and including several distinct putamens or nuckles. 23. An *osteocarpium* is a superior fleshy fruit, with several cells, the sarcocarp being bony. 24. The *balausta* is a somewhat coriaceous, plurilocular, polyspermous, inferior fruit, adherent with the calyx and crowned with its teeth, as in the pomegranate and myrtle. 25. A *berry* (*bacca*) is a succulent fruit, with a membranous pericarp, the seeds of which lose their adhesion when ripe, and lie loose in pulp, as the gooseberry or grape (fig. 120). 26. The *orange* or *hesperidium* is a multilocular succulent fruit, similar to a berry, but having the epicarp, sarcocarp, and endocarp well defined, and forming a leathery pericarp. The loculi or cells are filled with pulpy bags or vesicles, which are mere cellular extensions of the sides of the carpella. 27. A *pepo* or *peponida* is a fleshy inferior fruit, either indehiscent or bursting irregularly, and consisting of about three carpels, each of which is divided into two loculi by its placentiferous margin (Plate CXIII. fig. 82) being so introflexed as to reach the dorsal suture. The sides of the carpel, and even sometimes the introflexed portion, usually disappear in the ripe fruit; so that at first sight it would be said to be, and has been so described, a one-celled, fleshy, indehiscent fruit, with parietal placentas that send out sometimes false dissepiments towards the axis (fig. 121), as the cucumber and gourd. We do not agree with Richard in calling the fruit of the *Nymphaea* or *Nuphar* a peponida. In these there is in fact an apocarpous ovarium (fig. 122), each carpel being merely attached by its back to an expansion of the torus, which soon decays, leaving the carpels distinct from each other. The torus also surrounding the styles and the stigmas, makes the whole assume the false appearance of one pistillum; and that part of each carpel which is directed towards the axis of the fruit is the placenta, and not a dissepiment. There is, therefore, little or no difference between the *Nymphaeaceæ* and *Nelumbo-naceæ*, except that the carpels of the latter are monospermous. The fruit of *Hydrocharideæ* resembles in some degree a peponida; it is one-celled, and the placentas are truly parietal, but project from the false dissepiments towards the axis, appearing sometimes as if a many-celled fruit.

Aggregated fruits are formed out of several flowers. 28. An *amentum* or *catkin* exists in those plants to which there is no floral envelope; but in place of it there is a membranous bractea situated below each pistillum, as in the *Salix* or willow. 29. When the bractea of an amentum becomes extremely small, and the carpellary leaf is a large indurated scale, open at all periods of its growth, and containing naked seeds, we have a *cone* or *strobilus* (fig. 123), as in the pine tribe; and when this is much re-

¹ If *a', a', a', a'*, in fig. 112, be four carpels with parietal placenta and ovules (*U', U', U', U'*, *b, b, b, b*), and if *c', c', c', c'*, be the stigmas to each, then if *c', c', U', U', U', U'*, be abortive or disappear, we shall have the appearance in fig. 113; and if, in addition, the placenta *b, b, b, b*, project a membrane into the centre of the fruit, when these membranes unite we shall have the section of a *siliqua* or *silicula*, as in fig. 114.

Glossology. duced in size, and the scales firmly cohere, it is called a *galbulum* (fig. 124), as in *Thuja*. The term *cone* is also often applied to the fruit of some *Proteaceæ*; but in these there is a perianth, and the indurated scales are real bractes, and it may be sufficient to say of their flowers that they are aggregated. 30. The *sorosis* (fig. 125) is when several fruits (*b*) are united together into one body by the intervention and combination of their respective fleshy and highly developed floral envelopes (*a*), as in the mulberry and pine-apple. 31. The *syconus* or *fig* is when the fruit is composed of many small drupes or achenia, collected on the interior of a fleshy and succulent receptacle formed by the hollow dilated apex of the peduncle. Each of the achenia belongs to a distinct floret, and therefore, when the fig is expanded into a nearly flat disc, as in *Dorstenia*, it resembles the receptacle of the *Compositæ*, and is therefore scarcely entitled to be considered as a peculiar fruit.

Placenta.

Having thus given a rapid sketch of the different kinds of fruits, we must now revert to the carpel, of which they are composed; and we would again recall to the recollection of our readers, that this is a modification of a folded leaf, towards the margins of which, arising from the extremity of the nerves, are placed the seeds. The parts to which these are attached must therefore always be two (however closely they may be approximated) in each carpel; they are immediately connected with the style, and usually of a different texture from the rest of the cell; and, as has been explained while describing the ovary, they are generally called *placentæ*, though by some denominated *trophosperms*. In a solitary carpel the placenta is usually at the ventral suture, but, by the margins being occasionally introflexed, may be either in the centre of the fruit, or even at the dorsal suture; and therefore, in a plurilocular pericarp, it may be either at the axis of the fruit, or in the middle of each cell, or, when each cell is spuriously bilocular, may be even at the dorsal sutures; a one-celled pericarp, that is formed from a syncarpous ovary, must however have the placentas strictly parietal, and placed at the margins of each carpel. A plurilocular pericarp may present an anomalous appearance by abortion. Thus there may be a central placenta by the disappearance of the sides of the carpels, or the placenta may be parietal (or rather at the dorsal suture), by the abortion of the sides and introflexed margins. On the other hand, an unilocular fruit may appear bi- or multilocular, by the placenta projecting membranous expansions or spurious dissepiments, all which must be carefully studied while pronouncing on the affinities of different plants.

Sometimes the placenta presents small prolongations, to which the seeds are fixed, and which are termed *funiculi* or *podosperms* (fig. 127, *a*). They are very evident in leguminous plants (fig. 104), in *Cruciferae* (fig. 110), and many others. In some they are very short and thick, but are in others slender and filiform. When the placenta or the funiculus expands at its point of attachment to the seed into a cup-shaped body of greater or less dimensions, this is termed an *arillus*. In the nutmeg (fig. 126) this arillus is red and fleshy, and cut unequally, and is called a mace. In *Euonymus* it covers the seed nearly all round (fig. 127); in *Polygala* it constitutes a little crown scarcely visible, at the base of the seed. But arillæ must not be confounded with integument of the seed. Thus the apparent appendage of the seed in *Nepenthes* (fig. 128), and the fleshy covering in the jasmine, are actually portions of the testa. An arillus is never developed till after the impregnation of the ovulum.

Seed.

The fruit is formed of two parts, the pericarp and the seed. What we have already gone over belongs to the former; we now proceed to the latter.

The *seed* is that part of a perfect fruit which is found in the internal part of the pericarp, attached to the placenta, or to its process, the funiculus. Every seed arises from a fecundated ovule, and therefore a naked seed can only be said to exist in those rare cases in which we have found a naked ovulum. Its essential character is to include an organized body, which, under favourable circumstances, is developed, and becomes a plant similar to that from which the seed was obtained. This body is called the *embryo*.

The position of the seed is of equal importance with that of the ovule; but as the terms are the same, we will not here repeat them.

In the ripe seed, what was the base of the ovulum becomes the base of the seed, and is called the *hilum* or *umbilicus*; the expansion of the raphe at the base of the nucleus becomes the *chalaza*; and the foramen is then called the *micropyle* (fig. 129, *a*). The *testa* (fig. 130, *a*) or primine sac sometimes disappears, and in others becomes thick; the *tegmen* (fig. 130, *b*) becomes usually incorporated with the testa, although it also in some plants disappears, and the two are generally known under the name of *episperm*. De Candolle has, without considering the ovule, but only regarding the ripe seed, followed Richard, and viewed the episperm as but one coat, the outer surface of which he has termed the *spermoderm*, the inner, the *endopleura*, and the intermediate portion, chiefly constituted by the spreading vessels of the raphe, the *mesosperm*. But the terms testa, tegmen, and raphe, are much less exceptionable, as they exhibit a relation to the structure of the ovulum. In some plants, as we have already said, the testa is fleshy; in others it is attenuated (fig. 128) into a long process, both of which may be mistaken for an arillus if proper attention be not paid. In the cotton-plant the whole surface is covered with hair-like expansions, when the seed is said to be wrapt in wool; or such hairs may be merely placed at one or both ends, when they constitute a *coma*. In some plants there are tumours on the testa, near the hilum, or at its opposite end, called *strophilæ* or *carunculae* (fig. 131), the precise nature of which is unknown; but in some instances they appear to be dilata-tions of the chalaza, and in other cases they seem caused by a diseased state of the lips of the foramen or micropyle.

After impregnation, the nucleus undergoes great changes. The embryonic sac increases rapidly in every way, and often pushes back the cellular tissue or parenchyma of the nucleus, until this latter is reduced to a thin pellicle or membrane, and is ultimately filled with nothing but the embryo; in which case the membrane or sac itself either disappears entirely, or becomes incorporated with the parenchyma of the nucleus; and such plants are said to be destitute of *albumen*. In others, however, numerous globules are deposited on the inside of the sac, and these by their agglomeration constitute the *endosperm* (fig. 130, *c*), inclosed in which is the embryo (fig. 130, *d*). But the almost complete destruction of the parenchyma of the nucleus, and great development of the embryonic sac, does not always take place: for in some plants the sac is only enlarged sufficiently to contain the embryo, and the parenchyma is to be observed (fig. 130, *e*) in the ripe seed filled with globules of a starchy substance, and is thus converted into a body similar to the endosperm; but, from its different situation and mode of formation, is called by another name in order to distinguish it, viz. the *perisperm*. In a few plants both the endosperm and perisperm may be traced, as in the water-

ossology. lily. We adopt these terms in conformity with Brongniart; but we must observe that systematic writers use these words, as well as albumen, promiscuously. In common language these are applied to that body which is to be sometimes found between the embryo and the coats of the seed, and whose cellular substance is totally different from the organized embryo; but when botanists discovered, as in the water-lily, in the *Scitamineæ*, *Piperaceæ*, and some other tribes (fig. 132), not only the albumen, but a second body more immediately surrounding the embryo, they gave this the name of *vitellus* (Brown), or *sac to the embryo* (Lindley). Brown, however, afterwards showed that the vitellus was a kind of albumen, and that two kinds might exist in the same plant; and more lately Brongniart has suggested the propriety of employing expressions for each. Perhaps, on the whole, the term albumen, so generally adopted, might be used promiscuously for whichever is developed, and when it is necessary to distinguish both, to employ the terms endosperm and perisperm. We object to the use of the phrases vitellus, and sac to the embryo, because in many instances the albumen is entirely formed of this supposed sac or vitellus, and that if these words are to be adopted, they ought to be so constantly, and not in those cases only where both parts of the albumen are visible.¹

albumen. The nature of the albumen is of great importance: it is *farinaceous* in the grasses; *coriaceous* and almost *cartilaginous* in many umbelliferæ; *ruminated* when it is wrinkled by reason of prolongations of the coat of the seed into the folds of the albumen, as in the *Annonaceæ*; fleshy in most of the *Euphorbiaceæ*; *horny*, as in the coffee-bean; or thin and membranous, as in many *Labiataæ*.

Embryo. The embryo, as we have already said, is that organized body existing in the perfect seed after fecundation, which is destined to become a plant similar in all respects to the parent. It may either have or be without an albumen. When the albumen is present, and the embryo is applied to a point on its surface, it is said to be *external* (*exterior*); or if rolled round it, is *peripheric*. If shut up within the albumen, it is said to be *inclosed* (*inclusus*), and then may be either in the centre of the albumen (*centralis*), or not in the centre (*eccentricus*). Usually there is but one embryo in each seed; but plants occur in which there are more than one, as the *Allium fragrans*, mistletoe (fig. 133), &c.

As the embryo is already organized in the seed, and becomes a plant by mere development, so all the parts of the future plant must exist in it, although in a mere rudimentary state. It must, therefore, contain the rudiments of the root, of the stem, and of the leaves.

Radicle. This is the rudiment of the root (fig. 134, a), and by germination becomes a root. Such may either happen by the mere elongation of the exposed radicle, or by its bursting through a peculiar envelope, and protruding the root from within. Plants which have this cover to the radicle are termed *endorhizæ* (fig. 135, a), and those which

have none *exorhizæ*. Moreover, with very few exceptions, all exogenous plants are *Exorhizæ*, and the endogenous, *Endorhizæ*; so that the radicle indicates the future structure of the stem. The radicle is usually quite distinct from the albumen; but in *Cycadeæ* and *Coniferæ* there is an organic connection between them. Hence Richard has raised these orders to a distinct class, and called them *synorhizæ*.

The *neck* or *collum* is the line of separation between the radicle and the portion above it.

The *Plumule* (fig. 134, c), is what is destined to become the stem, and is therefore a rudimentary leaf-bud. It is by some divided into the *cauliculus*, or the portion between the radicle and the cotyledons, and the *gemma*, or that which is situated above the cotyledons. If, however, our idea of the plumule be correct, the cauliculus corresponds to the neck or collum, while the gemma is all that constitutes the true plumule. The plumule is often undistinguishable from the cotyledons, as in most of the exogenous plants that have albumen; while it is pretty evident in all exogenæ without albumen. Among the endogenæ the plumule is frequently rolled up in the cotyledon, and is not observable till after germination.

The *cotyledons* (fig. 134, b) are the primordial leaves of the plant; and as the plumule corresponds to a leaf-bud, so the cotyledons must be lateral, and situated at its base. We have already observed that in exogenæ the leaves towards the bottom of the plant have a tendency to be opposite, and in endogenæ alternate. In the embryo, then, where there can be but few leaves, we may naturally expect this disposition to be exact; and in fact it is so, exogenæ having opposite or verticillate cotyledons, and endogenæ alternate. In the former case they are usually two in number, whence exogenous plants are also called *dicotyledonous*; but sometimes there are more than two, as in the pine. These, however, being in a whorl, are mere modifications of the opposite cotyledons; and it has not been thought necessary to distinguish them from the dicotyledonous. When the cotyledons alternate, it is obvious that one only can be present at the base of the plumule; hence endogenous plants are called *monocotyledonous*. In some of these the first leaf of the plumule is at the same time slightly developed, whence botanists have supposed that some endogenæ have two cotyledons. Their alternating with each other will, however, completely distinguish them from the dicotyledonous plants. Sometimes the two cotyledons of the exogenæ are consolidated into one piece, as in *Lecythus*; in other plants, in which the leaves are reduced to mere scales, the cotyledons are also in a reduced state, and scarcely perceptible; but we have no right to infer, as some have done, that the embryo has none at all, or is acotyledonous. The cotyledons are erect, and placed close to each other, containing between them the plumule; they may be *fleshy* or *foliaceous*, *narrow* and *semicylindrical*, or *broad* and

¹ We have already stated Mirbel's view of the structure of the ovulum, and said that he has pointed out five distinct periods of development. In the first, the ovulum is scarcely perceptible, being a small pulpy conical substance, without a foramen. In the second, the exostome and endostome open, and they are to be perceived dilating insensibly until they have attained their maximum. The primine and secundine are manifest, as is also the terecine; but this only puts on the appearance of a round or conical cellular mass, of which the apex protrudes beyond the secundine. In the third period the primine and secundine, united together, increase much in size, have their double orifice closed, and consequently conceal the terecine, which becomes a membranous bag. In the fourth period the quartine arises from the internal surface of the nucleus, and the quintine is elongated into a narrow utricle attached by the one extremity to the point corresponding to the chalaza, and by the other to that near to the endostome. This is the period in which the ovule passes into the state of a seed. In the fifth period the quintine expands, the embryo exhibits the cotyledons as well as the radicle, and reaches its full size; and the substance of the albumen is formed either in the cells of the quintine, or in those of the quartine or terecine, when it is no longer possible to recognise the different envelopes of the ovule. These considerations of Mirbel, though apparently different, are in reality much the same as those of Brongniart, the quartine corresponding to the parenchyma of the embryo, and the quintine to the embryonic sac.

Glossology. *flat*; they may be *plane*, or *plicate*, or *conduplicate* (fig. 136), as in the cabbage, or *convolute* (fig. 139) or *wrinkled*; they may be *entire*, or *lobed*, or *divided*. They are said to be *hypogeous* when they remain under ground during germination; or *epigeous*, when, by an elongation of the collum, they rise out of the ground during that process, as in the bean.

Pl. CXIV.

Having thus explained these parts, we have to notice the direction of the embryo. It may be *straight* or *curved*. The radicle is the *base* of the embryo, and the summit of the cotyledon the *apex*. Now, as the hilum is the base of the seed, so, when the radicle points towards the hilum, the embryo has the same direction as the seed, and is said to be *homotropous*, and if at the same time it be straight, *orthotropous*; and when the cotyledons point to the hilum, it is inverted, or is called *antitropous*. When it assumes a horizontal direction, or lies across the seed, and has not the same direction with it, it is *heterotropous*. And, lastly, in a curved seed, both extremities of the embryo may be turned towards the hilum, and it has been then termed *amphitropous* (fig. 140); but this is a modification of the antitropous. It has been now discovered that the radicle, or base of the embryo, is always situated at the foramen of the ovule or micropyle of the seed, and that the other or cotyledonary extremity as invariably is directed towards the chalaza. If, then, the nucleus of the ovule have a contrary direction to the ovule itself, or if the micropyle be near the hilum, the embryo is homotropous; but if the nucleus be erect, or the micropyle be at the apex of the seed, it is antitropous; and if the micropyle be at the side of the seed, it is heterotropous. In a curved seed, where the micropyle and chalaza are brought nearly into contact, we have the amphitropous embryo.¹

The position of the hilum in regard to the radicle, or, as one may say, the direction of the embryo with respect to the seed, is called the *spermic* direction of the embryo, and is usually of great importance in defining most natural groups. Thus, in the horse-chestnut, where there are two seeds in each cell, of which the one is erect and the other inverted, or rather resupinate, the spermic direction of the embryo is the same in each. But in some tribes, as the *Proteaceæ*, the situation of the hilum on the seed appears to be variable; in which case we must resort to the *pericarpic* direction of the embryo, or its direction relatively to the fruit; and then, when it has the same direction as the fruit, it is *erect*, or the radicle is said to be *inferior*; and when it has an opposite direction, it is *inverted*, or the radicle is superior.

In a curved embryo, the relative position of the radicle and cotyledons is of great importance. Upon this De Candolle has founded his divisions of the cruciferae. When the radicle is so bent that it touches the back of one of the cotyledons, it is said to be *dorsal*, or the cotyledons *incumbent* (fig. 137). When it is applied to the edge or cleft of the cotyledons it is *lateral*, or the cotyledons are *adscumbent* (fig. 138). The same terms are analogically applied, even when the radicle is very slightly bent, but where, by a continuation of the bend, it might touch the back or edge of the cotyledons, as in the genus *Polygonum*.

Arrangement of the Organs of Reproduction.

All the organs of reproduction being modified leaves,

it might be expected that their relative position must follow the same law; but whatever be the causes of aberration, we know that such is seldom the case. Although the number of the parts of each verticil, as the calyx, corolla, &c. be usually the same as that of the leaves of the plant, yet every sixth real leaf is placed under the first in a quinary spiral, while in the flower the general rule is, that the sixth, or the first petal, is placed between the first and the second leaf of the spiral, or, in other words, the petals usually alternate with the sepals. In the same way the stamina alternate with the petals, or are opposite to the divisions of the calyx; and, lastly, the carpels alternate with the stamina, and are opposite to the petals. Such is the general disposition when the parts of the flower are definite and present; and even although at times there be a multiplicity of stamina and styles, these arise from two or more rows of the staminary and carpellary leaves being developed, and can scarcely be said to affect the rule; and hence this is called the *normal arrangement*, and the *symmetrical number*. But exceptions nevertheless do occur. Thus petals have been found placed before sepals, stamens before the petals, or carpels before the stamens, as well as various combinations of the opposite with the alternating system; but no plant is, we believe, known in which all the parts are opposite. One of the most remarkable states is where the calyx and corolla do alternate, while the carpels are placed opposite to the sepals, and alternate with the petals. Brown, upon whom no irregularity of structure, even the most trivial, is lost, has, from these anomalies, suggested that the full or *complete number* of parts in both the stamina and the carpels is equal to that of the divisions of the calyx and corolla taken conjointly. In the monocotyledonous plants the complete number is the most prevalent, while it is rare among the dicotyledonous. The full number may, however, be seen in decandrous and octandrous plants. Most of the leguminosæ exhibit the complete number of stamens, but all the pistilla are abortive but one. Many of the genera that have the symmetrical number exhibit sometimes glands, and sometimes imperfect stamens between the perfect ones, which tend to show the extreme accuracy of Mr Brown's suggestion. In distinguishing genera, or even orders, it is often of importance to examine whether the arrangement be normal or not.

But there is another point worthy of consideration, and that is the relative position of the parts of the calyx to the axis of inflorescence, or to the subtending bractea. That part which is next the bractea is said to be *anterior* or *inferior*, while the opposite portion is *superior* or *posterior*. Now, one of the segments of the calyx is usually posterior, and a petal anterior; but in a very few groups of plants this position is reversed. When the symmetrical arrangement takes place, one of the sepals is, we believe, always superior, and it is evident that one of the carpels must be therefore anterior; and when the complete number is to be observed, one carpel must be also anterior, whatever be the situation of the sepals. But what is remarkable is, that though all the carpels be reduced by abortion to unity, the solitary simple pistillum that is left is the one which was inferior; so that in every possible case where the pistils are reduced to one carpel, that one is situated next the bractea, and consequently has its placentiferous margin, which is next the axis of the flower, superior.

¹ Mirbel takes notice of an anomaly in the *Primulaceæ* and *Plantagineæ*, arising from the unequal development of the parts of the ovule. Here the primine sac or testa, in consequence of an extraordinary increase on the extensible side of the ovule, and a gradual contraction of the opposite one, has by degrees the exostome turned towards the chalaza, so that at last, as in other curved seeds, the two extremities coalesce; but the extensible side of the secundine, and even of the terecine or nucleus, soon ceases to increase with the corresponding side of the primine; so that the embryo, of which the radicle remained close to the summit of the internal envelopes, becomes stationary with the endostome, whilst the exostome has pursued its course and does not stop till it reaches the base of the ovule.

Glossology. The examination, then, of a simple solitary pistillum will thus, although we may have before us no more than a flower without the bractea, determine the anterior and posterior situation of the lobes of the calyx or sepals. In the same way, when the division of the flower is quinary, and the carpels are reduced to two, the one is usually anterior, and the other posterior; or the solitary carpel being anterior, the addition to it is posterior. The only exception to this with which Mr Brown (who first laid any stress upon it) appears to be acquainted, was in some genera of *Dilleniaceæ*. Martius, and following him Lindley, have distinguished *Gentianeæ* from their allies by the two carpels being placed right and left, and not anterior and posterior; but perhaps these able naturalists have not taken into due consideration the nature of the inflorescence and the consequent position of the bracteas. At present, therefore, we do not consider that tribe as an exception. In *Dilleniaceæ* even, if we understand rightly the structure of the order, the apparent exceptions are caused by peculiarities upon which it were improper here to enter, nay even imprudent, for no one in Europe has had the same opportunities of studying the group as the distinguished naturalist to whom we have alluded.

With regard to the number of parts in each whorl of the flowers, the symmetrical number is *five* among the dicotyledonous, or sometimes *four*, while in the monocotyledonous it is *three*. When, however, we consider that, on the one hand, there may be a reduction of parts, by the sepals, petals, stamina, and carpels, being much subject to abortion and union, and, on the other, an excess, either by multiplication, by more series than one of the same kind being developed, or by the combination of several flowers into one, we may easily conceive how few plants belong either to pentandria pentagynia, or to pentandria monogynia with a five-celled fruit.

Some botanists have supposed that the calyx and corolla form only one envelope; but this question seemed put to rest till the complete number of stamina and styles were found each equal to the conjunct number of both the floral coverings, when we have seen it revived. But we would suggest to those who may be inclined to adopt such an opinion, the difficulty of the case when petals are placed before the sepals. If these formed one envelope, then we must suppose the alternating petals abortive, and the apparent one a transformed stamen; and this supposition might be true if we *never* found a real stamen also opposite to the sepal and petal; but the *Berberideæ* form at once an exception. We are aware that such a difficulty might be partly overcome by viewing the calyx of the *Berberideæ* as a series of bracteolæ, so that we should have but one floral covering, and thus approach them to the *Laurineæ*; for, by the abortion of some stamens, there is nothing to prevent the others being opposite to the petal,

provided the petals were not also opposite to the sepals. **Glossology.** But we do not recollect that any one has placed the *Berberideæ* among the monochlamydeæ; and as for the theory Pl. CXV. in general, it has been permitted by common consent to be now almost forgotten.¹

CELLULAR PLANTS.

Having now at length explained the reproductive organs of vascular plants, we cannot pass over the *cellular*. In all these, as we have already said, there are no spiral vessels; and if, as we imagine, such are essential to the formation of a fecundating pollen, and of an embryo, we shall have no difficulty of denying to the whole class a real seed. Some botanists have insisted on the presence of male and female flowers; but if these do exist, they are in so very modified a state, so small, and so obscure, that all cellular plants have been invariably termed *cryptogamous* or *agamous*, in opposition to vascular plants, or those with spiral vessels in which there are flowers, and hence called *phanerogamous* or *phænogamous*, from their sexes being evident and well formed. From the imperfection of the pollen and ovula (allowing such to exist) no embryo is formed, and thus cellulares are by some called *arhizæ* (without a radicle), and by others *acotyledonous* (without cotyledons); both of these terms, however, from their allusion to an embryo, are, in our opinion, subject to criticism, so that those at one time adopted by Richard, of *embryonata* (with sexes, seeds, and embryo), and *exembryonata* (without sexes, without seeds, and without an embryo), for the two grand divisions of vegetables, are more strictly correct. But if cellular plants have no seeds, how are they reproduced? Linnæus has laid down the rule *omne vivum ex ovo*; but at that time the anatomical structure and physiology of the ovum was not so well understood; and there does not seem to be any doubt in the present day, that where spiral vessels are not present, a new individual may be formed by mere dilatation of some portion of the parent plant suited to the purpose, remotely similar to the multiplication of polypi in the animal kingdom, or even to spurious leaf-buds among vegetables. The portions thus capable of expansion have been by some termed *seeds*, from a general resemblance to true seeds, but are strictly called *sporules*. These sporules appear to give rise to a plant, in many cases, by elongating at some one point that seems to be only determined by contingent circumstances. In the ductulose cellular plants (we allude chiefly to those ferns with a rhizoma, for these alone have been examined with sufficient care) the sporule elongates into what at first has the appearance of a short club-shaped body (fig. 141) with two or three transverse darker coloured streaks. This, then, by degrees expands into a flat cellular and somewhat folia-

¹ Since the above was written, we have received a work by M. Dunal of Montpellier on the floral organs. This distinguished botanist considers that all the parts of a flower in its perfect state may be referred to three systems, which are respectively composed of several verticils or series in the following order, the divisions of each verticil constantly alternating with those of the preceding verticil. I. *Calycinal system*, and always sterile. Of this there are three verticils, the first being sometimes called exterior sepals; the second is often termed by botanists an outer calyx; the third is the calyx of authors, and within its segments, and opposite to them, and often adhering with them, are an equal number of scales or *lepalis* analogous to those in the next system, but which form only a part of this third verticil; and these scales cover the whole inside of the calyx in many achlamydeæ. II. *Male reproductive system*, or androecium. This is formed of two ranks, an exterior and interior. Of the former, the first verticil furnishes the petals, in the axils of which are found scales or *lepalis*, but both only form one series; the second verticil is of an equal number of parts, and alternate with them. The inner androecium has also two verticils. III. *Female reproductive system*, or gynoecium, consists likewise of two verticils, the first of which usually constitutes the fruit, and consequently has its divisions opposite to those of the calyx or third verticil of the calycinal system. Thus, the whole parts of the flower consist of nine series or verticils. The *lepalis* or stamens found in the axils of the petals or first verticil of the exterior androecium, as well as the real stamens, are often separated into several, or, as Dunal terms them, *choristate*, as in the almond. The fleshy disoid torus found in some plants he supposes to arise from the abortion of the inner androecium; a perigynous ring or disc, as in the *Santalaceæ*, he supposes to be formed by the union of the *lepalis* and filaments of the outer androecium. We shall not here enter into a discussion on the merits of this theory, which it is difficult to understand without a reference to M. Dunal's figures; but shall merely observe that it is exceedingly ingenious, and, if properly substantiated, may explain several anomalies in the structure of flowers hitherto involved in considerable obscurity.

Glossology.
Pl. CXV.

aceous substance (fig. 142), setting out radicular fibres from its margin; and these being now capable of deriving immediate nourishment from the earth, the body of the sporule disappears. This flat substance appears by elongation to become the rhizoma; for soon after it is fixed to the ground, it emits, from a point on its upper surface (fig. 143), a thread, which is afterwards the stipes and the leafy part of the plant. Mosses germinate nearly in the same way; the clavate, and as if articulated, body arises from the sporule, and then elongates, branches, and forms the radicular portion, from some part of which the stem (as it is called) is projected, bearing the leaves (See *Phascum serratum*, fig. 144). Many *Hepaticæ* germinate as the mosses. *Conferæ* (part of the *Algæ*) arise like the roots of mosses, and these fibres afterwards more or less unite together. Most lichens germinate like the ferns, the dilated filament becoming the frond. The *Fungi* have not been well observed in this respect; but it seems probable that, in the greater number, the whole mass is formed by the mere expansion of the sporule. How in all these orders the sporules are formed from the cells of the parent plant, and how they are endowed with the power of expansion, is a difficulty not easily solved; but this, as well as the investigation of the vivifying principle of the pollen on the embryo in vascular vegetables, is a subject purely physiological, and does not fall within our limits. We shall, however, merely state the only analogy, and it is a distant one, we can trace between these. Sporules are brought into life by coming into contact with external moisture, while the granules of pollen may be viewed as sporules that require to be fully shaped and fostered by the juices in the interior of the embryonic sac.

Equisetaceæ.

1. *Equisetaceæ*.—The stems, and often the principal branches, of this tribe, are terminated by an ovate or conical *spike*, or rather raceme (fig. 145), composed of several verticillated scales (fig. 146), which are pedicellate, peltate, and angular. From the under side of these scales several wedge-shaped *involucra* or *indusia* project downwards, and burst longitudinally on the side next the pedicel, and discharge a multitude of globules. These globules (fig. 147), when seen under the microscope, consist of a central green compact spherical body, furnished at its base with four elongated clavate filaments, slightly united by pairs of an elastic nature, so that when moist they twist spirally round the central portion, but when dry unroll and expand themselves, bearing on them many minute granules. The use of these parts is unknown. Hedwig supposed the central body to be a pistillum, and that each pair of elastic filaments formed one stamen, whose pollen was the granules. Brongniart, tracing in these plants a general resemblance to *Coniferæ* and *Cycadeæ*, presumes that the central body is a naked ovulum, and the filaments four grains of pollen united in pairs to its base. But although we admit either of these theories, we cannot regard the male organs as perfect; and the uniform structure of the supposed pistil or ovule militates against both hypotheses. Perhaps the central body may be viewed as a short seta or receptacle, analogous to that found in Ferns; the clavate filaments would then supply the place of a theca and annulus, while the minute granules would be sporules. This view is probable, if we consider each globule with the filaments as the result of a transformed frond.

Filices.

2. *Filices*.—The organs of reproduction, commonly called the *fructification*, of ferns, arise from veins either on the under surface of the frond, or at its margin. In some genera the frond, or a part of it, becomes deformed, and seems entirely covered by these organs. Each cluster of organs is called a *sorus* (fig. 148 and 149), and is sometimes protected by a membrane termed an *involucre* or

indusium (as in fig. 148), which is always attached to the veins. This indusium is said to be *plane* when it lies flat upon the sorus; or *peltate* when more or less circular, but depressed in its centre so as to form a kind of small pillar in the middle of the sorus; or *reniform* when it is the half of a peltate involucre, and thus resembling a half circle, attached by its centre on the one side of the sorus. It is *squamiform* or *scale-like* when it has the appearance of the scales of the frond. It may be *continuous* when the involucre of several sori are united into one uninterrupted line, and is *single* or *double* according as it extends from the vein on one or on both sides of the sorus. Thus a peltate involucre is double, and consists of two reniform ones. An involucre is usually *superior*, but is sometimes *inferior*, or placed under the sorus, and surrounds it. It may either open outward (*exterius dehiscens*) in an opposite direction to the midrib, or inwards (*interius dehiscens*) towards the midrib; and when it is inferior, may burst from the apex into *laciniae* or into two *valves*, or the upper part may disappear, leaving the lower cup-shaped (*involucrum pateriforme*). Sometimes the part of the vein to which the reproductive organs are attached is projected from the frond into the sorus, and is then called a *receptacle*. The sori may be fixed to the middle of a vein, or at its bifurcation, or at its extremity. They are *round*, or *linear*, or *reniform*, *distinct* or *confluent*, or *continuous*. They consist of groups of *capsules*; these, called more properly *thecæ* (fig. 149), are either pedicellate, with the stalk passing round them in the form of an elastic ring or *annulus*, or are sessile, and usually destitute of such a ring; the former are called *annulate*, the latter *exannulate*. These thecæ either burst open irregularly, or into two valves, or on the opposite side from the ring (fig. 150) when it is present. The sporules seem arranged without order in the interior. The sori may be considered as a group of fronds, the stalk of the theca as a modified stipes, the annulus as the midrib or rachis, and the theca itself as the transformed frondose portion. This highly probable view was first, we believe, suggested by Mr Lindley. Hedwig and others, who have wished to discover sexual organs among ferns, have been much puzzled, each having a different opinion, though none seems as yet worthy of notice.

3. *Marsiliaceæ*.—The fructification is situated at or very near the root or rhizoma; in one plant along the petiole of the frond or leaf. It consists of a somewhat globular *involucrum* (fig. 151 and 152), of a leathery or membranous texture. This, unlike the ferns, does not open, and is probably composed of a transformed frond, the veins of which give rise to one or more partitions; hence the involucre appears to have sometimes several cells. Attached to the veins or partitions are small bodies, apparently of two different kinds. Of these, in *Marsilea* (fig. 152), the one (fig. 153, *a*) is an oval-stalked theca, containing corpuscles, some large and roundish, others minute and angular. The other kind are very small bags filled with minute granules, and attached (fig. 153, *b*), several together, to the stalk of the theca. The theca, by the sexualists, has been considered a pistillum, and the bags as anthers. In *Pilularia* the structure is much the same, only the supposed anthers occupy the upper portion of the involucre, and the thecæ the lower. In *Salvinia* the anthers consist of grains, attached by long threads to a central column; in *Azolla* they are angular, and inserted upon a central body that occupies the upper half of the involucre, while the lower half is filled with a turbid fluid, and the thecæ are placed within a different involucre.

4. *Lycopodiaceæ*. Here the organs of reproduction are axillary or in spikes, and are composed of roundish

Glossology.
Pl. CXV.

lossology. *sules* or *thecæ*, that are from one to three celled, and one to three valved, or indehiscent; the thecæ are usually of two kinds, the one (fig. 154) containing a minute pulverulent matter (fig. 155, and magnified, fig. 156), and placed towards the upper ends of the shoots; the other (fig. 157) containing granules or corpuscles (fig. 157, a), of a much larger size, and situated on the lower parts of the shoots. In *Isoetes*, where the leaves are all radical, the outer leaves contain in their axils the granular, the inner the pulverulent organs. The pulverulent have been called by some *anthers*; the granular, *pistilla*. The latter certainly do germinate, but Willdenow asserts that the former do so likewise. Gärtner also supposes both to contain seeds or sporules, and that there is no difference of sex.

5. *Musci*. Here the organs are likewise of two kinds; the one, termed by Hedwig and many of his followers *anthers*, being cylindrical or fusiform stalked bags (fig. 158), that contain a pulverulent matter mixed with others that are empty and jointed; the other, *capsules* or *thecæ* (fig. 159, 160, 161, 162). These latter, when young, are seated on a *receptacle*, which, from its being occasionally provided at the base with several small leaves, called a *perichæcium*, may be viewed as a deformed termination of the stem or branch. This theca is protected by a more or less membranous substance, called a *calyptra* (fig. 160 a, 163 b), loose from the theca, but attached around its base to the receptacle (fig. 161 a); the calyptra has by some been considered a *style*. The capsule or theca, at first green and small, soon begins to swell, and becomes attenuated at the base (fig. 160 b, 163 c), into a *pedicel*, called a *seta*, which is often of considerable length; but in two genera, *Sphagnum* (fig. 168) and *Andræa* (fig. 161), is entirely wanting. By this attenuation of the theca, and formation of a seta, and by the increasing magnitude of the theca itself, the calyptra is torn from its attachment to the receptacle, and may be soon perceived resting on the upper part of the theca (fig. 160). When this in maturity is split up on the one side (fig. 160), it is said to be *dimidiate*, and if entire, or with several short clefts (fig. 164), *mitriform*; in some, as in *Splachnum* and its affinities, it remains entire for a considerable period, but afterwards splits and appears dimidiate, when it is difficult to say under which it ought to be arranged; but, notwithstanding, the nature of the calyptra is now acknowledged by all to be a good natural generic distinction. The surface of the calyptra may be *smooth*, or *striated*, or *sulcate* (*furrowed*), and may be *glabrous*, or *clothed* with hairs. In some polytricha there is in addition an outer hairy calyptra, but this is formed of abortive leaves entangled together, and scarcely attached to the inner and true one. Upon the removal or fall of the calyptra, the theca presents itself, sometimes *globose*, or *ovate*, or *oblong*. In some it is *straight*; in others, the one side is longer than the other, so that the theca inclines to one side, and is *drooping* or *cernuous*, which must not be confounded with a *pendulous* theca, caused by a curvature of the extremity of the seta. In a cernuous theca, the shorter or under side, instead of being uniformly contracted and smooth like the upper, has sometimes the contraction at one point at its base, and the protuberance thus caused is then called a *struma*. In all but *Andræa*, which has four valves (fig. 161), the theca is entire. Between the seta and the theca is often a fleshy expansion called *apophysis* (fig. 159 a), this always containing, at least when young, a pulpy mass, but no sporules, and being a mere dilatation of the top of the seta. The theca usually opens (fig. 162) horizontally near its apex; the upper part is called an *operculum* or

lid (fig. 162 a): in some genera, however, this lid does not separate from the theca (fig. 161 b), and does not even show any indication of the suture. The operculum is of various shapes, but the terms applied are common to other plants. "The *stoma*, or mouth of the theca, is either naked, as in *Gymnostomum* and *Hedwigia* (fig. 162); or generally furnished with a series of cilia called *teeth* (*dentes*), which may be either in a single series, as in *Splachnum*, *Grimmia*, and *Dicranum* (fig. 165); or in a compound or double series (fig. 166), as in *Hookeria*, *Hypnum*, and *Bryum*. In all mosses which possess a *peristomium*, it arises from the surface of the stoma, or springs from it within the margin and a little below the summit of the theca. In the latter case the teeth are generally more or less connected by a membrane, which not unfrequently rises to a level with the stoma, or even above it. Sometimes all vestiges of the teeth then disappear, thus presenting the aspect of a truly membranaceous peristome, as is seen in *Diphyscium* (fig. 167) and *Leplostomum*; and in such as have a double peristome of regular teeth, the inner one is formed by this membrane, split into a fixed number of attenuated segments. Sometimes, though rarely, the stoma is furnished with a dense horizontal *epiphragma*, not accompanied with teeth (as is the case with the *epiphragma* of *Polytrichum*), an instance of which occurs in *Lyellia*; or, what is still more curious, is supplied with a pencil of fine capillary cilia, as is exemplified in *Dawsonia*."¹ The number of teeth is always some multiple of four. Outside of the teeth, and between the edge of the theca and the operculum, is to be observed in some plants an elastic ring or *annulus* (fig. 165 a), the presence or absence of which, however, does not appear to be of great importance. "Within the theca (fig. 168 and 169), and attached to its sides and base by a cellular pulp intermingled with very slender filaments, is placed a membrane which forms a complete lining. Proceeding from the stoma or mouth downwards, it is continued to the base, when it is reflected upwards, forming a central column, till on a level with the mouth of the theca. This part has been generally denominated a *columella* (fig. 161, c), and is very different from the placenta in cotyledonous plants, to which it has been sometimes compared. A bag is thus formed between the columella, and that part of the same organ which lines the theca, in which the sporulæ are situated. The whole is closed by a very subtle membranous expansion, stretching between the summit of the lining and the columella, which (although in *Gymnostomum* it is often of a stronger texture), by the maturing of the theca, and separation of the operculum, lacerates, and in most instances becomes evanescent. On the open apex of the columella is fixed another membrane, more or less of a conical form, and of a somewhat different texture and colour, which by age often shrinks to the appearance of a mere lid to its orifice. Sometimes it is more rigid (as in *Splachnum*, *Tayloria*, and *Gymnostomum Donianum*), and is then not unfrequently called an *exserted columella*. It also in some cases adheres closely to the summit of the interior of the operculum (as in *Gymnostomum Heimii*, and *Hypnum dendroides*), which it raises or depresses according to the degree of dryness or humidity to which it is exposed. It is this part which we conceive to be the stigma of Palisot de Beauvois, but which we propose to designate by the more appropriate name of *opercular membrane*."² Mr Lindley has with great ingenuity lately suggested, that the calyptra may be understood as a convolute leaf, the operculum another, the peristome one or more whorls of

¹ Arn. and Grev. in *Mem. Wern. Soc.* vol. iv. p. 121.

² *Ibid.* vol. iv. p. 114.

Glossology.
Pl. CXV.

minute flat leaves, and the theca itself to be the excavated distended apex of the stalk, with which we agree; but he, in addition, supposes that the cellular substance of this dilated apex separates in the form of sporules, an hypothesis started by Richard,¹ and agreed in by Brown and Hooker. To this, however, there are, we conceive, many grand objections. As to the supposed anthers, whether the contained powder be imperfect pollen, or, as others say, a second kind of sporules, too little is yet known to render them even of use for the characters of genera. Meese asserts he saw them germinate like sporules; and Dr Roth presumes them to be analogous to the gemmæ, or buds of other plants formed by a superabundance of juices.

Hepaticæ.

6. *Hepaticæ*.—The reproductive organs are here of several kinds, but bear the strongest resemblance to those of the mosses. The theca is, however, destitute of an operculum. In *Jungermannia* (fig. 170) it splits into four longitudinal valves, and is supported by a delicate membranous peduncle or seta (*a*) arising from the frond; the whole, when very young, is moreover protected by a delicate calyptra (*b*); but this does not loosen its attachment to the receptacle or portion of the frond, but splits at the apex to permit the elongation of the seta. This calyptra is placed within another (fig. *c*) either single or double cover, less delicate, and more of the texture of the frond, which may be termed a volva, but is generally, though very improperly, called a calyx; and this, which is of different forms, however insufficient for a generic distinction, is admirably suited for specific characters. When the theca bursts, the sporules are found to be intermixed with elastic spiral filaments or elateres (fig. 170, *d*). But besides the theca, minute spherical cellular bodies have been discovered in many species; and these are supported by short stalks, and have been by some termed anthers. *Monoclea* (fig. 171) bears a very great resemblance to *jungermannia*; the volva is however less distinct, but the calyptra (corolla of some) is considerably elongated (*a*), and tubular. The theca is borne by a seta (*b*); it does not burst into four valves, but splits up on one side (*c*), and presents a central filiform body (*d*), called a columella, about which are the sporules, mixed with elateres (fig. 172). In *Targionia*, the volva arises from the under side of the frond, and of a texture between membranous and coriaceous, marked by a vertical prominent line, by which it separates into two valves: within this are several slender bodies, supposed by some to be anthers; and one spherical, covered by a calyptra, which bursts vertically. Within this, again, is the theca, upon so very short a stalk as not to be, when mature, protruded beyond the volva. The theca appears to burst irregularly, has no columella, and the sporules are mixed with elateres. In *Marchantia* (fig. 173), the volva (here called usually a common receptacle) is peltate (*a*) and on a stalk; it is either flat or conical, and bears on its under surface, not one calyptra, as in the other genera we have noticed, but several, each of which (fig. 174, *a*), bursting at its apex, that is, the point nearest the frond, discloses a theca (*b*), which opens by eight short teeth or valves, united below, and contains sporules and elateres. Other peltate volvas or receptacles, however, occur, having merely oblong bodies imbedded vertically in the disk, and conjectured to be anthers; and besides these there are sometimes little open cups, sessile on the upper surface of the frond, that contain minute gemmæ. *Fimbriaria* differs so very slightly from *Marchantia*, that we may pass it over. In *Anthoceros* (fig. 175) there appears to be no volva; the calyptra (often called a calyx) arises (*a*) from the frond, and is tu-

bular; the theca, supported by a stalk or seta, is linear, Glossology, and splits (*b*) into two valves exhibiting a central columella (*c*), to which the sporules are attached by means of Pl. CXV. very short straight filaments (fig. 176). There are no elateres. The structure of *Sphaerocarpus* is involved in some doubt. We have never had the opportunity of analysing good specimens, but the following seems, from a comparison of the different results of other botanists, to approach nearly to the truth. The whole upper surface of the frond is covered with ellipsoidal volvas (called in this genus *follicles* or *calyces*). These are truncated and perforated at the apex; they are said by some to split into two valves, but this arises from such botanists having only looked at Micheli's figure, in which they are represented cut open by the knife. The volva contains at the bottom a very few linear bodies, the supposed anthers, and one other, the theca, which becomes swollen and spherical, and filled with sporules, destitute of elateres, according to Micheli, though others of less note state that they are present; the calyptra, if present, is closely attached to the theca, and only indicated by a small point at its extremity. *Riccia* (fig. 177) has small excavations in the frond (fig. 178), in which the volva, often scarcely perceptible, rests, containing the theca and calyptra, similar to that of *Sphaerocarpus*: the sporules are unmixed with elateres. There is thus among the *Hepaticæ* such a variety among the organs of reproduction, that no common character is almost to be derived. "The most remarkable point of structure in these plants is the spiral filament, as it is called, lying among the sporules within the theca. This consists of a single fibre, or of two, twisted spirally in opposite directions, so as to cross each other, and contained within a very delicate transparent perishable tube. They have a strong elastic force, and have been supposed to be destined to aid in the dispersion of the sporules; a most inadequate end for so curious and unusual an apparatus."²

7. In the *Algæ*, the sporules, sometimes named granules, Algæ. are variously situated. In some they are contained in distinct capsules or thecæ (fig. 179); in others, in what are termed *tubercles* or *conceptacula* (fig. 180), which are either free or imbedded in the frond, or in a leafy process arising from it; or a multitude of these may be collected close together, into what is then called a common receptacle (fig. 181); and these receptacles in some assume the form of a pod (*siliqua*). The sporules or granules are also often naked, and immersed in the frond (fig. 182); or very rarely external, and surrounded by an open involucre (fig. 183). Sporules with and without a covering (theca or tubercle) frequently exist in the same species, but usually in different individuals. Some genera are tubular, and have the sporular matter scattered or arranged in some determinate manner in their interior (fig. 184); others are gelatinous (fig. 185), either wholly or portions of them, containing naked sporules, which are sometimes mixed with pellucid filaments, and sometimes arranged so as to form moniliform or beaded threads (fig. 186). We, along with Agardh, unite to the *Algæ* the *Characeæ* of authors; and in these there are two kinds of organs (fig. 187). The one (fig. 188) is a *nucule*, *capsule*, or *theca*, sessile, oval, solitary, and unilocular, of two membranes, of which the outer is remarkably thin and transparent, and is terminated by five teeth. The inner one is opaque, and of a thicker texture, and is formed of five narrow valves twisted spirally; the interior is filled with minute granules, but whether these be distinct sporules, or only parts of one large disintegrated sporule, is not yet determined; but each nucleus, on germinating, has been observed to give

¹ Bulliard, *Dict. Elem. Bot.* p. 67.

² Lindl. *Introd. Nat. Syst.* p. 325.

Glossology. rise to only one plant. The second kind of organs has been termed *globules*. Of these the external tunic is very pellucid and indehiscent; the inner seems formed of thin triangular scales, composed of radiating tubes, inclosing a coloured, spherical, pulverulent matter, and the interior of the globule is filled with a multitude of long, simple, crowded filaments, that are diaphanous, and marked with transverse striæ, as in *Oscillatoria* and *Lyngbya*. These filaments appear to be attached to the central portion of the inside of each scale. Smith has arranged *Chara* in monandria monogynia, conceiving the globule to be an anther, and the tubercle a germen, and the five teeth a five-lobed stigma; but the filaments of the supposed anther show the absurdity of such an hypothesis. Walroth asserts that the globules germinate.

Lichens. 8. *Lichens*.—The organs of reproduction (see fig. 189 and 190) are chiefly of one kind, termed *apothecia* or *shields*, or *partial receptacles*. These are formed by nuclei of the medullary substance usually bursting through the cortical portion, which is often raised up, and forms a cup or border round the nucleus; the *sporules* or *gongylæ* are contained in thecae or small membranous tubes, either simple, or composed of several placed end to end: these thecae in some lie free in the nucleus, but in others are previously collected into other cases, termed *asci*. The portion of the nucleus in which the thecae are inserted, by exposure to the air becomes usually harder, and of a somewhat cartilaginous nature, and then often separates from the apothecia. It is called *nucleus proligerus* if the whole of the nucleus becomes so, but *lamina prolifera* (fig. 191) is applied when only the upper stratum contains the thecae. The apothecia are either sessile on the thallus, or connected with it by a narrow neck or stalk called *podetium*. The podetia are in some species cup-shaped at the apex, and, instead of one, bear several apothecia on the margin. This cup is then termed a *scypha*, and the lichens *scyphiferous* (fig. 192). When the apothecia are long and linear, they are by some called *lirellæ*; and even a round apothecium may be formed by the plaiting or convolution of a lirella. In a few genera the *nucleus proligerus* is not protruded beyond the thallus, but is contained within it, merely presenting a small opening or *ostiole* (fig. 193, 194). Independent of the apothecium, there are other parts which appear to have the power of reproduction. These are called *soredia* when they contain a mass of free pulverulent bodies, usually of a whitish colour, that are scattered over various portions of the thallus; and *pulvinuli* when they resemble spongy or amorphous excrescences.

Fungi. 9. *Fungi*.—This tribe borders on the lichens so very closely, as that part of both have been separated into a distinct order called *Hypoxyla*, for which, however, there does not seem to be any necessity. Indeed Agardh remarks of many fungi, that if they had a thallus, they would be lichens. We have already said of them, that the whole plant may be considered as a mass of reproductive matter; and we shall therefore give as short a sketch of them as possible; but, on account of their diversity of structure, we shall be obliged to take them by groups. Brongniart regards the fungi as a class, and divides them into orders; but we are rather inclined to view them as one order, and will take Brongniart's sections, with a slight change of names, as sub-orders.

1. The first of these, and most nearly related to the lichens, are the *Hypoxyla*. Here the sporules are immersed in a hard and ligneous *receptacle* or *peridium*, which opens more or less regularly. Of these there are three tribes. 1. In the *Sphæriaceæ* (fig. 195) there is a terminal pore or cleft, by which the thecae escape in the form of a mucilage (fig. 196): 2. In *Phacidiaceæ* (fig. 197 and 198)

there are several clefts or valves, and the thecae remain fixed: 3. In *Cytisporææ* their orifice is round, but the sporules appear naked, and to have no thecae.

2. *Agaricoideæ*. Here the whole plant is somewhat fleshy or corky, and called a *receptacle*. It is partly covered by a membrane that bears the sporules, which are rarely naked, and scattered on it, but usually inclosed in membranous thecae, and inserted in it. There are three distinct tribes. 1. The *Agaracineæ* (fig. 199) have the membrane distinct, and limited to a particular part of the plant, with the sporules almost always inclosed in thecae, a sub-tribe of which, *Clavariæ*, has straight, club-shaped, simple, or branched receptacles, with the membrane covering nearly the whole; another, the *Agariceæ*, have a *pileus*, the lower surface of which contains the sporuliferous membrane constituting *lamellæ* or gills in *Agaricus*, and *tubes* in *Boletus*; and the *Helvellaceæ* have a pileus, with the membrane on its upper surface. 2. The *Tremellineæ* are soft and gelatinous, and of an irregular shape; they have no thecae, and the sporules are either scattered on the surface of the membrane, or issue from below it. 3. In the *Clethrineæ* (fig. 200) the sporules are mixed with a mucilaginous substance (the sporuliferous membrane), either inclosed in the cells, or on the surface of the plant which arises from a volva.

3. *Lycoperdaceæ*. Here the naked sporules, at least when young, are inclosed in firm, or vesicular, or filamentous thecae, that are again included in the interior of a peridium of a fleshy or membranous nature. 1. *Sclerotineæ* (fig. 201 and 202). This tribe has the peridium indehiscent, and filled with a compact cellular substance or agglutinated thecae, in which are the sporules very indistinct. 2. *Angiogastri* (fig. 203 and 204). Here the peridium, which opens sometimes by means of an operculum, incloses one or more secondary peridia or peridiola (or thecae, but by no means of a membranous nature, as in many other fungi) filled with sporules. 3. *Lycoperdineæ* (fig. 205, 206, 207, 208, 209, 210, 211), where the peridium is usually pedicellated and of a determinate shape, opening regularly, and inclosing the sporules, which soon burst from the thecae, having the appearance of numerous filaments mixed with the sporules. 4. *Fulgineæ* (fig. 212, 213), in which the peridium is sessile, irregular, readily decaying or crumbling into dust. The thecae are filamentous, few in number, and, as in the last, soon losing their sporules, which appear mixed with them.

4. *Mucedines*. In these there is no peridium, while the sporules are naked, and supported by filaments more or less branched and interwoven, in which it is probable they had been at some period contained in all the species. There are five tribes. 1. *Isariæ* (fig. 214 and 215), where the filaments are united one with another in a regular and constant manner, and have the sporules scattered on their surface. 2. *Byssaceæ* (fig. 216, 217, 218), where the filaments are distinct, though often entangled, opaque, without joints, and exhibiting the sporules on their exterior; or jointed, the joints breaking off and forming thecae containing sporules. In some genera of this tribe no sporules have been yet discovered, which has induced some distinguished botanists to suspect several of them to be imperfect states of other plants. 3. *Mucedineæ* (fig. 219, 220, 221). Here the filaments are distinct or loosely entangled, transparent, fugacious, and often articulated; and the sporules are included in the ultimate joints of the filaments, or in small lateral branches, which afterwards separate, or even in the interior of the filaments, without joints, from which they quickly escape, and appear scattered on their surface. 4. *Mucorineæ* (Plate CXVI. fig. 222, 223). The filaments here are transparent, jointed, fugacious, and inflated at their extremity into a mem-

Glossology.
Pl. CXV.

Glossology. branous vesicle, inclosing the sporules. 5. *Phyllerineæ* (224). Here the filaments are simple, without joints, and contain sporules which do not readily escape; they form tufts on the surface of living leaves, and not dead ones, as in most fungi.

5. *Uredaceæ*. In these the thecæ or sporidia are formed of short, continuous, or articulated filaments, which are either free, or supported on a very short and simple stalk, thus scarcely exhibiting the least trace of the filaments observable in the last sub-order. These sporidia spring from under the epidermis or its surface, of either living or dead plants, and are frequently surrounded by a false peridium, formed by the development of the epidermis, or supported on a fleshy or fibrous base, produced by the thickening of the parenchyma of the plant, upon which it is a parasite. There are four tribes. 1. *Stilbosporineæ* (fig. 225), where the sporidia are articulated, and arise from dead plants. 2. *Bactrideæ*. Here the sporidia are simple or unilocular, opaque, fixed or scattered, inclosing numerous extremely slender sporules, which escape towards maturity. This tribe, however, is scarcely either well understood or defined, and perhaps belongs to some other sub-order. 3. *Fusideæ* (fig. 226, 227), in which the sporidia are not jointed, are indehiscent, and spring from the epidermis of dead vegetables. 4. *Uredineæ* (fig. 228), where the sporidia are developed under the surface of the epidermis of living plants.

We have not given the above as a defined arrangement of fungi, but with the view of exhibiting the structure of each of the tribes into which it seems advisable, with some slight alterations, that this extensive order be divided. Much difficulty is often created to the student of these plants, by the diversity of terms to apparently the same thing. Thus, sporidia and thecæ each mean sporule cases; and, on the other hand, sporidia and sporules seem confounded. Hence in one tribe it is said, "though they are called sporidia, it rarely happens that the microscope is able to detect the included sporules; the student therefore must expect the sporidia to appear without sporules."¹ But we ourselves are by no means sure that in any instance do the sporules exist without thecæ. They may be at one time included in filaments, which serve them for thecæ, and must be viewed as filamentous thecæ more or less united to each other end to end; or they may be contained in the cells of the plant, the cellules thus being thecæ; or the thecæ may be so collected as to form a membrane;—but we do not conceive the apparently naked sporules of some species to be any proof of the original absence in them of sporule cases. In this way we think, also, the whole order may be considered in two ways, either as elementary or as compound bodies; the former including such as have no receptacle, and the whole plant constituted of filamentous thecæ; and the latter with a receptacle, in which light the peridium of the *Hypoxyla* and *Lycoperdaceæ* must be regarded. In studying the epiphyllous tribes with the intention of describing them, much attention ought to be paid, although almost entirely hitherto neglected, to the structure of the vegetable upon which the parasite grows; for colours, of great importance in discriminating the larger fungi, may be much influenced by the action of the juices of the plant on which it is formed, and can be here of little use; and even the shape of the peridium, and sorus or cluster of plants, must depend on the texture of the leaf from under the epidermis of which it springs, and through which it bursts. Parasitical fungi may thus, by growing on different plants, assume very different aspects both in colour and form;

and one cannot too much reprobate the manner in which at present many eminent mycologists describe as distinct species every different appearance that presents itself, without previously making themselves masters of the numerous laws by which cryptogamic plants are caused to vary.

Phy-
tography

We thus close what we had to say on Glossology. We have been more particular than we at first intended, in this department of botany; but it was absolutely necessary to give a lengthened view of the formation of the different parts, as well as the names applied respectively to each. For the Linnæan or artificial system such was not requisite; but the great difficulty as well as beauty of the natural system is to view plants analogically,—to consider them, not in their modified, but in their primitive state,—not in the imperfect state in which they appear to our eyes, but in that in which we should see them if fully developed; thus enabling us to exert our minds, and to trace affinities, of which the mere practical botanist can have no conception.

II.—PHYTOGRAPHY.

Under the head of Phytography, the first thing we have to notice is the

Nomenclature.

The necessity of some universally received name to each plant, and of some laws on the subject, has been acknowledged by every one who has made botany a study. Without such, every country would give a peculiar name, and the pursuit would thus become extremely intricate. This alone gives zoology and botany great advantages over mineralogy, in which not only is there no classification of genera and species according to the Linnæan rules, but every species receives a name according to the fancy of the describer, whether or not it has already received one from others.

To obviate such inconveniences, it was at first in use to give to a plant the common name by which it was known in Greece and Italy; but as the knowledge of vegetables extended, this was found to be almost impracticable, both because new plants unknown to the ancients were discovered, and because, from the prodigious number, no person could recollect them all. When, therefore, some resemblance between each other was observed, botanists began to say that one was a *second genus* or kind of such a plant, as *hali alterum genus*, or that it was a *smaller*, or a *yellow flowered* kind, as circumstances might be; and as the number of species augmented, these distinguishing phrases were of necessity made longer, so that, as we find sometimes in Plukenet, a name might consist of twenty words. The inability of the memory to recollect them struck Linnæus forcibly, till at length he proposed that the name of every plant should consist of two words; the one analogous to the name of a family among mankind, the other to the baptismal name of an individual; the former he called the generic, the last the specific. This ingenious method has been termed the *Linnæan nomenclature*, and has been admitted by almost all botanists ever since it was first published in 1753. By it, not only is the memory aided, and enabled to retain the names of many thousands of plants; but, by the same generic name being applied to such as have a certain affinity with each other, that name must suggest to the mind a relationship of which we could not otherwise have an idea. Two inconveniences, no doubt, attend this method; first, it holds out,

¹ Grev. *Flor. Ed.* p. xxv.

Phyto-
graphy.

Phyto-
graphy.

from its simplicity, a temptation to a young botanist to acquire merely the names of plants, without knowing any thing of their character; secondly, from every botanist not viewing the affinity of a plant in the same way, it often happens that the same individual has been placed in different genera, and consequently may have possibly received four or five different generic names. Various plans have been proposed to remove these difficulties; but they have been each, one after another, abandoned.

species.

With regard to what is a species or genus, an order or a class, perhaps no two botanists of the present day are at one; and our limits do not permit us to investigate this point with the attention that some may think it merits. All that nature presents to our eyes consists of *individuals*; but when we assert that one individual is the same, or so similar to another that we think them the same, we give way to our own thoughts, for others may form a different opinion. At the same time many resemblances are so striking as to be obvious to almost all; and when these are confirmed by their seed producing others bearing the same resemblance, we have the idea of what is termed a species. A *species*, therefore, is a collection of all those individuals which have a greater resemblance between themselves than to other plants, and which may by fecundation, one by another, produce fertile individuals, which in their turn reproduce others; and by reversing this procedure, we may infer that all these have arisen at one time from one individual. *Varieties*, again, are departures from the common appearance of the species, and may arise from the seed growing in different climates, subjected to greater or less humidity or heat; or various other causes may be assigned, some of which seem even to produce a permanent effect on the plant, so that after several generations scarcely one seed will reproduce the type of the species. Some botanists most unadvisedly have amused themselves of late years by raising these to the rank of species; but "this eternal splitting of hairs is the bane of natural history, is unworthy of science, and its advocates will one day have to lament that they stood sponsors to such a spurious and equivocal offspring. One tithe of the sagacity they discover in the infinitesimal division of species, directed to other points, would pile up a mountain of knowledge for future use, and immortalize their own names, which, under this present puerile system, will perish with the ephemeral names they are imposing upon undistinguishable things."¹

For long it was considered that a *hybrid*, or cross between two species, could not reproduce a plant, or rather, we ought to say, perfect a seed capable of vegetation; and this test was considered of importance as to the limit of species. But it is now supposed to be of little or no use; the hybrid Pelargoniums, or cape-geraniums, perfecting seed, and multiplying as easily as the parent plants. These plants ought never to be acknowledged by botanical writers. They are contrary to nature, and ought not to be received into any system of nature. They are only fit to amuse the eye and taste of the vulgar and uninitiated. And even if a florist wishes to gain any credit, it were well that he sedulously observed from what the hybrid was obtained; and instead of giving to it an absurd name, as is too often the case, or even a name as if it were a species, he ought to give one that is compounded of those of the two parents. Linnæus, however, laid it down as a maxim, that no hybrid produced perfect seed; and he supported this by many proofs. Those naturalists, therefore, who still adhere to this law, are forced to draw the conclusion, that the supposed hybrid Pelargoniums and

heaths are mere cross variations of varieties of one species; but whichever be the true theory (and we ourselves, if our physiological ideas on the subject be correct, can see no cause why a perfecting hybrid may not be formed between any two plants which have the same anatomical structure of anthers and pistilla), whether these be hybrids or variations, no one has any right to expect space to be occupied by them in a botanical treatise. In so far only as they tend to improve our knowledge of anatomy and physiology, the man of science has to do with them.

Having formed some conception of a species, we may define a *genus* to be a collection of those species which have among themselves a more striking resemblance in their organs, than they have to the organs of others; it therefore bears the same relation towards species as a species does towards individuals. But as it is impossible for all the species of a genus to agree in every organ, so a selection must be made from those that may be considered of more importance than others. But no certain rule can be laid down, farther than that the organs of reproduction being found least liable to variation, are those alone admitted into a generic character. In some genera the stamens, in others the petals, calyx, pistilla, or the fruit, are found to be most convenient for the character; but upon the relative value of these, even in the same genus, different opinions are frequently entertained. A genus may therefore be limited by one in a different way from that adopted by another; and hence we cannot be surprised to find that one botanist places a species in one genus, others in another, according as each thinks it suits best with the collective character. A genus may be also divided into sections, according to some difference of structure in its organs; so that when this difference has been thought of importance, other botanists have raised each of the sections to be a new genus. Thus every day we find that plants, though still retaining their specific names, being married, as it were, into another house, receive new generic appellations. Such is no doubt of great disadvantage to the science, but is unavoidable, from the increasing number of known plants. Nor does it appear that the number of genera is increased in proportion to the discovery of new species. Thus Linnæus, by distributing 7540 species in 1260 genera, ranked on an average only six to each; but, notwithstanding the modern subdivisions in the catalogue of Persoon in 1807, there are about ten to each, and this only contains the phanerogamous vegetables; and in Steudel's *Nomenclator Botanicus*, published in 1821-24, there are of the phanerogamous 3376 genera, and 39,684 species, or about eleven to each; and if we add to these 557 genera, and 10,965 species of cryptogamia, we shall have an average of upwards of thirteen to each genus.

What has been said of genera is applicable to natural families or orders, these containing such genera as have a great resemblance to each other, and are either so closely connected that they cannot be removed, or are separated into groups only for the greater convenience of study. When, however, two or more of these orders bear a closer affinity respectively to each other than to the others to which they are also allied, it has been found useful to term them tribes of one order; but it is then difficult to distinguish between a compound order of this kind and a class. The number of genera in each order is of no importance. There may be hundreds, and there may be but one, solitary but forming a connection between other orders. In general, however, from the consideration that nature forms one continuous chain, we may ex-

¹ Loud. Mag. Nat. Hist. vol. iv. p. 65.

Phy-
to-
graphy.

pect that links remain to be discovered between such isolated genera and the others; and indeed, if the whole of nature were laid open to us, we might infer, notwithstanding all our present labours, that the machinery of orders and genera will be found entirely artificial, and existing only in our own conceptions. Not that it is of no value; for it is of the greatest use, to enable us to bring together in our mind plants resembling each other; and therefore that system must be preferred which tends most to this end.

Classes.

When several natural orders are collected together, having many similarities of structure and appearance, they form what are called *classes*. But very little has hitherto been done as to giving us a knowledge of these. The *Geraniaceæ* (as defined by S. Hilaire), *Rutaceæ* (as collected by Ad. Jussieu), *Tiliaceæ*, and some others, may be adduced as examples. But in botanical systems, where the order must be placed in a linear series, and cannot be described, each at their several points of connection, classes, unless in one or two instances, have been disregarded, and merely the constituent orders themselves introduced.

Language.

As it is essential to natural history that the nomenclature be universal, so it is indispensable that the names be written in some language adopted by all nations. The Greek has been rejected for many reasons, but particularly that the letters are so very different from those now used in the civilized world. To the Latin there are no objections; on the contrary, until within these very few years, it was the general language among scientific and learned men. The names, therefore, as well as the terms of the science of botany, are written in that language; and when such names and terms are translated to give them a more modern appearance, it appears advisable to adhere as much as possible to the Latin words by giving them an English termination. This however is often, but improperly, departed from. In framing names there is a maxim that is deservedly recognized, that they ought to be according to the rules of general grammar. Thus, if the name denotes a property, as thorny-fruited, it is not permitted to derive half of it from the Greek, while the other is Latin; *aculeatocarpa* cannot therefore be retained, but may be changed into *acanthocarpa*.

Priority
of name.

Priority of names must be strictly attended to, or, if names be changed, this must not be done in an arbitrary manner, and without good reasons. But while all agree to this, a difficulty is sometimes started as to what ought to give priority. And here we ought to observe that no manuscript one need be adopted. Farther, no mere name, though published, is of any consequence, unless accompanied by a sufficient character by which the plant may be recognized by others. Names, therefore, in a gardener's catalogue, are of no more importance than manuscript names, although, when made known to botanists by a distribution of specimens, politeness sometimes admits them; but the mere circulation of living plants among horticulturists and florists, not botanists, is not even entitled to this courtesy. Printed names, accompanying collections of dried plants, are always adopted by those who receive them; but it seems doubtful how far such might claim priority, if they were to be first described by others who had not an opportunity of seeing them. It has been argued that plates, without written characters, whether of genera or species, are sufficient to give a priority of name. But this cannot be admitted by the rules of common sense. In those few cases in which the figures of the plant are accompanied with admirably exact and minute dissections, this is sometimes permitted; but it even then

appears questionable, plates not being intended to characterize a species, but as auxiliaries to the character. A character may be sufficient without a plate, but a plate is of no use without a character.

Phy-
to-
graphy.

Generic names, giving the idea of a group, have been by all permitted to stand first, and then the specific name. For the same reason they ought to be substantives; *Mirabilis*, *Gloriosa*, and some others, being adjectives, may therefore be changed. No name ought to be allowed that gives a false idea of the character of the genus; but, on the other hand, such names are always to be preferred as express this character in a precise way; and as it is extremely difficult to express the whole character, the most remarkable points ought to be chosen as contrasted with other allied genera; care being taken that they apply to all the species of the genus. No generic name ought to be derived from the names of places; a few such, however, though faulty, have been admitted. Metaphorical names, derived from ancient history and mythology, have been sometimes bestowed on plants; but great care must then be taken that the allusion is perfect. Linnæus has succeeded very happily in one or two instances, particularly in that of *Andromeda*, his reasons for so naming which we shall give in the author's own words, from the *Flora Laponica*. Comparing her with the plant in question, he says, "virgo hæc lectissima pulcherrimaque collo superbit alto et vividissimo (*pedunculus*), cujus facies roseis suis labellis (*corolla*) vel optimum veneris fucum longe superat; juncea hæc in genua projecta pedibus alligata (*caulis inferior incumbens*), aqua (*vernali*) cincta, rupi (*monticulo*) adfixa, horribus draconibus (*amphibiis*) exposita, terram versus inclinat mœstam faciem (*florem*), innocentissimaque brachia (*ramos*) cælum versus erigit, meliori sede fatoque dignissima, donec gratissimus Perseus (*æstas*) monstris devictis, eam ex aqua eduxit e virgine factam fecundam matrem, quæ tum faciem (*fructum*) erectam extollit. Si Ovidio fabulam de *Andromeda* conscribenti hæc ante oculos posita fuisset planta, vix melius quadrarent attributa, qui more poetico ex humili tumultu produxisset Olympum."¹

The ancients were in the habit of giving plants the names of persons, and this custom has been retained; but care must be taken to select those celebrated in the science, or as having paid great attention to some branch of it. Thus their names will be engraved on our memory so long as the plants are known; and this honour has been therefore considered as one of the greatest that can be conferred on a naturalist. But this is liable to abuse, particularly when princes and others of rank are concerned; plants being often named after persons, who never in any way contributed to the advance of the study. To one person no more than one genus must be dedicated, however great be their services, for if this were to be allowed confusion would soon prevail; thus *Lessertia* and *Delesseria* cannot both remain. As a similarity of sound between two generic names is attended with bad effects, so it ought not to be tolerated, even in the case where we wish to honour a friend. Thus *Belis* cannot be suffered, there being a *Bellis*; nor *Cryphæa*, on account of a previous *Cryphia*; so neither can *Eschscholtzia*, nor *Koniga*, there being already an *Elsholtzia*, and *Koenigia*. When a person has different names, that must be preferred which is best known; but when such is pre-occupied, another may be selected. Great care ought to be taken to preserve rigidly the spelling of names, whatever be the pronunciation. Thus *Czackia* ought not to be written *Tschatschia*, nor *Grahamia*, *Græmia*; nor even is *Brunonia* strictly admissible, although this alteration was made because there

Phy-
tography.

Phy-
tography.

was another Browne, to whom was dedicated the genus *Brownea*. Though by following this rule names be often given not entirely according with the genius of the Latin tongue; yet the end being to perpetuate a particular individual, if the proper orthography were not kept up, a pretext would soon be given for changing the name.

When it is found necessary to divide a genus into two or more, the old name ought to be retained for the group which includes the greater number of species, or to that for which the genus was originally constituted. The last is preferable, but *Erica* and *Ixia* both form exceptions, on account of the great inconvenience of changing the names of so many, when only one would remain unaltered.

As to generic names derived from the vernacular appellations of plants, botanists are not yet agreed. Linnæus, and others after him, wish to refuse all such, although they admit that they may be employed specifically: yet having laid down the rule, the genera *Thea*, *Coffea*, *Gincho*, &c. are almost universally admitted by them; and therefore, in the present day, these and similar ones are generally adopted if their sound be not too barbarous. Schreber, following the maxims of Linnæus, altered nearly all Aublet's names for the Guiana plants, which De Candolle and others now restore. However little desirable it may be to give these names, yet when once given and recognized, it can serve no good purpose, but lead to confusion, to change them.

The older botanists were in the practice of marking allied genera by analogous names, but with a change of termination; thus *Valeriana*, *Valerianella*; *Limonium*, *Limonistastrum*; *Bellis*, *Bellidoides*: all so similar were rejected by Linnæus, who allowed of comparative terms among species alone. As to the termination *oides*, it ought undoubtedly to be laid aside, being an adjective; but the same reason does not apply with equal force to the two other instances; and although we would prefer not to employ them in framing a name, we would hesitate about making a change if already given by others. An anagram, or transposition of the letters of an existing name, is quite contemptible and undignified, and can on no account be permitted. Hence *Galphimia*, made by Cavanilles, and derived from *Malpighia*, is quite unsuitable: in the same way Cassini has amused himself, to the detriment of the science, by splitting *Filago* into as many genera as he could form anagrams of that word, *Filago*, *Gifola*, *Ifloga*, *Logfia*, and *Ofliga*, than which nothing can be more absurd.

Specific
names.

Specific names are less difficult to establish than the generic, because they are meant to apply to an individual, and not collectively; and the chief consideration is not to give one already applied in the genus, or one that has no relation to the plant itself. Almost no change ought therefore to be tolerated, unless when one of these rules be broken through. Thus *Astragalus Monopessulanus*, though found not at Montpellier alone, but throughout all the south of Europe, and even in the western parts of Asia, cannot be altered, because it is actually found at Montpellier; and the name even tends to record the fact of its having been first observed there. But *Potentilla Monspeliaca* is a manifest absurdity, being a native of North America, and merits a change; thus also *Scilla Peruviana* is inadmissible, being a native of Portugal. *Lunaria annua* may also in the same way be changed to *L. biennis*, the plant being not annual, but biennial. There are some botanists, however, who even dislike a change for these reasons; contending, that while in the human race the name George, or Γεωργος, is not applied only to one who is a husbandman, so neither among plants ought we to care what be the name, provided it suffice to distinguish the species; but this is inept, for the above is not

a specific name, nor even that of a variety or variation: but the appellation of an individual.

In general the names derived from countries ought to be given with great circumspection; and from want of due consideration on that point, we have accordingly many absurdities. Thus *Linum Gallicum* is actually found in all the four quarters of the globe. *Ajuga Genevensis*, *Circea Lutetiana*, are not found at Geneva or at Paris alone, but throughout the rest of Europe; still they cannot be now altered. *Agave Americana* is not the only *Agave* found wild in America, for many inhabit also that country. Names taken from stations of plants, as *maritimum* or *palustre*, are frequently good; but such as *campestre*, *alpestre*, or *montanum*, being very indefinite, ought to be avoided as much as possible.

Specific names may be either substantives or adjectives. The former has been usually given when the plant had received a peculiar appellation from old botanists, as *Doria*, *Jacobæa*, *Farfara*; and then the initial letter must be a capital. A substantive is often used in the genitive case when a reference is made to some other genus, as *Pomme-reullia cornucopia*, and then the initial letter is small; or when it is named after some person, as *Ranunculus Gouani*, and then the letter is large. As to adjectives, they must agree in gender with the generic names, and ought to indicate something remarkable in the species. They ought always to commence by a small letter, but of late years botanists have got into a habit of employing a capital when the adjective is derived from the name of a place or person. Adjectives of colour ought to be used sparingly, because the colour of flowers is of very little importance to the species, the same often exhibiting two or more colours. Adjectives of size and qualities are preferable, although these are gradually rendered less applicable by the discovery of new species. Those taken from the agreeable aspect of certain flowers, as *pulcher*, *formosus*, or *amœnus*, are quite absurd, and ought never to be used. Names after botanists may either be substantives in the genitive case, or have an adjective termination. *Lycopodium Hookeri* is an example of the one, *Tulipa Celsiana* of the other.

Specific names may be taken from either Greek or Latin, but they ought to form one word; whence *pes-capræ*, *noli-tangere*, and still worse *noli-me-tangere*, ought never to have been given; and though some of these from courtesy may be permitted to stand, they are not to be imitated.

Varieties are usually indicated by the letters of the Names of Greek alphabet; but when they prove more than usually varieties. important, a name is attached to them similar to a specific name, as *Cratægus Aria longifolia*. Care ought, however, to be taken never to give such, unless the varieties be nearly as permanent as the species itself. Of late, however, by cultivation, so many varieties have been made, and each offering subvarieties or variations, that it were more dignified for botanical writers to omit them altogether, and hand them over for the amusement of florists and horticulturists.

By those who study the natural system, the names of Names of families, or *orders* and *tribes*, must be also attended to. orders. The former have been subjected at different times to different principles. Linnæus and others, seeking general and characteristical features, as in the *Umbelliferae*, *Cruciferae*, *Leguminosæ*, and *Labiatae*; and these, if they could be always obtained with accuracy, are preferable to any others. But even to the few that are admitted, exceptions are found; thus, in some *Umbelliferae* the umbel is so reduced as to appear no longer an umbel; and in some *Leguminosæ* the fruit resembles a nut. Jussieu and Adanson have therefore usually selected some genus, which is the type of the family, and derived the name from it, as *Rosaceæ*

Phy-
tography.

from the genus *Rosa*; and this method is now generally adopted. Care, however, must be taken that the genus be not only one of the best known and most numerous in species, but one which is to give an idea of the general aspect and structure. Thus *Bixineæ* is almost inadmissible, being derived from *Bixa*, a genus that rather forms a connecting link between the above order and the *Tiliaceæ*, and consequently improperly taken as the type. When once the genus is chosen, we must attend to the terminating syllables, for it would not do to adopt simply the plural, as *Rosæ*, without some change. The common way is to form an adjective ending in *ceæ*, or *ineæ*, as *Tiliaceæ*, *Ericineæ*; those in *oideæ*, meaning a family *analogous to*, and not a family *including*, are obviously to be rejected. Sometimes, when a difficulty is experienced in transforming the generic names into an adjective, some old well known name of the principal genus may be taken, as *Thymeæ*, *Salicariæ*, and then the termination may be the mere plural of the substantive.

When a family is divided into several remarkable groups, these also receive names in the same way as the orders themselves. But a difficulty is often experienced in bestowing names so as not to interfere with that of the family, and therefore a rule has of late been laid down, that the names of orders or families be made adjectives by prolonging the generic name one syllable, as *Ranunculus*, *Ranuncula-ceæ*, but that the names of tribes be formed of an adjective without prolongation, as *Ranunculus*, *Ranunculeæ*; and this law is now generally followed.

Synonyms.

If nomenclature be indispensable for communicating our ideas to others, synonyms, or a list of synonyms, are no less necessary for recognizing the name that ought to be preferred to every other, and for reading the works of older writers, or of those who lived before a systematic nomenclature was adopted. By this means we are enabled to have recourse at once to the different authors whom we ought to consult, and from whom we may derive instruction; and without such help we might spend days or weeks in seeking for the information we require, and, after all our labour, would not be able to impart it to others. The number of synonyms quoted must vary much, according to the size of the work. When there is sufficient room, not one ought to be omitted; but if, on the other hand, it be an elementary work within a narrow compass, only the principal synonyms need be brought forward; and under these we of course allude to the fullest descriptions, and best figures, that can be most readily consulted by the readers. A reference to the original describer of the species ought in almost no case to be omitted: thus, Linnæus, Bieberstien, Gunner, and Pallas, have each of them made a *Gentiana ciliata*; and it is important to the reader to know of whom the *G. ciliata* is. In quoting synonyms, very little attention is paid to accuracy; and the consequence is that more confusion is created than if all had been omitted. None indeed ought to be cited, unless the writer has the strongest reason for thinking himself correct, otherwise the reference must be made with doubt (?). De Candolle has recommended, and with great propriety, that, in every one which the author has had it in his power to verify by the inspection of an authentic specimen in an herbarium, the sign (!) be placed after the synonym, indicating that such are most worthy of attention, the others being supposed to be taken from descriptions, which, however good, are not to be always confided in. Old figures, being usually executed by artists not botanists, are of little use except to give a very general idea of the plant; and even among modern figures, when there is a difference, as often happens, between them and the description, greater reliance is to be placed on the latter than on the former.

Phy-
tography.

Botanical style is the art of characterizing and describing plants, so that they may be ascertained by others. Before Linnæus there were no fixed rules, each person adopting what to himself seemed best; but in reforming other points, that distinguished naturalist directed his attention also to this; and although, by following his views, one was restricted to a peculiar form of words, yet the advantages were very readily perceived, inasmuch as his plan put a stop at once to the many vague and insignificant descriptions which were too often indulged in by those of a flowery or poetical genius.

A character in natural history is that peculiar mark by which one being, or one collection of beings, may be distinguished from all others. When this is employed to distinguish a species, it is said to be *specific*; when belonging to a genus, *generic*; to an order, *ordinal*; and so on. The principal merit of characters is to bring together what can be most easily compared, and therefore such as are found in one and not in another are the best.

The characters of classes and orders are very different, according as an artificial or a natural arrangement has been adopted. In the former case they are very simple; in the latter, each being as it were one great genus, they must be still more extended than the character of a genus. Adanson and Linnæus, therefore, thought it impossible to give characters to a natural order; but they erred in seeking one by itself, and not a combination of several. Jussieu made the attempt, and the example or method which he set to others is still called the Jussieuan system, in opposition to the strictly artificial one founded by Linnæus. It is strange that the latter botanist, when he discovered that natural genera could not be defined in few words, did not apply the same train of thought to natural orders. Had he made the attempt, he must have succeeded, and another wreath would have been added to his crown, which has shed immortal honour on that of another. The characters of orders, when complete, must embrace a full description of all the organs of reproduction found in them; but as this is too long for common use, they are usually presented in a much abridged form. But even an abridged character may often be much shortened, and it is then called by Mr Lindley a diagnosis, comprehending only the distinctive characters of the orders, reduced to their briefest form, and without reference to the anomalies or exceptions which are often met with. For a character in full we may refer to *Cruciferae* in De Candolle's *Systema Regni Vegetabilis*, vol. ii. p. 139, which it is unnecessary here to cite. The abridged characters we shall have occasion ourselves to use.

The characters of genera vary also according to whether the artificial or the natural system be adopted. Linnæus, following the former, found the necessity of giving two kinds of character. The one, which he named the *essential*, contained no more than what was needful to distinguish the genus from others in the same order. The other, which he termed the *natural*, contained a short description of all the parts connected with the flower, and was necessary for the complete understanding of the genus; for without it one could not have the slightest idea of its true form, nature, appearance, or relations; and indeed his *Genera Plantarum*, written soon after his return from a visit to Jussieu at Paris, and containing natural characters, seems written in an entirely different spirit from that in which he had executed his *Species*. We do not mean that any improper inference should be drawn from this, but merely mention it as a very striking circumstance. In the natural system there is no occasion for these double characters; most of the lengthened character, as given by Linnæus, being contained in that of the order which in-

Phy-
to-
graphy.

cludes the genus. But, on the other hand, if a genus have a number of peculiar characters, every one must be mentioned; so that here the generic characters, though not so long as the natural ones of Linnæus, must almost always be a little longer than his essential characters. To the generic character ought to be added a short account of the fundamental organs, remarks on its natural affinities when necessary, or any of its peculiarities, and the derivation of the name.

Species.

Specific characters ought to be the same, whatever be the system; but in general, those who adopt the artificial content themselves with making them, as Linnæus prescribed, so very short as to contain only the distinctive marks, and on no account to exceed twelve words. Many of those who follow the natural method introduce as many of the peculiarities of the species as they can, so that it may exhibit a very short description. But, perhaps, without limiting ourselves to any particular number of words, it may always be preferable to make the specific characters, or *phrases* as they are called, as abridged as possible, without being indistinct, and then, when necessary, to add what may be denominated the natural character or description of the species. In this way it is advisable, as was recommended by Linnæus, that in the phrase, all that follows the name, when in Latin, should be in the ablative case; that it ought to be strictly comparative, and the more contradictory terms employed in two species the better; that the characters derived from the different organs should follow each other in a certain order, beginning with those that apply to most species of the genus, and ending with such as may be nearly peculiar to itself. There can therefore be no such phrase when there is but one species of a genus. *Descriptions* may be either abridged or complete. In the latter case they may contain an account of the root, stem, leaves, inflorescence, calyx, corolla, &c. in the order we have followed under Glossology. When in Latin, the nominative case is to be employed; after a substantive comes the epithets in adjectives or participles; but, for brevity, no connecting verbs are allowed, unless in very peculiar cases, where they cannot be dispensed with without creating great ambiguity. M. de St Hilaire, in a late report given in to the French Institute, on a work by M. Moquin on the family of *Chenopodiaceæ*, seems to think that when the characters of the genus have been given with care, specific descriptions are quite unnecessary. "Après avoir indiqué les caractères de cette tribu, M. Moquin décrit en termes techniques les plantes qui la composent. Il trace avec détail les caractères des genres et se borne pour les espèces à de simples phrases. Nous ne pouvons qu'applaudir à cette méthode. Les descriptions spécifiques complètes sont fort utiles, sans doute, dans plusieurs circonstances; mais lorsqu'un genre se compose de plantes régulières,—lorsque, dans des dissertations générales, on a soumis leurs organes à un examen scrupuleux,—nous pensons, avec un de nos savans confrères (M. de Cassini), qu'il est superflu de redire à peu près autant de fois les mêmes choses qu'on a des espèces à faire connaître." To this we subscribe in the case of a monograph, or of a system of plants, because then we have the opportunity of reforming the generic character to our own ideas; but in giving an account of a new or isolated species, we do not see that, for the satisfaction of other writers, a detailed description can be uniformly dispensed with.

With regard to species, the order usually followed is, first the name, then the specific character or phrase, next the

synonyms, then the locality or *habitat*, the duration of the plant, the time of flowering, &c.; after which the description may be given, with the culture and use; and, lastly, any critical observations that may present themselves.

We shall here give the following, as illustrations of the plates, and in some degree of what we have said.

GEN. I.—CALANDRINIA. KUNTH.

Cosmia, Domb. Juss.

Calyx of two persistent, concave, nearly equal sepals. *Petals* 3-5, hypogynous, equal. *Stamens* 4-15, inserted on the base of the calyx or petals; filaments free; anthers bilocular, opening longitudinally. *Ovary* superior or unilocular; ovules many, attached to the bottom of the ovary by linear podosperms. *Style* 1. *Stigma* clavato-capitate, tripartite. *Capsule* oblongo-elliptical, covered by the persistent calyx, unilocular, three-valved, many-seeded. *Seeds* lenticular; testa crustaceous, brittle; tegmen thin and membranaceous; embryo surrounding a farinaceous albumen.—Herbs succulent; leaves very entire, alternate in those with stems; peduncles one-flowred, axillary or opposite to the leaves, without bractæas; in those without a stem bibracteated.

1. *C. pilosiuscula*; stem nearly erect angled, and the leaves linear spatulate, slightly hairy; peduncles axillary, somewhat united to the bractea, constituting a terminal raceme; stamens 10-15.¹

C. pilosiuscula. De Cand. *Prod.* vol. iii. p. 359; Hook. and Arn. in *Botany of Beechey's Voyage*, p. 24.—*Talinum ciliatum*.—Hook. *Exot. Fl.* t. 82 (not Ruiz. and Pav.)—Tutuca. *Feuill. Chil.* vol. iii. t. 41.

Hab. Chili. ☉. Flowers during the whole of summer.

DESCR. *Stem* about a foot or a foot and a half high, erect or decumbent, weak, angular, reddish, and branched below, above greenish, scarcely, and only here and there pilose. *Leaves* scattered, from one and a half to three inches long, linear, frequently inclining to spatulate, acute, more or less patent, the extremities often recurved, the upper surface channelled, the lower subcarinate, especially near the base, the margin distinctly ciliated. *Flowers* at first in terminal leafy corymbs, at length racemose, of a bright purplish red colour, pedicellated. *Pedicels* about half an inch long, thickened upwards, subpilose at their base, which is decurrent, having a large leaf-like bractea, and near that generally another much smaller and appressed one. *Calyx* of two triangular, thickish, green, subpilose, waved leaflets, with their margins more or less incurved, which are erect in the bud, somewhat spread in the flower, and which at length persist, enlarge, and inclose the fruit. *Corolla* of five broadly ovate and slightly notched petals. *Stamens* from ten to fifteen in number. Filaments subulate, purplish, hairy, shorter than the petals. *Anthers* extrorse, ovate, bilocular, pale purplish. *Pollen* yellow. *Pistil* almost entirely surrounded and concealed by the stamens. *Ovary* roundish, green, glabrous. *Style* capitate, with three or four deep purple, velvety, obtuse, spreading rays or stigmas. *Capsule* ovate, inclosed in the calyx, opening with three obtuse valves. *Seeds* numerous, ovato-lenticular, dotted, black, shining, collected into the centre, and fixed to the base by as many distinct filaments, incrassated upwards, as there are seeds. *Embryo* cylindrical, curved, and inclosing the mealy albumen in its centre.

No particular culture is required for this plant. It is quite a hardy annual, and, like others of the same kind, may be sown in spring as soon as there is little probability

Phy-
to-
graphy.

¹ In Latin, *C. pilosiuscula*; caule suberecto angulato, foliisque lineari-spatulatis pilosiusculis, pedicellis axillaribus folio florali subadnatis racemum terminalem constituentibus, staminibus 10-15.

Phy-
tography.

of the germination being injured by the frost. It has been hitherto applied to no use either in medicine or the arts.

The genus belongs to Dodecandria monogynia of Linnaeus, and, like many others referred to it, has no certain number of stamens. This is even more exceptionable than some others, for the stamens are in several species as few as four or five, and, therefore, the artificial system entirely fails. In the natural method its place is obviously among the *Portulacæ*, and next to *Talinum*, with which some botanists unite it; but from that genus it is distinguished by the persistent petals (in *Talinum* deciduous), and ovules attached to the bottom of the ovary by long filiform funiculi (in *Talinum* fixed to a central placenta). As a species its nearest affinity is with *Talinum ciliatum*, Ruiz. and Pav., another species of *Calandrinia*, but there the stamens do not exceed five in number. The *Tal. adscendens*, Hort. Berol., seems identical, and even *Cal. compressa* may be a variety with fewer stamens.

Plate CXVI. *Calandrinia pilosiuscula*. Fig. 1, Plant, natural size. Fig. 2, Petal. Fig. 3, Calyx and stamens. Fig. 4, Stamen magnified. Fig. 5, Calyx and capsule. Fig. 6, Germen, style, stigma, and detached pollen, magnified. Fig. 7, Capsule burst open. Fig. 8, Cluster of seeds on their podosperms. Fig. 9, Seed and podosperm magnified. Fig. 10, Seed cut open longitudinally, exhibiting the embryo and albumen.

GEN. II.—VIOLA. TOURN.

Sepals five, auricled at their base. *Petals* unequal, the lower one spurred. *Stamens* five, approximated; filaments distinct; anthers connate; the two lower ones with processes at their back. *Capsule* one-celled, three-valved, opening elastically.—Herbs for the most part perennial, very rarely annual, some with a very short stem, others caulescent, and even suffruticose; leaves alternate; peduncles solitary, axillary, one-flowered, bibracteolate; flowers cernuous.

Sect. *Leptidium*.

Stigma resembling a proboscis, with a minute foramen at the apex; style flexuose.

1. *V. hederacea*; stem short, stoloniferous; leaves fasciculate, reniform, slightly toothed, on long petioles; stipules subulate; sepals scarcely produced at the base; lower petal, oval, bifid, gibbous at the base beneath.

V. hederacea. La Bill. *Fl. Nov. Holl.* vol. i. p. 66, t. 91; De Cand. *Prod.* vol. i. p. 305; Hook. *Exot. Flor.* t. 225.

Hab. New Holland. 24. Flowers in May in the greenhouse.

DESCR. Glabrous. *Stem*, or point from which the leaves spring, scarcely any, and apparently constituted by the united bases of the petioles throwing out long filiform stolones, which again produce clusters of leaves at various distances, and always at the base of each cluster send forth a rather strong fibrous branching root. *Leaves* fasciculated, from 3-6 in a cluster, an inch broad, when young almost cuneate and their sides rolled inwards, afterwards reniform and plane, or even convex on the upper surface, obscurely nerved, the margin denticulated, placed upon slender grooved petioles from two to four inches long. *Peduncles* or scapes from the axils of the leaves erect, longer than the leaves, with an indistinct groove, and two subulate bracteas near the middle. *Calyx* shorter than the corolla, cut into five spreading, ovato-lanceolate segments, scarcely at all produced at the base. *Flowers* scentless, purple, marked with deeper stains, white at the tips. Two upper petals reflexed; two lateral ones obliquely twisted, gibbous or bulging near the base, and pubescent; lower petal oval, bifid, striated, the base

gibbous only on the under side, convex on the upper, green, with a white margin. *Stamens* five; anthers nearly sessile, large, yellow-brown, appendaged at the extremity. *Ovary* obovate. *Style* one, bent at the base, filiform. *Stigma* white, tapering from the style, acute. *Capsule* oval, three-valved, loculicidal; placenta parietal. *Seeds* numerous, with a raphe conspicuous from without. *Albumen* fleshy, white. *Embryo* in the axis of the albumen, straight, orthotropical, or with the radicle pointing to the base of the seed.

This plant succeeds well in the greenhouse. Its use is unknown.

Although placed in the genus *Viola*, this species differs from the others by the scarcely auricled bases of the sepals, as well as by the absence of a decided spur. *Viola* belongs to Pentandria monogynia, and is the type of the order *Violaceæ*.

Plate CXVII. *Viola hederacea*. Fig. 1, Plant, natural size. Fig. 2, Back view of the calyx. Fig. 3, Lower petal. Fig. 4, One of the upper petals. Fig. 5, One of the side petals. Fig. 6, Side view of the lower petal. Fig. 7, Back view of a stamen. Fig. 8, Front view of the same. Fig. 9, Stipule. Fig. 10, Flower, the petals being removed. Fig. 11, Pistil. Fig. 12, Capsule, natural size. Fig. 13, Capsule burst open, magnified. Fig. 14, Seed, magnified. Fig. 15, Seed cut open to show the embryo and albumen.

GEN. III.—LOASA. ADANS.

Calyx tube adhering with the ovary, the limb persistent, 5-parted, equal. *Petals* 5, alternating with the calycine lobes, shortly unguiculate, concave. *Scales* 5, petaloid, alternate with the petals, 2-3-lobed, converging into a cone, and furnished within at the base with two sterile filaments. *Stamens* numerous, the 10 exterior sterile, the rest arranged in bundles, 10 to 17 together, each androphore opposite a petal. Anthers erect, bilocular. *Style* trifid at the apex. *Capsule* turbinato-oblong, 1-celled, 3-valved at the apex, and crowned with the calyx, the valves bearing the placentas at their margins. *Seeds* oval, very numerous, reticulated.—Herbaceous, branched, sometimes twining, for the most part covered with sharp stinging hairs; leaves alternate or opposite, toothed or lobed; peduncles opposite to the leaves, axillary or terminal, one-flowered; petals yellow, rarely white.

1. *L. nitida*; hispid; leaves opposite, cordate at the base, 5-7-lobed, lobes angled and toothed, upper ones sessile; peduncles axillary; lobes of the calyx oblong, acuminate, entire, equal in length to the petals.

L. nitida. Lam. *Dict.* vol. iii. p. 581; Willd. *Sp. Pl.* vol. ii. p. 1177; Juss. in *Ann. du Mus.* vol. v. p. 25, t. 2, f. 2; Tratt. *Tabul.* i. t. 23; Hook. *Exot. Fl.* t. 83; Bot. Mag. t. 2372; De Cand. *Prod.* vol. iii. p. 341; Pers. *Syn. Pl.* vol. ii. p. 71.

Hab. Chili. ☉.

DESCR. *Stem* straggling, weak, succulent, and fragile, two or three feet high, branched in a dichotomous manner, and, as well as the whole plant, clothed with longish hairs (which appear, when seen under a microscope, to be jointed, and to have short reflexed bristles), and still larger hairs or stings, seated upon a swollen sac or bag of poison, similar to what is seen in the stings of the common nettle. *Leaves* all opposite, somewhat five or seven lobed, with the lobes angular and toothed; the lower ones much the largest, placed on long foot-stalks; the upper ones sessile, smaller, and less distinctly lobed. *Flowers* axillary, generally solitary, pedunculated. *Peduncles* at first erect, after flowering bent down, swelling upwards into the pyriform ovary. *Calyx* cut into five, rarely four, deep segments, lanceolate, acute, green, hispid, at first

Phy-
tography.

Phyto-
graphy.

patent, afterwards reflexed. *Corolla* of five, bright yellow, subunguiculate, concavo-ventricose petals, reddish at the base, waved at the margin, at first spreading, then bent back. *Crown* of five broadly ovate scales, red below, white upwards, where there are two slight depressions, and bidentate, somewhat pubescent at the base, where there are three (one on each side and one in the middle) subtriangular, toothed, red, fleshy appendages, each at its upper margin furnished with a yellowish brown, clavate filament. On the posterior side the margins of these scales are seen to be curved in, and to contain two filamentose bodies, curved and slightly pubescent at the base, about equal in length to the scale, and bearing on one side a purplish filament, which exceeds the scale in height. *Stamens*, about ten in each androphore or bundle; at first bent down at an angle, and concealed within the concave petals of the corolla, at length gradually springing upwards, and lying against the style and stigma, between the scales of the nectary. *Filaments* purplish. *Anthers* yellow, ovate. *Pollen* oblong when dry, spherical when moist, and always marked with a central line. *Ovarium* cohering with the tube of the calyx, above which it rises and forms an hemispherical hairy head. *Capsule*, with the persistent calyx, opening into three valves in the superior extremity. *Receptacles* corresponding with the sutures, rather large, fleshy. *Seeds*, several on each receptacle, longish, oblong, attached on one side, wrinkled, brown. *Albumen* white, between waxy and horny, and inclosing in its centre a cylindrical straight embryo, slightly thickened upwards.

This belongs to Polyadelphia polyandria of Linnæus, although by some erroneously placed in Polyandria monogynia, and forms the type of the natural order *Loaseæ*.

Plate CXVIII. *Loasa nitida*. Fig. 1, *Plant*, natural size. Fig. 2, *A Leaf*. Fig. 3, *A Flower*. Fig. 4, *Calyx*, most of the petals, stamens, and scales, being removed. Fig. 5, *Back view of the scale of the nectary*. Fig. 6, *Front view of the same*. Fig. 7, *One of the filaments from within the scale*. Fig. 8, *Stamen*. Fig. 9, *Pollen*. Fig. 10, *Sting*. Fig. 11, *Hair, with its joints and bristles*. Fig. 12, *Ovarium cut through transversely*. Fig. 13, *Seed*. Fig. 14, *Section of the seed, showing the albumen and embryo*. Fig. 15, *Embryo removed from the seed*.

GEN. IV.—BEGONIA. LINN.

Monœcious. **MALES.** *Perianth* usually of four unequal tepals. *Stamens* eight or more. **FEM.** *Perianth*, the tube adherent with the ovary, the limb divided to the base into 4-9 segments, usually unequal. *Styles* three, each with a two-horned stigma; or nine, dichotomously 3-4 cleft, with simple stigmas. *Capsule* triangular, three-winged, three-celled. *Seeds* very minute and numerous.

1. *B. picta*; stem short, pubescent; leaves cordate, acute, wrinkled, doubly-serrated, spotted, hispid; male flowers of four, the female of 4-5 divisions, the two inner the narrowest; capsule with the wings unequal and pubescent.

B. picta. Smith, *Ex. Bot.* t. 101; Hook. *Ex. Fl.* t. 89; *Bot. Mag.* t. 2962; Lodd. *Bot. Cab.* t. 571.—*B. hirta*. Wallich.

Hab. Nipal. 4. Flowers, in September, in the stoves of our gardens.

DESCR. *Root* perennial, of two small, roundish tubers, together with a few thick, fleshy, simple fibres, mixed with others which are more slender and branched. *Stem* short, slightly branched, thick, succulent, green, more or less tinged with purple, hairy. *Leaves* three or four inches in length, few in number, cordate, more or less inequilateral, with a deep sinus at the base, and two large rounded lobes, more or less acute, sometimes acuminate, the mar-

Phyto-
graphy.

gins unequally and doubly serrated, rugose, waved, hispid above, downy, and prominently veined beneath, green at the margins, and axils of the veins stained with dark purple. *Petioles* long, terete, hairy, with a pair of broadly ovate stipules at the base. *Peduncles* from the axils of the leaves, and longer than them, reddish below, green above, bearing one or several flowers, often in a trichotomous umbel. *Flowers* large, rose-coloured, drooping before and after expansion, especially the female. **MALE FLOWER** of four spreading *tepals*, two large, roundish, cordate, hispid, with short red hairs at the back, two inner ones obovate. *Stamens* numerous, and in reality monodelphous, the filaments often forked, yellow. **FEMALE FLOWERS** of four or five divisions; the outer ones rotundato-ovate, hispid at the back; the inner rather smaller, and obovate. *Ovarium* large, cohering with the tube of the perianth, turbinate, thickly pubescent, with branched or rather lacinated, white, reticulated processes, triquetrous, the angles extended into alæ or wings, of which one is larger than the others. *Styles* 3, yellow. *Stigma* bifid, each segment twisted something like the shell of a snail.

We have given a short generic character to this plant, as *Begonia* is the only genus of the natural order to which it belongs, and the description of the order will be given afterwards. In the Linnæan system it is usually placed in Monœcia polyandria.

Plate CXVIII. *Begonia picta*. Fig. 1*, *Plant*, natural size. Fig. 2*, *Style and stigma*. Fig. 3*, *One of the processes of the ovarium which forms the pubescence*. Fig. 4*, *Ovarium cut transversely*.

GEN. V.—CUSCUTA. LINN.

Calyx 4-5-cleft. *Corolla* urceolate or campanulate, the limb 4-5-cleft, with as many scales (sometimes very minute) inside at the base. *Stamens* 4-5. *Ovarium* bilocular, each cell two-seeded. *Stigmas* two. *Capsule* opening transversely. *Cotyledons* inconspicuous.—Parasitical, climbing, leafless plants with filiform stems.

1. *C. verrucosa*; flowers pedicellate; corolla campanulate, five-toothed, segments reflexed, scales fimbriated; stamens five; stigmas nearly sessile, diverging, elongated, subulate; peduncles and calyx verrucose.

C. verrucosa. Sweet, *Brit. Fl. Gard.* t. 6.—*C. reflexa*, var. *verrucosa*. Hook. *Exot. Fl.* t. 150.

Hab. East India. 4. Flowers in November in cultivation at Edinburgh.

DESCR. *Stem* of great length, filiform, branched, leafless, succulent, climbing from right to left (contrary to the motion of the sun), shining, glabrous, greenish-white, spotted and dashed with purple, adhering parasitically by means of small, fleshy, discoid radicles. From various parts of the stems and branches proceed racemes or compact panicles, formed of a considerable number of large, pure white, waxy, and slightly pellucid fragrant flowers, the smell of which resembles that of the primrose. *Peduncles* and *pedicels* sprinkled with many elevated shining dots or warts, of a deep purple colour. *Bractæas*, two or three on the pedicels, or at the base of the calyx, small ovate. *Calyx* of five fleshy, white or pale rose coloured, ovate, obtuse, appressed, warted segments, persistent. *Corolla* deciduous, campanulate, or very slightly contracted at the mouth, five-toothed, the teeth reflexed; at the base of the corolla, on the inside, alternating with its teeth, are five short fringed scales. *Anthers* five, sessile on the corolla, just within its mouth, and alternating with the segments, oblong, yellow. *Filament* incorporated with the corolla, forming an elevated line between the anthers and the back of each scale. *Ovarium* roundish-ovate, superior, and not at all adherent with the calyx, bilocular; each cell

Phyto-
graphy.

with two ovules, tipped with the two, nearly sessile, subulate, white *stigmata*. *Capsule* the size of a pea, terminated with the style and stigmas, spherical, membranaceous, opening transversely near the base, imperfectly two-celled; the dissepiment membranaceous, free, each cell two-seeded; one or sometimes both seeds in a cell not unfrequently abortive. *Seeds* attached to the base of the cells, erect, roundish, compressed. *Albumen* copious, between fleshy and corneous. *Embryo* filiform, long, spirally rolled up, and immersed in the albumen, as in fig. 8, where only portions of it are visible.

This grows with great luxuriance when plunged in the tan-pit. It is of no use.

This genus has been usually described as having no cotyledons; but, however inconspicuous they be, we are not warranted by analogy to draw such a conclusion: both bractees and a calyx are perceptible, and these we know to be modified leaves. Although, therefore, leaves and cotyledons do not appear perfect, we may infer that they exist in a rudimentary state. It belongs to Pentandria digynia, and Nat. Order, *Convolvulaceæ*. As a species, it coincides perhaps too closely with the *C. reflexa* of Dr Roxburgh, but that species has smaller flowers, and the calyx and peduncle have not been observed to possess the remarkable warts of that before us.

Plate CXIX. *Cuscuta verrucosa*. Fig. 1, *Plant*, natural size. Fig. 2, *Corolla cut open, showing the stamens and scales at the base*, magnified. Fig. 3, *Calyx and pistil*, magnified. Hab. Islands of Banda, a group of the Molucca isles. 5.

DESCR. *Trunk* from twenty-five to thirty feet, much branched, with a greyish brown, tolerably smooth bark, that abounds in a yellow juice. *Leaves* 3-6 inches long sub-bifarious, penninerved, oblong, or nearly elliptical, somewhat obtuse at the base, acuminate at the apex, quite entire, glabrous, dark green, and somewhat shining above, beneath much paler, but neither pulverulent nor pubescent; lateral nerves parallel, simple, prominent. *Petioles* $\frac{1}{2}$ – $\frac{3}{4}$ of an inch in length, plane above. *Flowers* in axillary subumbellate ra-

ces, sometimes forked or compound, males and females on different trees. *Peduncles* and *pedicels* subclavate, glabrous, the latter having a quickly deciduous bracteole at its summit, often appressed to the flower. MALE FLOWERS from three to five, or more, on a peduncle. *Perianth* urceolate, thick and fleshy, of a dingy pale yellowish colour, clothed with a very indistinct reddish pubescence, cut into three, or by luxuriance, and rarely, into four, somewhat erect teeth. *Filaments* of the *stamens* united and incorporated so as to form a thickened, whitish, cylindrical body, about as long as the perianth, of which the top is rounded, and the upper half covered by about eleven longitudinal, linear oblong, two-celled *anthers*, free at their base, opening longitudinally, and emitting a yellow pollen. FEM. FL., similar to the male, except that the pedicel is very frequently solitary on the peduncle. *Perianth* deciduous. *Pistil* solitary, shorter than the perianth, broadly ovate, a little tapering upwards into a short *style*, and bearing a two-lobed persistent *stigma*. *Fruit* a nearly spherical, pendent *drupe*, of the size and nearly of the shape of a small pear; *flesh* of a yellowish colour, almost white within, one-third to one-half an inch in thickness, opening into two nearly equal valves, exhibiting the nut and mace, which soon drop out, and the flesh then withers. *Arillus* thick, somewhat horny or fleshy, lacinated, folded and anastomosing towards the extremity, closely enveloping the nut, of a brilliant scarlet colour. *Nut* broadly oval; *shell* very hard, rugged, dark brown, glossy, about half a line thick, pale and smooth within. *Seed* oval, pale brown, quite smooth (when first deprived of the shell, but soon becoming shrivelled as it is sold in our shops). *Testa* and *tégmen* thin. *Albumen* firm, fleshy, whitish traversed with reddish-brown oleiferous veins. *Embryo* fleshy, yellowish white, imbedded in a cavity at the base of the albumen. *Radicle* short, rounded, pointing to the hilum. *Cotyledons* two, large, foliaceous, plicate.

The use both of the mace and nutmeg are well known, whether in a medicinal or economical point of view; an essential oil is prepared from them by distillation and expression. The flesh contains a bitter principle, which may be much removed by repeated washings, when the fruit is preserved in sugar.

Myristica belongs to Diœcia monadelphia of Linnæus, and to the natural order *Myristicææ*. It was referred by Jussieu to the *Laurinææ*, but differs in many important characters.¹

GEN. VII.—EUPHORBIA. LINN.

Flowers monœcious in the same involucre: the female solitary and central: the males several, surrounding the female. *Involucre* either regular, or more frequently irregular and cleft on one side, campanulato-turbinate, 4-5 cleft; the segments entire, or fimbriated, or multipartite, and erect or inflected; alternating with which are as many (or rarely fewer) exterior appendages, fleshy, glandulose,

¹ We have been indebted for the above descriptions, and the accompanying plates, to the works of Professor Hooker, the most elegant botanical writer and draughtsman of the present day. All the plates which follow, with the exception of Plate CXXXIII., are also copied from those done after drawings made by the same distinguished botanist; they were originally published principally in the *Botanical Magazine*, a work that contains now considerably upwards of 3000 coloured plates, and than which none can better merit the patronage of the public.

Phyto-
graphy.

Phytophy.

Phytophy.

or petaloid, entire or two-horned, or (rarely) many cleft, patent, and reflexed. MALES consisting of several pedicels, each articulated with a filament bearing one anther, usually distinct below, with intervening paleaceous or squamiform bracteas. FEM. *Pistil* long-pedicellate, naked below, or (rarely) with an entire or trifid minute perianth. *Styles* three bifid, rarely united into one trifid at the apex. *Stigmas* six, rarely three and two-lobed. *Ovarium*, three-celled; the cells each with one ovule. *Fruit* capsular, sitting on the elongated pedicel, and nodding by it being deflexed, smooth or warted, glabrous or pilose, trilocular, the cocci bursting elastically into two valves, and deciduous.—Milky plants, herbaceous or shrubby, erect or creeping, of various appearances.

1. *E. hypericifolia*, erect, herbaceous, smooth. Leaves opposite oblique, and half heart-shaped at the base, oblong, somewhat obtuse, serrulate; petioles very short, with stipules at the base; corymbs of flowers dense, axillary, or terminal.

E. hypericifolia. Linn. *Amœn. Acad.* vol. iii. p. 113; Hook. *Exot. Fl.* t. xxxvi.

Hab. West Indies. ☉ or ♀. (Humb.)

Of this and the following we do not give either detailed characters, or a long list of synonyms, but exhibit longer generic characters, that the plates may serve to illustrate some of the natural orders.

Plate CXXI. *Euphorbia hypericifolia*. Fig. 1, *Plant* natural size. Fig. 2, *Involucre* with petaloid appendages. Fig. 3, *Involucre* cut open to show the insertion of the numerous naked monandrous male flowers, and the single naked female flower, all pedicellate. Fig. 4, *Involucre* deprived of the petaloid appendages. Fig. 5, *Involucre* with ripe fruit. Fig. 6, *Stipule*. Fig. 7, *Stamen* and anther burst open. Fig. 8, *Fruit*, with one of the cocci separating from the columella, and bursting to discharge the seed. Fig. 9, *Seed*. Fig. 10, *Seed* cut open longitudinally, showing the fleshy albumen and inverted embryo.

GEN. IX.—ESCHSCHOLTZIA. CHAMISSE.

Calyx ovato-conical, membranaceous, mitriform, very soon falling off entire. *Petals* four, their claws short, inserted on the expanded hollow apex of the peduncle. *Stamens* partly inserted with the petals, and partly attached to their claws, numerous, 6-8 opposite to each petal. Anthers terminal, linear, two-celled, the cells bursting longitudinally. *Ovarium* free, elongated. *Stigmas* sessile, four, two of which are longer than the other two, which are abortive. *Capsule* siliquiform, cylindrical, marked with ten ribs and ten striæ, two-valved. *Placentas* marginal. *Seeds* small, globose, externally reticulated. *Albumen* fleshy. *Embryo* straight, immersed in the albumen near the base of the seed, the radicle pointing to the hilum.—Stem abounding in a yellowish juice; leaves alternate, multifid; peduncles opposite to the leaves, and one-flowered, expanding at their apex into a hollow receptacle.

1. *E. Californica*.

E. Californica. Cham. in *Hor. Phys. Berol.* p. 74, t. 15; Hook. in *Bot. Mag.* t. 2887; Lindl. in *Bot. Reg.* t. 1168; Sweet, *Brit. Fl. Gard.* t. 265. This genus belongs undoubtedly to the *Papaveraceæ* of Jussieu, and *Polyandria tetragynia* of Linnæus. We have already said (p. 60), that the name ought scarcely to be retained. It was named by Chamisso in honour of Dr Eschscholz, an excellent botanist and entomologist, who accompanied him as a fellow naturalist in the voyage round the world under the command of Kotzebue. It is not, perhaps, generally known that this gentleman is a descendant of John Sigismund Elsholz, a Prussian botanist, author of a *Flora Marchica*, and after whom Willdenow named the *Elshol-*

zia cristata. The Russians, into whose service the present Elsholz went, wrote his name Eschscholz by mistake. The genus is now so well established, that the alteration to another generic name might create unnecessary confusion."—Hook.

Fig. 7*, *Section* of the same. Fig. 8*, *Embryo*.

GEN. X.—JANIPHA. KUNTH.

Flowers monœcious. Perianth campanulate, 5-partite. *Estivation* convolute. MALES. *Stamens* ten, distinct, inserted on the fleshy discoid torus, five of them alternate with the others, and shorter. FEM. *Style* short. *Stigmas* three, of several lobes; the lobes, as if united into one mass, marked with sinuose furrows. *Ovarium* seated on the fleshy torus, three-celled, the cells each with one ovule. *Capsule* ovate, somewhat acute at the apex, trilocular, the cocci two-valved.—Trees or milky shrubs; leaves alternate, palmate; flowers racemoso-panicled, axillary or terminal; root of some of the species tubercular and esculent.

1. *J. Manihot*; leaves palmate, 5-7-partite, glabrous, glaucous beneath, the segments lanceolate and very entire; flowers racemose.

J. Manihot. Humb. and Kunth, *Nov. Gen.* vol. ii. p. 108; Hook. in *Bot. Mag.* t. 3071.—*Manihot utilisima*. Pohl, *Pl. Bras. Icon.* vol. i. t. 24.—*Iatropha Manihot*. Linn. *Sp. Pl.* p. 1428.—Physic-nut, bitter cassada, manioc, or tapioca, of English writers.

Hab. Brazil. ♀. Flowers in July and August in our collections.

"Two kinds are especially cultivated in the colonies, the *Sweet Cassada* of Browne's *Jamaica* (p. 350), and Lunan's *Hort. Jam.* (vol. i. p. 163), *Manihot Aipi*, Pohl; whose root is of a white colour, and free from deleterious qualities; and the *Bitter Cassada*, whose root is yellowish, and abounds in a poisonous juice. We shall confine our observations to the latter kind, which is the one here figured and described. They seem not to differ in botanical character.

"When it is considered that the *Manioc* belongs to a tribe of plants, the *Euphorbiaceæ*, which is essentially distinguished by its acrid and poisonous qualities, and that the root of the plant itself abounds in a juice of this peculiar character, it cannot fail to excite astonishment in the minds of those who are not already aware of the fact, that it nevertheless yields an abundant flour, rendered innocent indeed by the art of man, and thus most extensively employed in lieu of bread throughout a very large portion of South America; and that even to our country it is largely imported, and served up at table, under the name of *Tapioca*.

"Such is the poisonous nature of the expressed juice of the *Manioc*, that it has been known to occasion death in a few minutes. By means of it the Indians destroyed many of their Spanish persecutors. M. Fernier, a physician at Surinam, administered a moderate dose to dogs and cats, who died in a space of twenty-five minutes, passed in great torments. Their stomachs, on being opened, exhibited no symptoms of inflammation, nor affection of the viscera, nor was the blood coagulated, whence it appeared, that the poison acted on the nervous system; an idea that was confirmed by thirty-six drops being afterwards administered to a criminal. These had scarcely reached

Phyto-
graphy.

the stomach, when the man writhed and screamed with the agonies under which he suffered, and fell into convulsions, in which he expired in six minutes. Three hours afterwards the body was opened, but no alteration was found, except that the stomach was shrunk to less than half its natural size; so that it would appear that the fatal principle resides in a volatile substance, which may be dissipated by heat; as, indeed, is satisfactorily proved by the mode of preparing the root for food.

"By various processes, by bruising between stones, by a coarse rasp, or by a mill, the root of the *Manioc* is broken into small pieces, then put into a sack, and subjected to a heavy pressure, by which all the juice is expressed. What remains is *Cassada* or *Cassava*, which, if properly dried, is capable of being preserved for a great length of time.

"In French Guiana, according to Aublet, *cassada flour* is made by toasting the grated root over the fire, in which state, if kept from humidity, it will continue good for twenty years.

"Cassava-cake, or cassava-root, is the *meal*, or the grated, expressed, and dried root of the *Manioc*, pounded in a mortar, passed through a coarse sieve, and baked on flat circular iron plates fixed in a stove. The particles of meal are united by the heat, and when thoroughly baked in this manner, form cakes, which are sold at the markets, and universally esteemed as a wholesome kind of bread. The Spaniards, when they first discovered the West Indies, found this in general use among the native Indians, who called it *Cazabbi*, and by whom it was preferred to every other kind of bread, on account of its easy digestion, the facility with which it was cultivated, and its prodigious increase. Again, in Guiana, *Cipipa* is another preparation from this plant, and is the name given to a very fine and white fecula, which, according to Aublet, is derived from the expressed juice of the roots, which is decanted off, and suffered to rest some time, when it deposits an amylaceous substance, which requires repeated washing. I know not whether this is exactly analogous to our *Tapioca*. The juice, says Sloane, evaporated over the fire, gives the *Tapioca* meal. But Lunan tells us, that, from the roots of the *Sweet Cassada*, *Tapioca* is made in Jamaica, in every respect similar to that imported, which is done by grating them, washing them, and infusing them in water, and evaporating the liquor so as to obtain a sediment like starch, which must be well dried in the sun.

"The root of the *Manioc* is also the basis of several kinds of fermented liquors; and an excellent condiment for seasoning meats, called *Cabiou*, or *Capiou*, is prepared from the juice, and said to sharpen the appetite. The leaves beaten and boiled are eaten after the manner of Spinach, and the fresh root is employed in healing ulcers.

"From what has been above stated, it will appear that the expression of the juice from the root deprives the latter of its deleterious properties; and that the application of heat to these juices renders the residue also wholesome and nourishing. And whilst cassava-bread is, as Sloane says, in the most general demand of any provision all over the West Indies, and is employed to victual ships, the use of *Tapioca* is still more extended, and throughout Europe is largely employed for the same purpose as sago and arrow-root." (Hook. in *Bot. Mag.*)

GEN. XII.—CARICA. LINN.

Flowers dioecious. *Calyx* (minute) five-toothed. *MALES.* *Corolla* infundibuliform. *Stamens* ten, the alternate ones shorter. *FEM.* *Corolla* deeply five-parted. *Stigmas* five. *Fruit* like a pepo, many-seeded. *Seeds* covered with a wrinkled membrane.

1. *C. Papaya*; leaves palmate, seven-parted, segments oblong acute sinuate, the intermediate one trifid; fruit oblong, furrowed.

C. Papaya. Linn. *Sp. Pl.* p. 1466; Lindl. in *Bot. Reg.* t. 459; Hook. in *Bot. Mag.* t. 2898 and 2899.—*Papaya vulgaris*, Lam. *Ill.* t. 821.—*Papaya Carica*. Gært. *Fruct.* vol. ii. p. 191, t. 122, f. 2.

Hab. South America. 5.

This, the *Papaw* tree, yields a milky juice; and, as Browne mentions, if water be impregnated with it, it will make all sorts of meat washed in it very tender; but eight or ten minutes steeping will render it so soft that it will drop in pieces from the spit before it is well roasted, or turn to rags in the boiling. If old hogs and poultry be fed upon the leaves and fruit, however tough the meat they afford might otherwise be, it is thus rendered perfectly tender. Even the vapour of the tree serves this purpose; hence many people in the West Indies suspend the joints of meat, fowls, &c. in the upper part of the tree, in order to prepare them sooner for the table.

As to the manner in which botanical works may be got up, whether as Monographs of Orders or Genera, as Floras of particular countries or districts of a country, as a Hortus, as a Genera Plantarum, a Species Plantarum, or as a Systema Vegetabilium, or as Botanical Plates; though each be subjected to a few rules, yet much is left to the taste of the author. We shall therefore pass them over, and proceed to an

Herbarium.

Descriptions and figures, however exact they may be esteemed by their authors, have so often been found imputed by others, that some means must be resorted to, that every one may examine for himself the plant treated of. This in a measure may be attained by having access to gardens; but in all our gardens together, perhaps not more than one fourth of the vegetable productions of the globe are cultivated, and of these many have not been made to bear blossoms or fruit, and are therefore useless; nor can they be certainly seen in all states at the very time when we particularly desire them. In a garden, also, the cultivator is seldom an experienced botanist, and we may therefore expect many errors in nomenclature. The name, therefore, so far from assisting us to trace what an author had in view, may tend to puzzle us still more. In a garden, likewise, plants are made as showy as possible, to please the eye, and often depart very much from the type of the species as taken from its original locality. The necessity, then, was soon perceived of preserving specimens of every thing that is described, so that these may be communicated to other botanists, examined by them, and criticised; and as it was impracticable to retain for any length of time specimens in the fresh state, means were devised to extract the juices; and this being accomplished, no alteration could afterwards take place. Such is the origin of an herbarium, which is a collection more or less considerable of different plants, dried as carefully as possible, at a time when they were in leaf, in flower, and in fruit; while a separate collection of fruits alone, either dried, or, if they are fleshy, preserved in spirits or salt water, is called a granary. The mode of drying plants is very simple.

Paper of an absorbent nature (such as common gray or brown packing paper, or old newspapers) must be procured, about seventeen or eighteen inches long, and twelve broad, and a few strong deal boards of the same size. The specimens may be gathered in a large tin box, or in a basket so covered as to exclude the rays of the sun; and when one cannot soon after proceed to dry them, a little water may be occasionally sprinkled over them to keep them fresh. In order to dry them, take one of the boards and lay a few sheets of paper upon it. The quantity of paper will of course depend on its thickness, and on the nature of the specimens; for when they are full of moisture, more paper is requisite than for more tender or less juicy plants; and when they have thick or knobby stems, or large hard fruits, a still greater quantity must intervene between each layer of plants. Having taken, then, some sheets of paper, spread upon them the plants, so as not to allow the one to overlap the other; and with this precaution several may be laid on the same sheet. It

Phy-
to-
graphy.

Phyto-
graphy.

is quite useless to spread out or separate the leaves or flowers with the hand. If the specimen be at all in a fresh state, its natural appearance is best preserved by allowing it to take the position which chance may direct. Above this layer of plants place some sheets of paper, then another layer of plants, and so on till a packet be formed of a foot, or a foot and a half high. When a considerable number of woody plants is in the packet, a few thin boards may be interspersed, to prevent the more delicate plants sustaining injury; this will also flatten the coarse ones more easily. On the top of the packet another board is to be placed, and on it a large weight or dry stone when such can be procured, so as to press the plants, and make them give out their juices to the paper. The weight need scarcely be less than 50 lbs.; and if the plants have thick or woody stems, even 80 lbs. or 100 lbs. may be applied. In travelling, it is impossible to carry about large stones or weights, in which case the plants may be pressed by means of two or three leather belts passing round the packet, and pulled extremely tight. When plants have been subjected to pressure for twenty-four or forty-eight hours, the weight may be taken off, and the paper will be found to have absorbed a considerable portion of moisture from the plants. It must therefore be now removed, and the specimens laid on dry paper, and subjected to the same process as before. This must be repeated until the plants are dry. It may be less troublesome were the sheets, upon which the plants immediately rest, laid down in a dry situation for a few hours with the plants on them. The moisture will quickly evaporate, and the sheet, without disturbing the plants, may be laid upon a layer of dry paper. The wet paper, when thoroughly dried, can be used as often as one chooses. When the specimens are dry, which may be easily ascertained by their stiffness, or not curling up when in a dry situation, they may be packed up (of small ones, fifty or sixty specimens on a sheet), in very little space; only one sheet of paper is then requisite between each layer of plants. Specimens must be gathered, when possible, in dry weather. They ought to be both in flower and in fruit, the latter being obviously as useful as the former to the scientific botanist; and not less than from twelve or fifteen specimens of each kind ought to be taken, one specimen proving frequently of little use. Small herbaceous plants, not more than sixteen or seventeen inches high, may be pulled up by the root, and dried entire; and some that are even longer, as grasses and ferns, may be doubled two or three times. Of larger plants, such as shrubs and trees, specimens are to be taken at least sixteen or seventeen inches long; and if the leaves on a plant vary much in shape, a corresponding number of specimens may be dried of each kind. Those plants which are of a very fleshy or succulent nature, as tulips, &c. ought to be plunged (all but the flower) for a few seconds into *boiling* water. This deprives them of life; and when the extraneous moisture is allowed to dry off, or wiped away with a towel, they may be dried as other plants. Lichens and fungi may be dried in the common way, although those of the latter tribe seldom make good specimens. Mosses grow frequently in tufts, and are to be a little separated by the hand before they be pressed. The larger or coarse sea-weeds ought to be plunged in boiling water, and treated as succulent plants. The smaller ones, when one is hurried, may first be partially dried in the open air, in a shady situation, and afterwards subjected to a very gentle pressure, till quite dry, when they may be packed up with the other plants; and, when our time permits, they will be restored to their original form by washing them in cold fresh water. They are then to be neatly spread out on pieces of writing paper, to which most of the species will adhere; after this they

are to be pressed, and a little attention must then be paid lest the specimens also adhere to the absorbent paper. Taxonomy.

When a packet so prepared is sent from abroad, it ought to contain at least 100 different kinds, or more than 1000 specimens. It may then be placed in a deal box, which is to be well closed, so as to prevent injury from water; and if the box be previously well rubbed or sprinkled within with oil of turpentine, or any other essential oil, the specimens will arrive safe from the depredations of insects. Small fleshy plants and pulpy fruits may be put in a jar of spirits, and forwarded in that state. In the case of fruits, a piece of wire, with a *number*, should be attached, so as to correspond to the dried specimen of that species.

When plants are either dried by ourselves or received in that state from others, our next care is to form the *herbarium*. For this the specimens are to be either glued down on single sheets of stiff white paper, all of an uniform size, or, as the glue attracts insects and prevents afterwards a perfect analysis of the specimen, others prefer attaching them by means of cross bands. Either of these modes will enable us to keep our herbarium in order; but, without assistance, so much time is spent in the fixing them down, that most botanists now keep the plants loose within sheets of paper of a softer texture. This enables us quickly to dispose of our specimens in the collection; and when turned over carefully, very little damage is afterwards sustained. No more than one species ought to occupy a sheet; but owing to receiving the same plant from different authors and different countries, we must often devote several sheets to one species. Each specimen ought to have a label indicating the locality, the name of the donor, when gathered, or any peculiarities about it; and every sheet ought to have attached to it the name of the plant. All the species of a genus may either be separated from those of another, by being placed within a sheet of strong paper marked on the outside with the name of the genus, or by a thin piece of pasteboard, according to the taste of the possessor.

As to the order in which genera are to be arranged, the alphabetical is the worst, and the Linnæan system next. The best is according to some one of the variations of the natural method, it is of little importance which, provided one adheres to it so much that he can by association go to the order without having constant recourse to a catalogue.

When it is necessary to analyse a dried plant, we may expose the flower or fruit to the steam of boiling water, or those that are of a less delicate nature we may detach, and allow to remain in warm water until the parts we are to examine be so softened that we may easily dissect them under the microscope. Much practice, address, and even knowledge of the structure of plants, is however necessary, so that no appearance exhibited on dissection may fail to make some impression on us. Every thing must be observed and theorised on as we proceed. And we may here remark, that the best instrument for this purpose, at a moderate price, is *Ellis's single and aquatic microscope*, which is furnished by Jones (Holborn, London), with five lenses, two of which are reflectors, for three guineas.

III.—TAXONOMY.

As we have already stated, taxonomy is that branch of botany which has for its object the combination of all our observations on plants, so as to form a system or classification.

When science was in its infancy, and when few plants were observed, they were described or treated without any particular arrangement; or if some method was adopted, History.

it was merely empirical, and of little use to others. Theophrastus, Dioscorides, and Pliny, who respectively treated of vegetables, may therefore now be justly rejected as systematists; and we may pass on to a much more modern date, when the characters began to be derived from the organization of plants; for it was only then that botany became a science. But as the organs of plants were various in number, so also were the systems, some botanists giving a preference to one, others to another; some laying chief dependence on the roots, some on the stems, others on the leaves, and others on the inflorescence. Conrad Gessner, born at Zurich in 1516, was the first who demonstrated that the characters drawn from the flowers and fruit were most to be depended on, as these were the most permanent and unchangeable parts of a plant; he also pointed out that certain groups possessed particular characters in common. His work was published in 1541. It does not appear that he gave any preference to one organ more than to another as the basis of a system. Cæsalpinus, born in 1519, at Arezzo in Tuscany, was a follower of Gessner, and may be said to have been the first who actually invented a system. He set out by distinguishing vegetables into trees and herbs; with the former arranging shrubs, and with the latter suffruticose plants. He next divided each of these, the first into two classes, the last into thirteen, according to the fruit and situation of the embryo (which he termed corculum) in the seed. This system, therefore, being a primary approximation to a natural method, will render him ever memorable.

In 1680 Morison published the second volume of his *Historia Plantarum*. In this work a new system is offered, but some of the eighteen classes contained in the second and third volumes possess no genuine distinctive characters. His sections or secondary divisions are 108 in number, and are taken from the figure and substance of the fruit, the number of seeds, sepals, and petals, the figure of the root, the direction of the stem, the colour of the flower, the place of growth, and one from the medical virtues of some of the plants that compose it.

Ray proposed his method to the world in 1682. It was founded similarly to Morison's, and divided originally into twenty-five classes. But this he afterwards carefully corrected and improved at different times, so that the plan of arrangement which at present bears the name of that author is entirely different from what first appeared. It now was made to consist of thirty-five classes, the distinguishing marks of some of which were derived from the habit or external appearance; of others, from the greater or less degree of perfection of the plants, from their place of growth, the number of seeds, fruits, petals, or sepals to each flower, or from the nature of the fruit or inflorescence. They were as follow:—I. Herbs. 1. Submarinæ or sea-plants, including Zoophytes and Corals. 2. Fungi. 3. Musci, including Hepaticæ and Lichens. 4. Capillares or ferns. 5. Apetalæ or apetalous plants, comprehending, among other anomalies, the genus *Equisetum*. 6. Planipetalæ, or those with semiflosculous compound flowers, corresponding to the Cichoraceæ of Jussieu. 7. Discoideæ, containing such of the Corymbiferæ of Jussieu as have a pappus. 8. Capitata, corresponding principally to the Cynarocephalæ of Jussieu, but more extensive, and including all plants with tubular flowers that are collected into a scaly involucre. 9. Corymbiferæ, similar to those of modern botanists, but limited to the species without a pappus. 10. Gymnomonospermæ, or such as were supposed to have one naked seed; to this belongs *Valeriana* and *Armeria*, and, by some unhappy chance, *Thalictrum*. 11. Umbelliferæ. 12. Stellatæ, corresponding to one of the sections of Rubiaceæ. 13. Asperifoliæ. 14. Verticillatæ, or the Labiatæ of Jussieu, and *Didynamia angiospermia* of Linnæus. 15. Polyspermæ,

or those with many apparently naked seeds, as *Ranunculus*, *Malva*, *Potentilla*, and *Alisma*, a most unnatural assemblage: 16. Pomiferæ, the fruit of which resembled an apple, and among these the gourds and passion-flowers: 17. Bacciferæ, or every herb with a berry, whether a potato or asparagus: 18. Multisiliquæ, such as *Aquilegia* and *Sedum*, that had a fruit of apparently several pods: 19. Ditrpetalæ, containing principally *Tillandsia*, but seemingly not understood by Ray himself: 21. Tetrapetalæ, with either a long or a short pod, not however confined to the Cruciferæ of Jussieu, but comprehending *Veronica*, *Euphorbia*, *Plantago*, &c.: 22. Papilionaceæ or Leguminosæ, including *Fumaria*: 23. Pentapetalæ, as *Dianthus*, *Cistus*, *Hypericum*: 24. Pentapetaloidæ, or those with a monopetalous corolla, so divided as almost to resemble five petals, among which are enumerated *Erythraea*, *Apocynum*, *Oxalis*, &c.; but indeed the 19th, the 23d, and the present classes, are much confused by the author: 25. Bulbosæ, and their allies, including a great part of the monocotyledones, as Liliaceæ, Asphodeleæ, Orchideæ, or Irideæ: 26. Graminifoliæ, comprehending the Grasses, Cyperaceæ, and Juncæ: 27. Anomalæ, or those herbs, as *Nymphaea*, *Piper*, and *Polygala*, that were not reducible to any of these. II. Trees. 28. Arundinaceæ, including the palms: 29. Juliferæ, called also Apetalæ, containing those in which the fruit is separated from the stamiferous flower; under which Ray ranked the Amentaceæ and Coniferæ, the Elm, the Mulberry, &c.: 30. Aggregatæ, or trees with the flower and fruit collected together into one mass, as the Fig: 31. Umbilicatæ, with an inferior, fleshy, or pulpy fruit; a heterogeneous set: 32. Non-umbilicatæ, or those where the flower adhered to the bottom of the fruit; these are again divided into Pruniferæ, Bacciferæ, and Pomiferæ: 33. Vasculiferæ, or trees with a dry fruit: 34. Siliquosæ, or trees or shrubs bearing a legume, follicle, or any of such elongated fruits: 35. Anomalæ, or such as are not referable to any of the above. Most authors only enumerate thirty-three classes, by omitting the 24th and 30th, but which nevertheless form a part of his arrangement. Ray gives, in addition, more lengthened characters of several of these, but it is quite unnecessary here to notice them. His principal division into herbs and trees is extremely faulty, and separates plants otherwise very closely allied. His method, however, being a great approximation to a natural one, deserves much praise, and we believe that it was the opinion of the late Sir J. E. Smith, who was well qualified to judge, that Ray as a botanist was eclipsed by few but Linnæus.

To pass over several of an inferior note, we come now to Tournefort. This distinguished individual was born at Aix in Provence in 1656. He was professor of botany at the Jardin des Plantes of Paris, and was sent in 1700 by Louis XIV. to the Levant. He travelled through Greece, and surveyed the borders of the Black Sea and the islands of the Archipelago, and returned to Paris, where he published an interesting account of his expedition. But before he set out, he had already exposed his new system of arranging plants in his *Institutiones Rei Herbariæ*, illustrated by many plates, and containing a description of 688 genera and 10,146 species; and it is difficult to say whether he deserves most honour for his new classification, or for the attempt to characterize the genera and species.

The method of Tournefort is composed of twenty-two classes, of which the characters are derived, 1st, from the consistence and size of the stem, thus dividing vegetables into herbs or suffruticose plants and shrubs, or trees; in which respect his system is subject to the same fault as that of Ray, notwithstanding Rivinus, an intervening botanist, had demonstrated the absurdity of such a division: 2d, From the presence or absence of the corolla: 3d, From

Taxonomy.

the flowers being simple or solitary, or compound or united into a common involucre: 4th, From the corolla being of one (or gamopetalous) or of several petals: and, 5th, From its regularity or irregularity. His classes are:—

HERBS OR UNDERSHRUBS.

§ 1. Flowers Simple or Solitary.

1. Flowers monopetalous, Campaniform.
2. Flowers monopetalous, Infundibuliform and Rotate.
3. Flowers monopetalous, Anomalous.
4. Flowers monopetalous, Labiate.
5. Flowers polypetalous, Cruciform.
6. Flowers polypetalous, Rosaceous.
7. Flowers polypetalous, Rosaceous Umbellate.
8. Flowers polypetalous, Caryophyllaceous.
9. Flowers Liliaceous.
10. Flowers polypetalous, Papilionaceous.
11. Flowers polypetalous, Anomalous.

§ 2. Flowers Compound.

12. Flowers Flosculose.
13. Flowers Semiflosculose.
14. Flowers Radiate.

§ 3. Herbs without Petals.

15. Flowers Apetalous or Staminiferous.
16. Flowers absent, Seed present.
17. Flowers and Fruit invisible.

TREES AND SHRUBS.

18. Flowers Apetalous.
19. Flowers Apetalous, Amentaceous.
20. Flowers Monopetalous.
21. Flowers Rosaceous.
22. Flowers Papilionaceous.

In the 3d class, the term anomalous means irregular, but not labiate; in the 11th, irregular but not papilionaceous. A liliaceous flower, as the 9th class, he afterwards explains to be a regular corolla of six or three petals, or even a monopetalous one with six divisions, but always having a fruit of three cells. The 16th contains the ferns; the 17th the other cryptogamia, which he says were commonly denied both flower and fruit. Such were the twenty-two classes established by Tournefort. Each of them contains sections, of which there are in all 122; and though at first sight it may appear simple and easy of reference, it still presents considerable difficulties, from many of the characters being merely negative, and others by no means decisive.

Artificial System.

The systems we have already noticed, whether of Cæsalpinus, Morison, Ray, or Tournefort, were all of them more or less attempts at a natural classification; and such being the case, their great error was in selecting any one particular part, and not an assemblage, as the ground of division. This, indeed, is the grand difference between a natural and artificial method. The latter has merely in view the knowledge of the names of plants; and its only use being, therefore, to afford an easy means of discovering the name in books, by as slight an inspection of the plant as possible, every one may have an arrangement of his own, and there can be no fixed rule, for the system is purely artificial. The natural method is not solely for the finding out

the names of plants; its grand object is to exhibit, along with the name, the relation which one plant bears to another, and to class them, as near as we can, in the order they would stand with regard to each other in the grand book of nature. To be correct, it ought to be founded on the immutable laws of nature herself, and not on the will of man. But although these two are grounded so differently, they ought not to be viewed as in opposition to each other. "No person, surely, who has published a natural system, without knowing all the plants in the world, will suppose that he has removed every present obstacle, much less anticipated every future obscurity, so that no insuperable difficulty can occur to the investigator of plants by such a system; neither can any artificial system claim such perfection: but they may combine their powers, and co-operate in instruction. The one may trace an outline, which the other may correct and fill up. The first may propose, and the second elucidate; the former may educate and improve the memory and observation for the use of the latter. When they oppose each other, their several defects and weaknesses appear; by mutual assistance they strengthen themselves."¹

"About the end of the seventeenth century, and the beginning of the eighteenth, the necessity of some botanical system, of arrangement as well as nomenclature, by which the cultivators of this pleasing science might understand each other, became every day more apparent. Nor was there any deficiency of zeal among the leaders and professors of this science. Systems, and branches of systems, sprung up over the whole of this ample field, each aspiring to eminence and distinction above its neighbours. Many of these, like the tares that fell by the way side, soon withered for want of root; others, like the *herba impia* of the old herbalists, strove to overtop and stifle their parents; and all armed themselves plentifully with thorns of offence, as well as defence, by which they hoped finally to prevail over their numerous competitors. This state of scientific warfare did not, in the meanwhile, much promote the actual knowledge of plants, though it prepared the way for a final distribution of the numerous acquisitions which were daily making by the more humble, though not less useful, tribe of collectors and discoverers. The success of the Linnæan artificial system is not altogether, perhaps, to be attributed to its simplicity and facility, nor even to the peculiar attention it commanded by its connection with the striking phenomenon, brought into view at the same time, of the sexes of plants. The insufficiency, or at least the nearly equal merits, of the many other similar schemes that had been proposed, began to be most strongly felt just at the time when the great progress and success of practical botany rendered the necessity of a popular system most imperious. While the cause of system was pending, some of the greatest cultivators of science were obliged to have recourse to alphabetical arrangement. This was the case with Dillenius, the man who alone, at the time when Linnæus visited England, was found by him attentive to, or capable of understanding, the sound principles of generic distinction."²

Linnæus was born in the province of Smaland, in Sweden, on the 23d May, 1707. His father wished him to study divinity, but he himself preferred the open air and the gathering of plants. His parent then thought of making him a shoemaker, and in this might have succeeded, had not Rothmann, the provincial physician at Wexicœ, interfered, and persuaded him to permit his son to study medicine; and had such not happened, Linnæus' genius

Taxono-
my.

might have been for ever suppressed. After experiencing many hardships, and living in great poverty, the young naturalist got into favour with Celsius, the professor of divinity at Upsal; and by his exertions, and those of Rudbeck, succeeded in obtaining permission to make a journey through Lapland at the expense of the academy. On his return he published the *Flora Lapponica*. In a few years his fame increased; and, having travelled into Holland and England, he was appointed professor of botany at Upsal after Rudbeck's death, and from time to time honours were showered upon him. His great merit consists in having constituted the genera on better principles, given proper generic and specific names, introduced a better glossology, described species more accurately and according to certain rules, and invented a new system, founded upon the sexes of plants, unquestionably the best and most simple of all the artificial systems attempted either before or since.

system of
Linnæus.

The basis of the Linnæan distribution of plants rests almost entirely on the male organs or stamens; and where no sexes could be distinguished, the proposer of it termed the plants Cryptogamous, and the class including such, the twenty-fourth of his arrangement, Cryptogamia. Among the first twenty-three classes, or phanerogamous vegetables, some have the flowers hermaphrodite or containing both sexes; others again have them separate, or are dichinous. To the former belong twenty classes, to the latter three. Again, hermaphrodite or bisexual flowers may have the stamens either free from the pistillum or united to it, and hence another division; but as only one class belongs to the last, there are nineteen to the first. These nineteen are further divisible, according as the stamens are free from each other or united together. The former may be equal or unequal in length; and those again which are equal may be either definite or indefinite in number. Upon these considerations Linnæus founded his classification, which we will presently exhibit, not indeed precisely as it was left by Linnæus, but as it is now to be found in most of our modern works. While we admit slight changes upon it, the plan or method is unaltered; and it would be as preposterous to say that what is now adopted is not the system of Linnæus, as it would be to assert that the various sketches of the natural system, whether as given by Browne, by De Candolle, by Richard, by Agardh, by Rudolphi, by Hooker, Don, or Lindley, are not variations of the method of Jussieu. All the natural classifications now in use are assuredly founded on that of Jussieu, and differ from each other in a very slight manner, either in the greater subdivisions of the orders, or in the mode of following each other, upon which no two botanists can possibly be agreed; and, in the same way, the artificial system, whether or not we adopt the changes recommended by Smith, or by Withering, or by Sprengel and others, being decidedly grounded on his principles, is that of Linnæus. It is as follows:—

§ 1. Stamens definite and equal.

- Cl. 1. Monandria, or with one stamen.
2. Diandria, or with two stamens.
3. Triandria, or with three stamens.
4. Tetrandria, or with four stamens.
5. Pentandria, or with five stamens.
6. Hexandria, or with six stamens.
7. Heptandria, or with seven stamens.
8. Octandria, or with eight stamens.
9. Enneandria, or with nine stamens.
10. Decandria, or with ten stamens.

§ 2. Stamens indefinite.

11. Dodecandria; stamens from eleven to nineteen.

VOL. V.

12. Icosandria; stamens twenty and upwards, perigynous, or inserted on the calyx.
13. Polyandria; stamens twenty and upwards, hypogynous, or inserted on the receptacle.

Taxono-
my.

§ 3. Stamens unequal.

14. Didynamia; stamens four, two longer than the others.
15. Tetradynamia; stamens six, four longer than the others.

§ 4. Filaments united.

16. Monadelphia; one bundle of stamens, or androphore.
17. Diadelphia; two bundles of stamens.
18. Polyadelphia; several bundles of stamens.

§ 5. Anthers united.

19. Syngenesia; stamens five, united by their anthers, flowers collected into a common involucre.

§ 6. Stamens united to the pistil.

20. Gynandria.

§ 7. Flowers unisexual.

21. Monœcia; stamens and pistils on the same individual.
22. Diœcia; stamens and pistils on different individuals.
23. Polygamia; hermaphrodite and unisexual flowers, either on the same or different individuals.

§ 8. Flowers invisible.

24. Cryptogamia; neither stamens nor pistils.

Although we have prefixed sections to the above, that the method may be understood more readily, yet we must remark that such a plan is liable to errors. Thus some of the fifth class have the anthers united, as in the nineteenth; and the tenth has frequently an inequality in the length of the stamens; but these are not the faults of the system, some of which will be traced out in the sequel.

In the first thirteen classes, the characters of the orders or subdivisions of the classes are derived from the number of the styles or female organs, the names Monogynia, Digynia, Trigynia, &c. indicating respectively one, two, three, &c. styles.

In the fourteenth class, or Didynamia, Linnæus took his ordinal characters from the structure of the fruit. When this is formed of four akenia situated at the bottom of the calyx, so as to resemble naked seeds, he called the order Gymnospermia; and when the fruit was a capsule containing several seeds, he termed the group Angiospermia. Tetradynamia presents also two orders, the one with a silicule, the other with a siliqua; and hence they were called Siliculosæ and Siliquosæ. A third order has been added, by Sprengel, for such as have an indehiscent fruit, and De Candolle has proposed to subdivide the class according to the relative position of the cotyledons and radicle. The sixteenth, seventeenth, and eighteenth classes being according to the union of the filaments, the number of stamens is made to serve as a character for the orders.

In Syngenesia, where the anthers are united, and there are almost constantly five stamens, other means were resorted to. Some florets were observed to be bisexual, others with stamens or pistils only. In reference, therefore, to the twenty-third class, Linnæus gave to each of the orders the name Polygamia, with another epithet to mark their respective peculiarities. The first he terms Polygamia æqualis, all the florets being equally fertile and bisexual; the second Polygamia superflua, where the florets of the disc are bisexual, but those of the circumference or

Taxonomy.

ray female, both producing perfect seed: the third Polygamia frustranea, having the florets of the disc bisexual and fertile, but those of the ray sterile, from either the total absence of a pistil, or the imperfection of the stigmata. In the second order the florets of the ray were only superfluous, here they are totally useless. The fourth, or Polygamia necessaria, has the florets of the disc bisexual, but sterile on account of the imperfection of the stigmas: those of the ray, however, containing only pistilla, are fertilized by the pollen of the former. They are thus necessary for the continuation of the species, and hence the name. The fifth, Polygamia segregata, has all the florets bisexual, but each of them contained an involucre peculiar to itself; the whole, as in the other orders, being collected within a common involucre. To these Linnæus added a sixth, Polygamia monogamia, wherein the flowers were not collected in a common involucre; but this has now been transferred to Pentandria monogynia.

In Gynandria the orders are taken from the number of the stamens. Monœcia and Diœcia, including plants that are monandrous, diandrous, monodelphous, or gynandrous, have the names of the orders, as Monandria, Decandria, Gynandria, taken from some of the preceding classes. The twenty-third class, or Polygamia, containing plants with bisexual and unisexual flowers mixed either on the same or distinct individuals, has in consequence been divided into three orders: Monœcia, in which the flowers are bisexual and unisexual on the same individual; Diœcia, when one bears the bisexual and another the unisexual blossoms of both kinds; and Triœcia, where one has the bisexual, another the male, and a third the female flowers.

Cryptogamia was originally divided by Linnæus into four orders, Ferns, Mosses, Algæ, and Fungi; but so little was then known about the structure and limits of these, that it is now generally agreed to adopt nearly the same divisions as are employed in the natural method.

Service rendered by Linnæus.

"Linnæus¹ had no sooner published and explained his method of arranging plants, according to that which is generally termed the Sexual System, than it excited considerable attention. His elegant and instructive *Flora Lapponica* could not be perused by the philosopher or the physician, without leading its readers occasionally aside, from the immediate objects of their inquiry, into the paths of botanical speculation, and awakening in many a curiosity, hitherto dormant, on such subjects. But the scope of that limited Flora is by no means sufficient to show either the necessity or the advantages of any mode of arrangement. Linnæus may be said to have grasped the botanical sceptre, when, in the year 1753, he published the first edition of his *Species Plantarum*; and the commencement of his reign must be dated from that period. The application of his system to universal practice, in this compendious distribution of all the known vegetables of the globe; his didactic precision; his concise, clear, and certain style of discrimination; his vast erudition displayed in synonyms; and, perhaps as much as any thing else, the fortunate invention of trivial or specific names, by which his nomenclature became as evidently commodious, and indeed necessarily popular, as any part of his performance; all these causes co-operated to establish his authority. An immediate impulse was given to practical botany. The vegetable productions of various countries

and districts were marshalled in due array, so as to be accessible and useful. A common language was established throughout the world of science; a common stock of knowledge and experience began to accumulate, which has ever since been increasing, and can now never be lost. Of these partial Floras to which we allude, those of Lapland and Sweden, the productions of Linnæus himself, were the models of most of the rest, and have never, on the whole, been excelled.

"Hence arose the Linnæan school of botany, which, Linnæan though founded in Sweden, extended itself through Hol- school land, Germany, and more or less perfectly in other parts of Europe, though not without impediments of which we are hereafter to speak. In Britain it was firmly established, by the influence of some of the most able pupils of Linnæus, and strengthened at length by the acquisition of his literary remains. But these are adventitious supports. The strength of philosophical, like political, authority, is in public opinion, and the cement of its power is public good.

"As we proceed to trace the practical influence of the Linnæan system, or rather of the facility which it afforded in botanical studies, it will be useful at the same time to observe the effects of adventitious circumstances, which render botany almost a different sort of study in different parts of the habitable globe.

"In those northern ungenial climates, where the intellect of man indeed has flourished in its highest perfection, but where the productions of nature are comparatively sparingly bestowed, her laws have been most investigated and best understood. The appetite of her pupils was whetted by their danger of starvation, and the scantiness of her supplies trained them in habits of economy, and of the most acute observation. The more obvious natural productions of such climates are soon understood and exhausted. But this very cause led Linnæus to so minute a scrutiny of Swedish insects, as had never been undertaken before in any country; in consequence of which a new world, as it were, opened to his contemplation; and the great Reaumur declared that Sweden was richer in this department than all the rest of the globe. Such indeed was its appearance, because it had been more carefully examined. When the ardour and acuteness of the pupils of the Linnæan school first sought matter of employment for their talents, some few had the means of visiting distant and scarcely-explored countries. But this could not be the lot of many. The greater part were confined to their native soil; and it is remarkable that those who are longest so confined have displayed in the sequel the greatest abilities, and have rendered the greatest services to science, independently of the accidents which made the labours of others imperfect or abortive. Such men as Ehrhart and Swartz were not to be satisfied with the general productions of the fields or gardens to which they had access. They had no resource but in the recondite mysteries of cryptogamic botany in the first instance. To these they directed their microscopic eyes and more discriminating minds with the happiest success. When they had derived from hence an ample harvest, Ehrhart, limited in circumstances and opportunities, hindered morcover perhaps, in some degree, by a singularity and independence of character, not always favourable to worldly prosperity, opened to himself a new path. The

Taxonomy.

Botany of the North

Ehrhart.

¹ This historical sketch, almost to the commencement of the exposition of the Jussieuan or natural method, is extracted from the article BOTANY in the Supplement to the fourth, fifth, and sixth editions of this Encyclopædia, which was written expressly for that work, in 1816, by the late Sir James Edward Smith. During these last fifteen years the grave has claimed for its own not only Sir James himself, but most of the distinguished individuals whom he here notices as being then alive. As it was, however, desirable to retain this sketch entire, the author of the present article has refrained from making those alterations which the lapse of time might otherwise have rendered necessary.

Taxonomy.

Taxonomy.

native trees of the north, and especially the hardy shrubs and arborescent plants of the gardens, had not, as he judiciously discovered, received that correct attention, even from his master Linnæus, which was requisite to make them clearly understood. Difficulties attending the study of these plants, the various seasons in which they require to be repeatedly scrutinized, and the obscurity or minuteness of the parts on which their differences depend, were by no means calculated to deter this laborious and accurate inquirer. He submitted the supposed varieties of the shrubbery, the kitchen garden, and even of the parterre, to the same rigorous examination, and, for the most part, with the happiest success. His discoveries have not received the notice they deserve, for his communications were deformed with asperity and pedantry; and he did not always keep in mind the concise and sober principles of definition, which his preceptor had both taught and practised, and to which he owed so large a share of his well-merited fame. Ehrhart died prematurely, but his name ought to be cherished among those whose talents have advanced science, and who loved nature, for her own sake, with the most perfect disinterestedness.

Swartz.

"The fate of Swartz has been far more propitious to himself and to the literary world. Having thrown more light upon the cryptogamic productions of Sweden and Lapland than they had previously received, and which has only been exceeded by the more recent discoveries of the unrivalled Wahlenberg, he undertook a botanical investigation of the West Indies. Carrying with him, to this promising field of inquiry, so great a store of zeal and practical experience, his harvest was such as might well have been anticipated. Whole tribes of vegetables, which the half-learned or half-experienced botanist, or the superficial gatherer of simples or flowers, had totally overlooked, now first became known to mankind. Tropical climates were now found to be as rich as the chill forests and dells of the north, in the various beautiful tribes of mosses; and the blue mountains of Jamaica rivalled its most fertile groves and savannahs in the beauty, variety, and singularity of their vegetable stores.

Thunberg.

"Nor must we pass over unnoticed the discoveries of another illustrious disciple of Linnæus, the celebrated Thunberg, who has now¹ for many years filled the professional chair of his master, with credit to himself, and advantage to every branch of natural science. The rare opportunity of examining the plants of Japan, and of studying at leisure the numerous and beautiful productions of the Cape of Good Hope, as well as of some parts of India, have thrown in the way of Professor Thunberg a greater number of genera, if not species of plants, than has fallen to the lot of most learned botanists; except only those who have gone round the world, or beheld the novel scenes of New Holland. These treasures he has contemplated and illustrated with great advantage, so far as he has confined himself to practical botany. We lament that he ever stepped aside to attempt any reformation of an artificial system. It is painful to complain of the well-meant though mistaken endeavours of so amiable and candid a veteran in our favourite science; but what we conceive to be the interests of that science must form our apology. We cannot but be convinced, and the experience of others is on our side, that discarding those principles of the Linnæan system which are derived from the *situation* of the several organs of impregnation, and making *number* paramount, has the most pernicious and inconvenient effect in most respects, without being advan-

tageous in any. This measure neither renders the system more easy nor more natural, but for the most part the reverse of both. We have elsewhere observed (*Introduction to Botany*, 3d ed. p. 358), that the amentaceous plants are of all others most uncertain in the number of their stamens, of which Linnæus could not but be aware. 'Even the species of the same genus, as well as individuals of each species, differ among themselves. How unwise and unscientific then is it, to take as a primary mark of discrimination, what nature has evidently made of less consequence here than in any other case!' When such plants are, in the first place, set apart and distinguished by their monœcious or diœcious structure, which is liable to so little objection or difficulty, their uncertainty with respect to the secondary character is of little moment; their genera being few, and the orders of each class widely constructed as to number of stamens. Linnæus, doubtless, would have been glad to have preserved, if possible, the uniformity and simplicity of his plan; but if he found it impracticable, who shall correct him? Such an attempt is too like the entomological scheme of the otherwise ingenious and able Fabricius. The great preceptor having arranged the larger tribes of animals by the organs with which they take their various food, and which are therefore accommodated to their several wants, and indicative of even their mental as well as constitutional characters, Fabricius his pupil would necessarily extend this system to insects. But nothing can be more misapplied. Feeding is not the business of perfect insects. Many of them never eat at all, the business of their existence through the whole of their perfect state being the propagation of their species. Hence the organs of their mouth lead to no natural distinctions, and the characters deduced therefrom prove, moreover, so difficult, that it is notorious they could not generally be applied to practice by Fabricius himself, he having, in the common course of his studies, been chiefly regulated by the external appearance of the insects he described. This external appearance, depending on the form and texture of their wings, and the shape of their own peculiar organs, the *antennæ*, affords in fact the easiest, as well as the most natural, clue to their arrangement and discrimination.

"As we presume to criticise the systematic errors of great practical observers, it cannot but occur to our recollection how very few persons have excelled in both these departments. Ray, Linnæus, and perhaps Tournefort, may be allowed this distinction. We can scarcely add a fourth name to this brief catalogue. The most excellent practical botanists of the Linnæan school have been such as hardly bestowed a thought on the framing of systems. Such was the distinguished Solander, who rivalled his preceptor in acuteness of discrimination, and even in precision and elegance of definition. Such is another eminent man, more extensively conversant with plants, more accurate in distinguishing, and more ready in recollecting them, than almost any other person with whom we have associated. Yet we have heard this great botanist declare, that however he might confide in his own judgment with regard to a species, or a genus of plants, he pretended to form no opinion of classes and orders. Men of so much experience know too much, to be satisfied with their acquirements, or to draw extensive conclusions from what they think insufficient premises. Others, with a quarter of their knowledge, find no difficulty in building systems, and proceed with great alacrity, till they find themselves encumbered with their own rubbish; happy

¹ Thunberg died at Upsal, on the 8th August 1828, in the 85th year of his age, having filled the botanical chair during half a century.

Taxonomy.

if their doubts and uncertainties will afford them a tolerable screen or shelter! But we here anticipate remarks which will come with more propriety hereafter. We return from the consideration of the labours of particular botanists, to that of the diversities of nature and circumstance.

"While it is remarked that, in the cold regions of the north, the skill of the deep and learned botanist is chiefly exercised on the minute and intricate cryptogamic tribes, we are not to infer that nature is not everywhere rich in beauty and variety. Mosses and lichens afford inexhaustible amusement and admiration to the curious inquirer, nor are more gorgeous productions entirely wanting. Even Lapland boasts her *Pedicularis Sceptrum*, never seen alive out of her limits; and Siberia offers her own beautiful crimson *Cypripedium*, to console for a moment the miserable banished victims of imperial caprice. Kotzebue, though ignorant of botany, did not pass this lovely plant unnoticed, even in the height of his distress. The authoress of the pleasing little novel called *Elizabeth*, has represented in a just light the botanic scenery of that otherwise inhospitable country; yet it must be allowed that its rarities are not numerous, except perhaps in those microscopic tribes already mentioned.

New Holland.

"Let us in imagination traverse the globe, to a country where the very reverse is the case. From the representations or accounts that have been given of New Holland, it seems no very beautiful or picturesque country, such as is likely to form or to inspire a poet. Indeed the dregs of the community which we have poured out upon its shores, must probably subside, and purge themselves, before anything like a poet, or a disinterested lover of nature, can arise from so foul a source. There seems, however, to be no transition of seasons, in the climate itself, to excite hope, or to expand the heart and fancy; like a Siberian or Alpine spring, bursting at once from the icy fetters of a sublime though awful winter. Yet in New Holland all is new and wonderful to the botanist.¹ The most common plants there are unlike every thing known before, and those which at first sight look like old acquaintances, are found, on a near approach, to be strangers, speaking a different language from what he has been used to, and not to be trusted without a minute inquiry at every step.

Cape of Good Hope.

"The botany of the Cape of Good Hope, so well illustrated by Thunberg, and with the treasures of which he scattered a charm around the couch of the dying Linnæus, most resembles that of New Holland. At least these countries agree in the hard, rigid, dwarfish character of their plants. But the Cape has the advantage in general beauty of flowers, as well as in a transition of seasons. After the dry time of the year, when every thing but the *Aloe* and *Mesembryanthemum* tribes are burnt up, and during which innumerable bulbs are scattered, by the winds and driving sands, over the face of the country, the succeeding showers raise up a new and most beautiful progeny from those bulbs. The families of *Ixia*, *Gladiolus*, *Iris*, *Antholyza*, *Oxalis*, and many others, then appear in all their splendour. Some of them, the least gaudy, scent the evening

air with an unrivalled perfume; whilst others dazzle the beholder with the most vivid scarlet or crimson hues, as they welcome the morning sun.

"The lovely florae of the Alps and the Tropics contend, perhaps most powerfully, for the admiration of a botanist of taste, who is a genuine lover of nature, without which feeling, in some degree of perfection, even botany can but feebly charm. Of one of these the writer can speak from experience, of the other only by report; but he has had frequent opportunities of remarking, that the greatest enthusiasts in the science have been Alpine botanists. The expressions of Haller and Scopoli on this subject go to the heart. The air, the climate, the charms of animal existence in its highest perfection, are associated with our delight in the beauty and profusion of nature. In hot climates, the insupportable languor, the difficulty of bodily exertion, the usual ill health, and the effects of unwholesome instead of salutary fatigue, are described as sufficient to counterbalance even the pleasure which arises from the boundless variety, and infinite beauty, of the creation around. The flowery trees of a tropical forest raise themselves far above the human grasp. They must be felled before we can gather their blossoms. The insidious and mortal reptile twines among their boughs, and the venomous insect stings beneath their shade. We who enjoy the productions of these climates in peace and safety in our gardens, may well acknowledge our obligations to the labour and zeal of those who, by arduous journeys and painful researches, supply us with the riches of every country in succession. We do not indeed enjoy them in perfection, but we can study and investigate at leisure their various beauties and distinctions. We can compare them with our books, and profit by the acuteness of former observers. We can perpetuate, by the help of the pencil or the pen, whatever is novel or curious. We can preserve the plants and flowers themselves for subsequent examination, and return to them again and again in our closet, when winter has fixed his seal on all the instruction and pleasure afforded by the vegetable creation abroad. Yet let not the sedentary botanist exult in his riches, or rejoice too heedlessly in the abundance of his resources. A plant gathered in its native soil, and ascertained by methodical examination, is more impressed on the memory, as well as more dear to the imagination, than many that are acquired with ease, and named by tradition or report. The labours of its acquisition and determination enhance its value, and the accompaniments of delightful scenery, or pleasing society, are recollected, when difficulties and toils are forgotten.

"The western continent is, with respect to botany, almost a world in itself. There exists, indeed, a general affinity between the plants of North America and those of Europe, and many species of the arctic regions are the same in both; but there are few common to the more temperate climates of each. A considerable number, communicated by Kalm to Linnæus, which the latter considered as identified with certain well-known plants of our quarter of the world, prove, on more accurate examination, to be corresponding but distinct species. Instances occur in

¹ "These rare productions," speaking of palms and arborescent ferns, "of the vegetable kingdom, are, in all other countries, strictly tropical; and these 'weeds of glorious feature' have no business beyond the latitude of $23\frac{1}{2}^{\circ}$ from the equator, and yet here they are in $34\frac{1}{2}^{\circ}$. But this is New Holland, where it is summer with us when it is winter in Europe, and *vice versa*; where the barometer rises before bad weather, and falls before good; where the north is the hot wind, and the south the cold; where the humblest house is fitted up with cedar (*Cedrela Toona*, according to Mr Brown); where the fields are fenced with mahogany (*Eucalyptus robusta*), and myrtle trees (*Myrtaceæ*) are burnt for firewood; where the swans are black and the eagles white; where the kangaroo, an animal between the squirrel and the deer, has five claws on its fore-paws, and three talons on its hind-legs, like a bird, and yet hops on its tail; where the mole (*Ornithorhynchus paradoxus*) lays eggs, and has a duck's bill; where there is a bird (*Meliphaga*) with a broom in its mouth instead of a tongue; where there is a fish, one half belonging to the genus *Raja*, and the other to that of *Squalus*; where the pears are made of wood (*Xylomelum pyriforme*), with the stalk at the broader end; and where the cherry (*Exocarpius cypressiformis*) grows with the stone on the outside." (Field's *New South Wales*, p. 461.)

Taxonomy.

the genera of *Carpinus*, *Corylus*, *Quercus*, as well as in the *Orchis* tribe, and others. These points of resemblance are found mostly among the vegetable productions of the eastern regions of North America. Mexico, and what little we know of the intermediate space, abound with different and peculiar productions. So, in South America, Peru, Guiana, Brazil, &c. have all their appropriate plants, of which we know as yet enough to excite our curiosity, rather than to satisfy it. Whatever has hitherto been given to the world respecting American botany, has had one considerable advantage. Each *Flora* has been founded on the knowledge and experience of some one or more persons, long resident, and in a manner naturalized, in the countries illustrated. Those regions commonly comprehended under the name of North America, have afforded materials for the *Flora Boreali-Americana* of Michaux, and the more complete and correct *Flora Americae Septentrionalis* of Pursh. Michaux, Wangenheim, and Marshall, have particularly illustrated the trees of those countries. But all these works have been enriched by the communications and assistance of men who had much more extensive and repeated opportunities of observation than their authors, except Mr Marshall, could have. Such are the venerable John Bartram, the Reverend Dr Muhlenberg, Messrs Clayton, Walter, Lyon, &c. The Mexican flora has received, for a long course of years, the attention of the able and learned Mutis, who long corresponded with Linnæus, and whose countrymen have prepared the sumptuous *Flora Peruviana*; each of the authors of which has repeatedly traversed, at various seasons, the rich and interesting regions, whose botanical treasures make so splendid and novel an appearance in those volumes. Of those treasures we have still more to learn from the unrivalled Humboldt.¹ The French botanist Aublet, after having gained considerable experience in the Mauritius, resided for many years in Cayenne and Guiana,

for the purpose of studying the plants of those countries, of which his work, in four quarto volumes, gives so ample a history and representation.

"All the writers just named have been practical botanists. They have generally excelled in specific discrimination, nor have they neglected the study of generic distinctions. Any thing further they have scarcely attempted. It is remarkable that they have all followed, not only the Linnæan principles of definition and nomenclature, but the Linnæan artificial system of classification. This same system was chosen by the veteran Jacquin, in his well-known work on West Indian plants, entitled *Stirpium Americanarum Historia*, as well as by Browne in his *History of Jamaica*; not to mention Swartz, in his *Flora Indica Occidentalis*, who only wanders a little out of the way, to adopt some of Thunberg's alterations. We cannot but observe, that in the very department of botany in which he has most signalized himself, and with which he is most philosophically conversant, the *Orchideæ*, he totally rejects the ideas of Thunberg.

"If we now turn our eyes to the oriental world, we shall find that the seeds of Linnæan botany, sown by Kœnig, have sprung up and produced successive harvests among the pious missionaries at Tranquebar, who still continue to interweave a sprig of science, from time to time, among their amaranthine wreaths which are not of this world. India too has long possessed a practical botanist of indefatigable exertion and ardour, who has thrown more light upon its vegetable riches, with the important subject of their qualities and uses, than any one since the days of Rheede and Rumphius. It is scarcely necessary to name Dr Roxburgh, whose recent loss we deeply lament, and whose acquisitions and learned remarks are given to the world by the munificence of the East India Company, in a style which no prince has ever rivalled.² That enthusiastic admirer of nature, Colonel Hardwicke, and the learn-

East Indies.

¹ Humboldt's splendid work, *Nova Genera et Species Plantarum Americae Æquinoctialis*, in seven volumes, containing several hundred plates, and descriptions of some thousands of new species, was completed in 1825. Since 1816 many other works on the plants of South America have been published, particularly illustrative of the Flora of Brazil. Of these, Pohl's, Martius', and St Hilaire's, are the most eminent.

² From the period in which the East India Company saw its sovereignty established in India with some security, it undertook, both for its own interest and that of humanity, as much as it possibly could, the promotion of the study and culture of the vegetables of that vast country. It, in consequence, directed its attention to the establishment of the Botanic Garden of Calcutta; and it was in March 1768, and under the direction of Colonel R. Kydd, that this garden commenced. A correspondence with all the Europeans settled in various parts of India speedily enriched it with some very precious plants, and there were in it about three hundred species when Dr Roxburgh took the superintendence, in the autumn of 1793. This botanist obtained new and more active correspondents, and visited personally the coast of Coromandel, and some other provinces of British East India. He succeeded in collecting together 3500 species into the garden, and of this number 1500 were previously unknown, but described by him. Such at least we learn from the catalogue of the garden, printed in 1814, at Serampore, by the care of Dr Carey, the friend of Roxburgh. This catalogue appeared in a very condensed shape; it makes known the botanical name, the Indian appellation, the locality, the time of introduction, and the period of inflorescence and fructification, of each plant; it is terminated by an appendix containing a list of other Indian plants, known to the author, but not then under cultivation. Roxburgh sent from time to time to the Company a great number of drawings and descriptions, and from these a selection was made and published under the direction of Sir Joseph Banks. This splendid work, the *Plants of Coromandel*, gives the history and coloured figure of 300 of the most beautiful or most useful of the Indian vegetables. But the very magnificence of this work placed limits to it, and therefore Dr Roxburgh projected a Flora of the East under a more simple form; unfortunately, however, his health forced him to leave India and return home in 1814. His *Indian Flora* was nevertheless not lost to science; Dr Carey published two volumes of it at Serampore, and added to those described by Roxburgh, such as were more lately discovered, both by himself and by Dr Wallich, Jack, and other botanists of British India. This only contains the first five classes of Linnæus.

After the death of Roxburgh, the management of the garden of Calcutta was intrusted to Dr Wallich, whose talents and activity, under the auspices of the Company, have raised the establishment to a high degree of prosperity. More than three hundred persons are employed in the garden, so that the naturalisation of useful objects, and preservation for study of the rare productions of the different parts of India, are equally attended to. Many assistants traverse the country at the expense of the Company, and, with unwearied zeal continue to enrich the garden and the herbarium. Dr Wallich himself travelled in 1820 throughout Nepaul, which, situated at the foot of the great mountains of Himalaya, presents a vegetation of a very different nature from that of Bengal. Since then, notwithstanding the severe disorders brought on by fatigue and the climate, he has visited Penang, Singapore, the kingdom of Ava, and several other parts of India; in addition, he sent collectors into various districts to which he could not go in person; so that, by these different means, a very considerable number of vegetables has been amassed. Descriptions of several of these have been given in the *Prodromus Floræ Nepalensis* of Don, and in other publications of a more general nature published in Europe. Wallich himself, as has been said, inserted many of his discoveries into the *Flora Indica*, and has besides commenced two other works for the purpose of making them better known. The one is the *Tentamen Floræ Nepalensis illustratæ*, which presents a detailed description and a lithographic figure of the principal plants of that country. Two numbers have appeared, each of twenty-five plates; which, in addition to their botanical interest, deserve to be noticed, as being the first attempts at lithographic botanical plates in India, and executed by

Taxonomy.

ed botanist Dr Francis Buchanan, have also contributed greatly to increase our knowledge of Indian botany. The latter has enjoyed the advantage of investigating, for the first time, the remote and singular country of Nepaul, so prolific in beautiful and uncommon plants, that few parts of the world can exceed it; and yet meeting, in several points, not only the floras of the lower regions and islands of India, but those of Japan, China, and even Siberia. The only systematic work on East Indian plants, is the *Flora Indica* of Burmann, which is classed according to the Linnæan artificial method. We cannot but wish that it were more worthy of the system or the subject; yet, as a first attempt, it deserves our thanks. In speaking of Indian botany, shall we withhold our homage from that great and sublime genius Sir William Jones, who honoured this study with his cultivation, and, like every thing else that he touched, refined, elevated, and elucidated it? No man was ever more truly sensible of the charms of this innocent and elegant pursuit; and whenever he adverted to it, all the luminous illustrations of learning, and even the magical graces of poetry, flowed from his pen.

South Seas.

"But we must extend our view beyond the utmost bounds of India, and, of the then discovered world, to trace the steps of those adventurous circumnavigators who sought out, not only new plants, but new countries, for botanical examination. The names of Banks and Solander have, for nearly half a century, been in every body's mouth. Their taste, their knowledge, their liberality, have diffused a charm and a popularity over all their pursuits; and those who never heard of botany before, have learned to consider it with respect and admiration, as the object to which a man of rank, riches, and talents, devoted his life and his fortune; who, while he added, every season, something of novelty and beauty to our gardens, gave the bread-fruit to the West Indies, and was ever on the watch to prompt or to further any scheme of public advantage.¹ With the recollection of such men must also be associated the names of the learned Forsters, father and son, of Sparrmann, and of Menzies, who have all accomplished the same perilous course, and enriched their beloved science. The cryptogamic acquisitions of the latter in New Zealand prove him to have attended to that branch of botany with extraordinary success, and at the same time evince the riches of that remote country. Indeed, it appears that any country proves rich, under the inspection of a sufficiently careful investigator. The labours of these botanists have all been conducted according to the principles and classification of Linnæus. Forster, under Sparrmann's auspices, has judiciously pointed out, and attempted to remedy, defects which their peculiar opportunities enabled them to discover, but with no invidious aim. They laboured, not to overthrow or undermine a system, which they found on the whole to answer the purpose of readily communicating their discoveries, but to correct and strengthen it for the advantage of those who might come after them. It is much to be lamented that,

except the *Nova Genera Plantarum*, we have as yet so short and compendious an account of the acquisitions made in their voyage. To the technical history of these, however, the younger Forster has commendably added whatever he could supply of practical utility, and has thus given us all the information within the compass of his means.

"Long since the voyages of these celebrated naturalists, the same remote countries have been visited, in our own days, by two learned botanists more especially; these are M. Labillardière, and Mr Brown, librarian of the Linnæan Society. The former has published an account of the plants of New Holland, in two volumes folio, with fine engravings; the latter has favoured the botanical world with one volume of a most acute and learned *Prodromus* of his discoveries. As his voyage was made at the public expense, we may trust that the government will consider itself as bound to enable him to publish the whole of his acquisitions, in such a manner as to be generally useful. His own accuracy of observation, illustrated by the drawings of the inimitable Bauer, cannot fail to produce such a work as, we will venture to pronounce, has never been equalled. M. Labillardière has disposed his book according to the system of Linnæus; a rare example in France, where any thing not French usually comes but ill recommended. Mr Brown, on the other hand, has written his *Prodromus*, at least, on the principles of classification established by the celebrated Jussieu, the great champion of a natural system of his own. On this subject we postpone our remarks for the present. Before we can enter on the subject of natural classification, it is necessary to consider the state and progress of botany, for some years past, in the schools, and among the writers, of Europe.

"Sweden has continued to maintain her long established rank in the several departments of natural science, nor has Denmark been behind-hand with her neighbour and ancient rival. The son and successor of the great Linnæus endeavoured to follow his father's steps, and was ambitious of not being left very far in the rear; a commendable aim, which his short life, to say nothing of his talents or experience, disabled him from accomplishing. He completed and gave to the world, the unfinished materials which his father had left, for a supplement to his *Species Plantarum* and *Mantissæ*; and having enriched the book with many communications of Thunberg and others, as well as a number of original remarks, he felt a strong desire, not altogether unpardonable, of being thought the principal author of the work. All uncertainty on this subject, wherever other helps fail, is removed by the original manuscript of the *Supplementum Plantarum* in our possession. Ehrhart superintended the printing of this work, and made some alterations in the manuscript, traces of which are perceptible in the affected Greek names given to some species of *Carex*, *Mespilus*, &c., as well as in their sesquipedalian specific characters. But he had

native draughtsmen. The other work by Dr Wallich, much more splendid than the preceding, is destined to present the history and coloured figures of the rarer plants of Asia. This, the *Planta Asiatica rariores*, will form three volumes.

Besides, Roxburgh and Wallich, there are others who have been patronized by the Company. Koenig, Heyne, Carey, Patrick Russel, Rottler, Klein, Wight, Jack, Finlayson, &c. have traversed different parts of India with the view of studying its vegetation. For about half a century, all the collections of dried plants have been transmitted to England, and preserved in the Company's museum; and the immensity of these materials has made the Directors perceive that they would be useless without the co-operation of many naturalists. By a decision remarkable for its liberality, the Court of Directors has, therefore, lately given instructions to Dr Wallich, at present in London, to distribute these precious collections among the principal botanists of the present day; and the East India Company has thus acquired the most honourable claims on the gratitude of the men of science of every country. But if the thanks of naturalists be due to the Company in the first place, they are scarcely less so to Dr Wallich, who superintends the operation. Far from profiting by his situation to reserve for himself the publication of so much riches, he merely wishes to distribute them among others in the manner which he conceives most useful for the progress of natural history. His time in England, which he has a right to devote to his private affairs, and his valuable notes, are wholly at the service of others.

¹ Sir Joseph died on the 19th of March 1820. See Article BANKS, SIR JOSEPH.

Taxono-
my.

introduced his own new genera of Mosses; which the younger Linnæus thought so alarming an innovation, that he ordered the sheet containing these matters to be cancelled. We are possessed of a copy, which shows the genera in question to be almost all well founded, and what are now, under Hedwig's sanction, generally received, though by other names. The descriptions of Ehrhart are precise and correct, though his terminology is exceptionable, being full of innovations and crabbed expressions. Two years, almost immediately preceding the death of the younger Linnæus, were spent by the latter in visiting England, France, and Holland, and were employed to very great advantage, in augmenting his collections of natural productions, as well as his scientific skill. During this tour he attached himself strongly, through the medium of his old friend Solander, to Sir Joseph Banks; and, while in France, he almost planted, or at least greatly advanced, a Linnæan school in that kingdom. He had scarcely resumed his professorial office at home when he was unexpectedly taken off, by an acute disease, in his forty-second year. Of the talents and performances of his successor Thunberg, who still with honour fills the chair of the Rudbecks and the Linnæi, we have already spoken. Dr Swartz is the Bergian professor of botany at Stockholm. The *Transactions* of the Upsal Academy, founded by the younger Rudbeck, are continued occasionally; and those of the Stockholm Academy, whose foundations were laid by Linnæus, are published regularly. Both are from time to time enriched with botanical communications worthy of the pupils of so illustrious a school. A veteran in botanical science, Professor Retzius, still presides at the university of Lund. The worthy and accurate Afzelius, well known in England, who accomplished a hazardous botanical expedition to Sierra Leone, is the coadjutor of Professor Thunberg; and the difficult subject of Lichens, under the hands of Dr Acharius, has become so vast and so diversified as to be almost a science of itself.

“Denmark has always possessed some acute and learned botanists, and has, more than most other countries, been supplied with dried specimens of plants, as an article of commerce, from her West or East Indian establishments. Oeder, the original author of the *Flora Danica*, and Müller its continuator, have distinguished themselves; but their fame is inferior to that of the late Professor Vahl, who studied under the celebrated Linnæus, and is the author of several excellent descriptive works. He undertook no less than a new *Species*, or, as he entitled it, *Enumeratio Plantarum*; an admirable performance, cut short by his death at the end of the second volume, which finishes the class and order *Triandria Monogynia*. It is almost superfluous to mention, that Afzelius and Retzius, as well as Vahl, in all they have given to the world, have followed the system of their great master. The *Flora Danica*, chiefly a collection of plates, with few synonyms and no descriptions, has come forth, from time to time, for above fifty years past, in fasciculi, without any order, and is still incomplete. It was undertaken by royal command, and, in a great measure, at the sovereign's expense, though regularly sold, except some copies presented to certain distinguished men, as Linnæus.

“After the example of Denmark, Sweden, &c. Russia has been desirous of promoting, throughout its vast dependencies, an attention to natural knowledge. Nor was any country ever more fortunate in the possession of an active and intelligent naturalist. The celebrated Pallas successfully devoted a long life to these pursuits, and to

Taxono-
my.

the communication of his discoveries and observations. He prompted the Empress Catharine to offer an unlimited sum for the museum, library, and manuscripts of Linnæus; but, fortunately for their present possessor, the offer was made too late. A *Flora Rossica*, on the most magnificent scale, was undertaken by Pallas; his imperial mistress proposing to defray the cost of the whole undertaking, not merely for sale, but for gratuitous presentation, on the most princely scale, to all who had any taste or ability to make use of the book. This well-intended munificence was the cause of the ruin of the project. The first half volume was bestowed as the empress intended. But the second part, instead of following the destination of the first, got into the hands of interested people, who defeated the liberal designs of their sovereign, misapplied her money, and by the disgust and disappointment which ensued, prevented the continuance of the work. Those who wished to complete their sets, or to obtain the book at all, were obliged to become clandestine purchasers, buying as a favour, what they ought to have received as a gift; and were, moreover, like the writer of this, often obliged to receive imperfect copies. In like manner the intentions of the great Howard, respecting his book on prisons, were rendered ineffectual by the disgraceful avarice of certain London booksellers, who immediately bought up, and sold at a greatly advanced price, the whole edition, which its benevolent author had destined to be accessible to every body at an unusually cheap rate. These examples, amongst others, show that it is the most difficult thing in the world to employ patronage, as well as gratuitous charity of any kind, to real advantage, except under the guidance of the most rigorous discretion. ‘All that men of power can do for men of genius,’ says Gray, if we recollect aright, ‘is to leave them at liberty, or they become like birds in a cage,’ whose song is no longer that of nature and enjoyment. The great and the affluent may foster and encourage science and literature, by their countenance, their attention, and a free, not overwhelming, liberality; but when princes become publishers of books, or directors of academies, they generally do more harm than good. They descend from their station, and lose sight perhaps of their higher and more peculiar duties, which consist in promoting the general prosperity, peace, and liberty of their subjects, under the benign influence of which, every art, science, or pursuit, that can be beneficial to mankind, is sure to flourish without much gratuitous assistance.

“Several of the immediate scholars of the illustrious of Germany, Swedish naturalist were planted in different parts of Germany, many. Murray, to whom he intrusted the publication of that compendious volume entitled *Systema Vegetabilium*, and who printed two successive editions of the work, was seated as Professor at Göttingen. Giseke was established at Hamburg, and, after the death of Linnæus, gave to the world such an edition as he was able to compile, from his own notes and those of Fabricius, of the lectures of their late preceptor, on the natural orders of plants. His ideas on this subject Linnæus himself always considered as too imperfect to be published, except in the form of a sketch or index, at the end of his *Genera Plantarum*. The venerable patriarch, Professor Jacquin, still survives at Vienna, where he and his worthy son have enriched botany with a number of splendid and useful works. They have given to the public several labours of the excellent practical botanist Wulfen, and others, which might, but for their encouragement, have been lost. The highly va-

¹ At the present day, Sweden has to boast of Agardh and Fries, the former of whom has published many erudite works on the *Alga*, the latter on *Fungi*.

Taxonomy.

luable publication of Host on grasses is conducted on the plan of Jacquin's works. His *Synopsis* of Austrian plants is an excellent *Flora*, disposed according to the sexual system; as is the more ample *Tentamen Floræ Germanicæ* of the celebrated Dr Roth, one of the best practical European botanists, and more deeply versed than most others in cryptogamic lore. The best Linnæan *Flora*, as far as it goes, that the world has yet seen, we speak it without any exception, is the *Flora Germanica* of Professor Schrader of Göttingen, the first volume of which, comprising the first three classes of the sexual system, was published in 1806. The correct distinctions, well-digested synonyms, and complete descriptions, of this work, are altogether unrivalled. If the whole should be equally well executed, for which the longest life would be scarcely sufficient, it must ever be the standard book of European botany. Its descriptions of grasses are worthy to accompany the exquisite engravings of the same tribe from the hand of Leers, published at Herborn in 1775, which excel every botanical representation which we have yet examined. They will bear, and indeed they require, the application of a magnifying-glass, like the plants themselves. The purchaser of this little volume must however beware of the second edition, the plates of which are good for little or nothing. The name of Schrader has long been distinguished in cryptogamic botany. In this pursuit, the industrious and accurate botanists of Germany, shut out from extensive opportunities of studying exotic plants, have had full scope for their zeal and abilities. In this field the Leipsic school has distinguished itself. Here the great Schreber first began his career with some of the most perfect cryptogamic works, especially on the minute genus *Phascum*. Here the same author published his excellent *Flora Lipsiensis*, his laborious practical work on Grasses, and finally his improved edition of the *Genera Plantarum* of his friend Linnæus. But, above all, Leipsic is famous for being the residence of Hedwig, whose discoveries relative to the fructification and generic characters of Mosses form an era in botanic science. Under the hands of such an observer, that elegant tribe displays itself with a degree of beauty, variety, and singularity, which vies with the most admired herbs and flowers, and confirms the Linnæan doctrine of impregnation, which the more obvious organs of the latter had originally taught. Nor must we, in speaking of cryptogamic plants, neglect here to record the names of Weiss, Weber, Mohr, Schmidel, Esper, and especially Hoffmann; the plates of the latter, illustrating the Lichen tribe, are models of beauty and correctness. His *Flora Germanica* is a most convenient and compendious manual, after the Linnæan system. *Fungi* have been studied in Germany with peculiar care and minuteness. The leading systematic author in this obscure tribe, Persoon, was indeed born of Dutch parents, at the Cape of Good Hope; but he studied and published at Göttingen. Two writers of the name of Albertini and Schweiniz have published the most minute and accurate exemplification of this natural order, in an octavo volume, at Leipsic, in the year 1805, comprising the *Fungi* of the district of Niski in Upper Lausatia. If their figures are less exquisitely finished than Persoon's, or less elaborately detailed than Schrader's, their descriptions make ample amends.

"The German school of botany has for a long period been almost completely Linnæan. This however was not always the case; for, in the earlier part of his career, the learned Swede was attacked more repeatedly and severely from this quarter of the world than from any other; his ridiculous critic Siegesbeck of Petersburg excepted, who would not admit the doctrine of the sexes of plants, because the pollen of one flower may fly upon another,

and his purity could not bear the idea of such adultery in nature. Numerous methods of arrangement appeared in Germany, from the pens of Heister, Ludwig, Haller, and others, and even Schreber adopted a system like some of these in his *Flora* above mentioned. It would be to no purpose now to criticise these attempts. They cannot rank as natural systems, nor have they the convenience of artificial ones. Part of their principles are derived from Linnæus, others from Rivinus. Their authors were not extensively conversant with plants, nor trained in any sound principles of generic discrimination or combination. They set off with alacrity, but were soon entangled in their own difficulties, and were left by Linnæus to answer themselves or each other. We here mention these learned systematics; for learned they were thought by themselves and their pupils, merely because they will scarcely require animadversion when we come to canvass the great question of natural and artificial classification, they having had no distinct ideas of a difference between the two. Hedwig used frequently to lament that his preceptor Ludwig had never perfected his system of arrangement; but from what he has given to the world, we see no great room to suppose that he had any thing very excellent in reserve. Unexecuted projects are magnified in the mists of uncertainty. We have ventured elsewhere, in a biographical account of Hedwig, to remark, that even that ingenious man 'did not imbibe, under Ludwig, anything of the true philosophical principles of arrangement, the talents for which are granted to very few, and are scarcely ever of German growth. We mean no invidious reflections on any nation or people. Each has its appropriate merits, and all are useful together in science, like different characters on the theatre of human life.'

"Germany may well dispense with any laurels obtained by the very secondary merit of speculative schemes of classification, when she can claim the honour of having produced such a practical observer as Gärtner. This indefatigable botanist devoted himself to the investigation of the fruits and seeds of plants. Being eminently skilled in the use of the pencil, he has, like Hedwig, faithfully recorded what he no less acutely detected. The path he struck out for himself, of delineating and describing in detail, with magnified dissections, every part of the seed and seed-vessel of each genus within his reach, had never been explored before in so regular and methodical a manner. Botanists of the Linnæan school are justly censurable for having paid too little attention to the structure of these important parts, in their generic characters. Indeed it may be said, that if they were able to establish good genera without them, and, after the example of their leader, merely preferred the more obvious and distinct organs, when sufficient for their purpose, their conduct was justifiable. If generic principles be natural and certain, it matters not on what parts of the fructification they are founded; nor is the inflorescence, or even the herb or root, rejected by sound philosophers, but because they are found to lead only to unnatural and uncertain characters. It is therefore extremely to the honour of Linnæus, Gärtner, and Jussieu, that their conceptions of genera are almost entirely the same. They meet in almost every point, however different the paths by which they pursue their inquiries. Their labours illustrate and confirm each other. Even Tournefort, who conceived so well, on the whole, the distinctions of genera, which he could but ill define, receives new strength from their knowledge, which does not overturn his imperfect performances, but improve them. The accurate student of natural genera cannot fail to perceive, that where Gärtner differs from Linnæus, which is but in a very few material instances, such as his numerous subdivision of the genus *Fumaria*, and his dis-

Taxonomy.

Taxono-
my.

tribution of the compound flowers, it arises from his too intent and exclusive consideration of one part of the fructification, instead of an enlarged and comprehensive view of the whole. In other words, he neglects the Linnæan maxim, that 'the genus should give the character, not the character the genus.' Such at least appears to us the case in *Fumaria*.¹ In the syngenesious family, being so very natural in itself, the discrimination of natural genera becomes in consequence so difficult, that Gærtner and Linnæus may well be excused if they do not entirely agree; and they perhaps may both be satisfied with the honour of having collected materials, and disposed them in different points of view, for the use of some future systematist, who may decide between them. However exact Gærtner may have been in discriminating the parts of seeds, we believe him to have been mistaken in distinguishing the *vitellus* as a separate organ, distinct in functions from the *cotyledons*. His readers will also do well, while they profit by his generally excellent principles, not to admit any of his rules as absolute. They may serve as a clue to the intricacies of nature, but they must not overrule her laws. Still less is our great carpologist to be implicitly followed in physiological doctrines or reasonings; witness his feeble and incorrect attack on Hedwig's opinions, or rather demonstrations, respecting the impregnation of Mosses. His criticisms of Linnæus are not always marked with that candour which becomes a disinterested lover of truth and nature; nor can we applaud in general his changes of nomenclature or of terminology, especially when he unphilosophically calls the *germen* of Linnæus the *ovarium*, a word long ago rejected, as erroneous when applied to plants.² These however are slight blemishes in a reputation which will last as long as scientific botany is cultivated at all. Botanists can now no longer neglect, except at their own peril, the parts which Gærtner has called into notice, and to the scrutiny of which, directed by his faithful guidance, the physiologist and the systematist must often in future recur.

f Prussia,

"We shall close this part of our subject with the mention of the Berlin school, where Gleditsch, who, in 1740, repelled the attacks of Siegesbeck on Linnæus, was professor, and published a botanical system, founded on the situation, or insertion, of the stamens; the subordinate divisions being taken from the number of the same parts; so that it is, in the latter respect, a sort of inversion of the Linnæan method. In the former, or the outline of its plan, the system of Gleditsch is in some measure an anticipation of that of Jussieu. Berlin has of late been much distinguished for the study of natural history, and possesses a society of its own, devoted to that pursuit. Its greatest ornament was the late Professor Willdenow, who, if he fell under the lash of the more accurate Afzelius, is entitled to the gratitude of his fellow-labourers, not for theoretical speculations, but for the useful and arduous undertaking of a *Species Plantarum*, on the Linnæan plan, being indeed an edition of the same work of Linnæus, enriched with recent discoveries. This book, left unfinished at the end of the first order of the *Cryptogamia*, by the death of the editor, wants only a general index to render it sufficiently complete. The *Musei*, *Lichenes*, and *Fungi*, are systematically treated in the separate works of writers devoted to those particular, and now very extensive, subjects, from whom Willdenow could only have been a compiler. With the *Filices*, which he lived to publish, he was practically conversant. His inser-

tion of the essential generic characters, throughout these volumes, is a useful addition, and has now become necessary in every similar undertaking.

Taxono-
my.

"Little can be said of Holland in this review of the botanical state of Europe for a few years past. The Leyden garden has always been kept up, especially during the life of the late Professor David Van Royen, with due care and attention: we know little of its fate in the subsequent convulsed state of the country. Botany has long been on the decline at Amsterdam, though we are indebted to that garden for having first received, and afterwards communicated to other countries, such acquisitions of Thunberg in Japan as escaped the perils of importation.

"The botany of Switzerland may, most commodiously, of Switzerland be considered in the next place. Here, in his native land, country, the great Haller, after a long residence at Göttingen, was finally established. Its rich and charming *Flora* has been illustrated by his classical pen, with peculiar success. Every body is conversant with the second edition of his work, published in 1768, in three volumes folio, and entitled *Historia Stirpium Indigenarum Helvetiæ*, with its inimitable engravings, of the *Orehis* tribe more particularly. But few persons who have not laboured with some attention at the botany of Switzerland, are aware of the superior value, in point of accuracy, of the original edition of the same work, published in 1742, under the title of *Enumeratio Methodica Stirpium Helvetiæ Indigenarum*. This edition is indispensable to those who wish fully to understand the subject, or to appreciate Haller's transcendent knowledge and abilities. These works are classed after a system of his own, intended to be more consonant with nature than the Linnæan sexual method. We can scarcely say that it is so, on the whole; nor is it, on the other hand, constructed according to any uniformity of plan. The number of the stamens, compared with that of the segments of the corolla, or its petals, regulate the characters of several classes, and these are artificial. Others are assumed as natural, and are for the most part really so; but their characters are frequently taken from Linnæus, even from his artificial system, as the *Cruciatæ* and the *Apetalæ*. Lord Bute has well said, that Haller was a Linnæan in disguise. His classification, however, was merely intended to answer his own purpose with respect to the Swiss plants; for he was not a general botanist, nor had he a sufficiently comprehensive view of the subject to form a general system, or even to be aware of the difficulties of such an undertaking. He ought not therefore to be obnoxious to criticism in that view. His method has served for the use of his scholars, as the Linnæan one serves English botanists, by way of a dictionary. Some such is necessary; and those who should begin to decide on the merits of a system, before they know plants, would most assuredly be in danger of appearing more learned to themselves than to others. We cannot exculpate Haller from some degree of prejudice in rejecting real improvements of Linnæus, which are independent of classification; such as his trivial or specific names, by which every species is spoken of at once, in one word, mostly so contrived as to assist the memory, by an indication of the character, appearance, history, or use, of the plant. What did the great Swiss botanist substitute instead of this contrivance? A series of numbers, burthensome to the memory, destitute of information, accommodated to his own book only, and necessarily liable to

¹ Most modern botanists view the Linnæan genus *Fumaria* as a natural order, and have therefore properly adopted Gærtner's divisions as distinct genera.

² Notwithstanding the above opinion to the contrary, *ovarium* is now generally adopted instead of *germen*.

Taxono-
my.

total change on the introduction of every newly-discovered species! At the same time that he rejected the luminous nomenclature of his old friend and fellow-student, who had laboured in the most ingenuous terms to deprecate his jealousy, he paid a tacit homage to its merit, by contending that the honour of this invention was due to Rivinus. In this he was not less incorrect than uncandid, the short names of Rivinus being designed as specific characters, for which purpose Haller knew, as well as Linnæus, that they were unfit. Useful specific characters he himself constructed on the plan of Linnæus, with some little variation, not always perhaps for the better as to strictness of principle, but often strikingly expressive. Here, as in every thing connected with practical botany, he shines. The most rigid Linnæan, whose soul is not entirely shrivelled up with dry aphorisms and prejudice, must love Haller for his taste and enthusiasm, and the Flora of Switzerland as much for his sake as its own. No wonder that his pupils multiplied, and formed a band of enthusiasts, tenacious of even the imperfections of their master. The line of demarcation is now no longer distinctly drawn between them and the equally zealous scholars of the northern sage. The amiable and lamented Davall strove to profit by the labours of both. The Alpine botanists of France and Italy have served to amalgamate the Swedish and the Helvetian schools. The Flora of Dauphiné by Villars is nearly Linnæan in system; and the principles of the veteran Bellardi of Turin are entirely so, though, in some of his publications, he has been obliged to conform to the method of his preceptor, the venerable Allioni, who, in spite of all remonstrance, had the ambition of forming a system of his own. His *Flora Pedemontana* is disposed according to this system; an unnatural and inconvenient jumble of the ideas of Rivinus, Tournefort, and others. This work is also faulty in the neglect of specific definitions, so that its plates and occasional descriptions are alone what render it useful; nor would it, perhaps, be consulted at all, but for the uncommon abundance of rare species.¹

of Italy,

"We may glance over the botany of Italy, to whose boundaries we have thus been insensibly led, as the traveller takes a bird's-eye view of its outstretched plains from the lofty summits of the Alps. We may pass from Turin to Naples without meeting with any school of distinction. The northern states are not without their professors and patrons of botany; nor are their nobles destitute of taste, in various branches of natural knowledge. The names of a Castiglione of Milan, a Durazzo and Dinegro of Genoa, and a Savi of Pisa, deserve to be mentioned with honour, for their knowledge and their zeal. The unfortunate Cyrillo, and his friend Pacifico, of Naples, were practical botanists. There is also a rising school, of great promise, at Palermo. But since the time of Scopoli, Italy has contributed little to our stock of information; nor are the latter publications of this eminent man, while he resided at Pavia, commensurate in importance or merit with those earlier ones, the *Flora* and the *Entomologia Carniolica*, which have immortalized his name. Scopoli, who at first adopted a system of his own, had the sense and liberality, in his second edition, to resign

it in favour of what his maturer experience taught him to prefer, the sexual system of Linnæus.²

"Spain and Portugal claim our attention; the former for being the channel through which the gardens of Europe have, for some years past, been enriched with many new Mexican and Peruvian plants, and likewise as the theatre of the publication of some important books relative to the botany of those countries. In speaking of American botany, we have mentioned the *Flora Peruviana*, the authors of which, Ruiz and Pavon, rank deservedly high for their industry and knowledge. The late Cavanilles, resident at Madrid, has also communicated to the learned world much information, from the same source. Spain seems anxious to redeem her reputation, which suffered so much from the neglect, or rather persecution, of the truly excellent but unfortunate Dombey, who, like many other benefactors of mankind, was allowed to make all his exertions in vain, and finally perished unknown, in the diabolical hands of English slave-dealers at Montserrat.³ Portugal is most distinguished at home by the labours of a learned benedictine, Dr Felix Avellar Brotero, author of a *Flora Lusitana*, disposed after the Linnæan method, reduced entirely to principles of number; and abroad by the valuable work of Father Loureiro, entitled *Flora Cochinchinensis*, in which the plants of Cochinchina, and of the neighbourhood of Canton, are classed and defined in the Linnæan manner, with valuable descriptions and remarks. It is undoubtedly a disgrace to the possessors of such a country as Brazil, that they have not derived from thence more benefit to the world or to themselves from its natural productions. But they are satisfied with what the bowels of the earth afford, and they neglect its more accessible, though perhaps not less valuable treasures. The jealousy and innumerable restrictions of their government render what they possess as useless to all the world as to themselves. A genius of the first rank in natural science, as well as in every thing which his capacious mind embraced, has arisen in Portugal, and has been domesticated in the schools of Paris and London, the amiable and learned Correa de Serra. What little impulse has been given to literature in Portugal, and particularly the foundation of a Royal Academy of Sciences, is owing to him; and though his name has chiefly appeared in the ranks of botanical science in an incidental manner, no one possesses more enlarged and accurate views, or more profound knowledge, of the subject.

"In the extensive, though incomplete, review which we English have undertaken of the recent history of botanical science, and the individual merits of particular writers have chiefly hitherto been detailed and compared. The most difficult part of our task perhaps still remains, namely, to contrast and appreciate the influence and the merits of two great and rival nations, in the general school of scientific botany; to consider the causes that have led to the particular line which each has taken; and to compare the success, as well as to calculate the probable future consequences, of their respective aims. England and France have, from the time of Ray and Tournefort, been competitors in botanical fame, because each was ambitious of supporting the credit of the great man she had produced. This contest,

and Portu-
gal.

¹ Geneva is celebrated at the present day as the residence of Professor De Candolle. This distinguished botanist, in addition to many other works of scarcely inferior merit, published, in 1818 vol. 1st, and in 1821 vol. 2d, of a *Regnum Vegetabile*, arranged according to the natural system. No more has yet appeared; but in 1824 he commenced a *Prodromus*, or abridgement of what the other was intended to be; and of this four volumes are completed. It is expected to be concluded in a few years.

² Raddi, Tenore, Viviani, and the Sicilian botanist Gussone, had scarcely, at the time when Sir J. E. Smith wrote this, gained sufficient fame to be noticed by him.

³ Had Sir James Smith lived, he would have found occasion to alter the above paragraph. At present there is not one individual deserving the name of botanist in Spain. The last of them, Lagasca, has had all his collections, including what he had amassed for years with a view to publish a Flora of Spain, entirely destroyed, and been obliged himself to take refuge in England.

axono-
my.

Taxono-
my.

however, as far as it regarded theoretical speculations, has entirely subsided on the part of Ray's champions. In practical science, likewise, the admirers of Ray and of Tournefort have shaken hands, like those of every other school. On the subject of system, the question is greatly changed; for though a phoenix has arisen from the ashes of Tournefort, its 'star-like eyes,' darting far beyond all former competition, have been met, if not dazzled, by a new light, rising in full glory from the north; a polar star, which has been hailed by all the nations of the earth.

England.

"The Linnæan system of classification, with all its concomitant advantages of nomenclature, luminous technical definition, and richness of information, was planted, like a fresh and vigorous scion, in the favourable soil of England, already fertilized with accumulations of practical knowledge, about the middle of the last century. If we may pursue the metaphor, the ground was entirely cleared for its reception; for all previous systems had been of confined and local use, the alphabetical index having become the resource of even the most learned, and the pupils of Ray being held to his method of classification rather by their gratitude for his practical instruction, than any other consideration. Accordingly we have, in our own early progress, before they were all, as at present, swept off the stage, found them rather contending for his nomenclature, imperfect as it was, because they were habituated to it, than for his system, of which it was evident they had made little use. Hence the first attempt in England to reduce our plants to Linnæan order, made by Hill, was chiefly a transposition of Ray's *Synopsis* into the Linnæan classes; the original nomenclature being retained, while the specific names of the *Species Plantarum* were rejected.

Norwich.

"Hill's imperfect performance was superseded by the more classical *Flora Anglica* of Hudson, composed under the auspices and advice of the learned and ingenious Stillingfleet, in which the botany of England assumed a most scientific aspect, and with which all the knowledge of Ray was incorporated. At the same time, the principles of theoretical botany, and the philosophical writings of the learned Swede, were studied with no ordinary powers of discrimination and judgment, in a small circle of experienced observers at Norwich. A love of flowers, and a great degree of skill in their cultivation, had been long ago imported into that ancient commercial city, with its worsted manufacture, from Flanders; and out of this taste something like the study of systematic botany had sprung. These pursuits were mostly confined to the humblest of the community, particularly among the then very numerous bodies of journeymen weavers, dyers, and other artisans of a similar description. Towards the middle of the eighteenth century, several of the opulent merchants seem to have acquired, by their intimate connection with Holland, not only the above-mentioned taste for horticulture, but likewise an ambition to be distinguished by their museums of natural curiosities. The former sometimes extended itself, from the flowery parterre and the well-arranged rows of tulips, hyacinths, carnations, and auriculas, into no less formal labyrinths, or perhaps a double pattern of angular or spiral walks, between clipped hedges, exactly alike on each side of a broad gravel walk. Such was the most sublime effort of the art within the compass of our recollection. "Grove" could by no means be said to "nod at grove," for the perpendicular and well-trimmed structure was incapable of nodding; but that "each alley should have a brother" was an indispensable part of the design. Greenhouses of exotic plants, except oranges and myrtles, were at this time scarcely known; and the writer well recollects having seen, with wonder and admiration, above forty years

ago, one of the first African geraniums that ever bloomed in Norwich. If, however, the progress of natural science was slow in this angle of the kingdom, the wealthy manufacturers, become their own merchants, found it necessary to acquire a knowledge of various foreign languages, in order to carry on their wide-extended commerce. In learning French, Italian, Spanish, Dutch, and German, they unavoidably acquired many new ideas. Their sons were sent to the continent, and it were hard, indeed, if many of them did not bring home much that was worth learning. The society of the place, aided by some concomitant circumstances, and the adventitious acquisition of two or three men of singular talents and accomplishments, became improved. A happy mixture of literature and taste for many years distinguished this city above its rivals in opulence and commercial prosperity. Such Norwich has been in our memory; and if its splendour be gone by, a taste for mental cultivation, originating in many of the before-mentioned causes, still remains, and is fostered by the novel pursuits of chemistry and natural history, on which some arts of great importance in the manufactory of the place depend for improvement. We trust the reader will pardon this digression from the subject more immediately before us, to which we shall now return.

"Some of the more learned students of English plants, among the lovers of botany in Norwich, had long been conversant with the works of Ray, and even the *Historia Muscorum* of Dillenius. They were prepared therefore to admire, and to profit by, the philosophical writings of Linnæus. Hence originated the *Elements of Botany*, published in 1775 by Mr Hugh Rose, who was aided in the undertaking by his equally learned friend, the reverend Henry Bryant, of whose acuteness and botanical skill no better proof is wanting, than his having found and determined, nine years before, the minute *Tillæa muscosa*, for the first time in this island. Numerous pupils were eager to improve themselves by the assistance of such masters; and, amongst others, the writer of these pages imbibed, from their ardour and friendly assistance, the first rudiments of a pursuit that has proved the happiness and the principal object of his life.

"London became, of course, the focus of this science, as well as of every other. Of the English universities, Cambridge most fulfilled its duty, in rendering its public establishments useful to the ends for which they were founded and paid. The names of Martyn, both father and son, have long maintained a distinguished rank in botany; and the latter, for many years, has inculcated the true principles of Linnæan science, from the professor's chair. A botanic garden was established by a private individual, Dr Walker, about the period of which we are speaking. A Linnæan *Flora Cantabrigiensis*, by Mr Relhan, has renewed the celebrity of that field in which Ray had formerly laboured; and there has always existed a little community of Cambridge botanists, though fluctuating and varying, according to circumstances. At Oxford, botany, so vigorously established by Sherard and Dillenius, slept for forty years under the auspices of the elder Professor Sibthorp, at least as to the utility of its public foundations. Yet even there the science had many individual cultivators, and if others were forgotten, the name of a Banks ought to render this school for ever celebrated. The younger Professor Sibthorp well atoned for the supineness of his father and predecessor. He published a *Flora Oxoniensis*, and extended his inquiries into the classical scenes of Greece, finally sacrificing his life to his labours, and sealing his love of this engaging study by a posthumous foundation, which provides for the publication of a sumptuous *Flora Græca*, and the subsequent establishment of a professorship of rural economy. Edinburgh, under the aus-

Taxonomy.

pices of Professor Hope, became distinguished for the cultivation of botany as a branch of medical education. The physiology of plants was there taught more assiduously than in almost any other university of Europe; and the Linnæan principles were ably enforced and illustrated, not with slavish devotion, but with enlightened discrimination. Nor must the dissenting academy at Warrington be forgotten, where the distinguished circumnavigator Forster, of whom we have already spoken, was settled. Here many young naturalists were trained. The neighbouring family of the Blackburnes, possessed even to this day of one of the oldest and richest botanic gardens in England, have steadily fostered this and other branches of natural knowledge. The same taste has spread to Manchester, Liverpool, and the country around. Westmoreland, Northumberland, and Durham, have their sequestered practical botanists in every rank of life. Scenes celebrated by the correspondents of Ray are still the favourite haunts of these lovers of nature and science, who every day add something to our information, and to the celebrity of other parts of the same neighbourhood.

London school.

"We must now concentrate our attention to the London school, which for about forty years past has maintained a rank superior to most other seats of botanical science; the more so perhaps from its being founded in total disinterestedness, both with respect to authority and emolument. Truth alone, not system, has been the leading object of this school; unbiassed and gratuitous patronage its support; and a genuine love of nature and of knowledge its bond of union, among persons not less distinguished from each other by character and opinion, than by their different pursuits and various ranks of life. The illustrious Banks, from the time when, after his return from his celebrated and adventurous voyage, he devoted himself to the practical cultivation of natural science for the advantage of others, as he had long pursued it for his own pleasure and instruction, has been the head of this school. Here he fixed the amiable and learned Solander, for the remainder of his too short life. The house of this liberal Mecænas has ever since been, not only open, but in a manner at the entire command of the cultivators and admirers of this and other branches of philosophy; inasmuch as his library and museum have been devoted to their free use; and his own assistance, encouragement, and information are as much at their service as if his fortune and fame had all along depended on their favour. With such an establishment as this, aided by the perpetual resources of the numerous public and private gardens around, botany might well flourish. The liberal spirit of the leaders of this pursuit gave a tone to the whole. The owners of nurseries, though depending on pecuniary emolument for their support, rivalled each other in disinterested communication. The improvement of the science was the leading object of all. One of this latter description took his rank among the literary teachers of botany. Lee's *Introduction* was much approved by Linnæus, whose system and principles it ably exemplifies, and who became the friend and correspondent of its author. Travelling botanists were dispatched under the patronage of the affluent to enrich our gardens from the Alps, the Cape of Good Hope, and the various parts of America. Every new acquisition was scrutinized, and received its allotted name and distinction from the hand of the correct and classical Solander, who one day was admiring with Collinson, Fothergill, or Pitcairn, the treasures of their respective gardens, and another labouring with the distinguished Ellis,

at the more abstruse determination of the intricate family of marine productions, whether sea-weeds, corallines, or shells. His own acquisitions, and those of his friend and patron, in the fairy land of the South Sea Islands, the hazardous shores of New Holland, or the nearly fatal groves and swamps of Java, were at the same time recorded by his pen, as they were gradually perpetuating by the slow labours of the engraver. To this band of zealous naturalists the younger Linnæus was for a while associated, as well as the excellent and zealous Broussonet, who, though not unversed in botany, devoted himself most particularly to the more uncommon pursuit of scientific ichthyology.

"The Banksian school, altogether intent upon practical botany, had adopted the Linnæan system as the most commodious, while it pursued and cultivated the Linnæan principles as the only ones which, by their transcendent excellence, could support the science of botany on a stable foundation. In these Dr Solander was, of course, well trained; and, having added so wide a range of experience to his theoretical education, few botanists could vie with him, who had, as it were, caught his preceptor's mantle, and imbibed, by a sort of inspiration, a peculiar talent for concise and clear definition. Abstract principles of classification, or even such outlines of natural arrangement as Linnæus had promulgated, seem never to have attracted Solander. In following the chain of his ideas, discernible in the materials he has left behind him, one cannot but remark his singular inattention to every thing like botanical affinity, to which the artificial sexual system was, with him, entirely paramount. The genera which, for extemporaneous use, he named with the termination *oides*, comparing each with some well-known genus, till a proper appellation could be selected, are seldom thus compared because of any natural affinity, or even any external resemblance, but because they agree with such in their place in the artificial system, or nearly perhaps in technical characters. A great botanist, therefore, it is evident, may exist, without that vaunted erudition in a peculiar line, which some would have us consider as the only road to knowledge and to fame. We allow that this sort of erudition is now, since the attention it has received from Linnæus, Jussieu, and others, become as indispensable to a good theoretical or philosophical botanist, as is the study of carpology, in consequence of the labours of Gærtner; we only contend that it is possible to know plants extremely well without either.

"The learned Dryander, less skilled than his predecessor the coadjutor of Sir Joseph Banks, in a practical acquaintance with plants, exceeded him in theoretical lore and ingenious speculation, and far excelled every other man in bibliographic information, as well as in the most precise and fastidious exactness relative to every subject within the wide extent of his various knowledge. He furthered, upon principle, and with unwearied assiduity, every object of the noble establishment to which he was devoted; but, like Solander, he now sleeps with his fathers, and his place is supplied by a genius of British growth, who unites talents with experience, and theoretical skill, in the most eminent degree, with practical knowledge.¹

"Although it is almost superfluous to name the most eminent disciples of the London school of botany, it might seem negligent to pass them over without some particular mention. The ardent and ingenious Curtis has left a permanent monument behind him, in the *Flora Londinensis*, to say nothing of the popular *Botanical Magazine*, continued

¹ Since the death of Sir Joseph, his library and herbarium have been deposited in the British Museum, where Mr Brown, to whom Sir James here alludes, has still the unqualified charge of them.

Taxonomy.

Taxonomy.

by his friend Dr Sims. The *Flora Scotica* of Lightfoot first offered, in a pleasing and familiar garb, the botanical riches of that part of the island to its southern inhabitants. The lynx-eyed Dickson, so long and faithfully attached to his constant patron, has steadily traced, through all its windings, the obscure path of cryptogamic botany with peculiar success. No more striking instance can be pointed out, to prove how totally the most consummate practical skill, even in the most difficult part of botany, is independent of theoretical learning. Even those who profit by the certain aids supplied by the discoveries of Hedwig, can with difficulty keep pace with this veteran in their pursuits, who, with conscious independence, neglects all those aids.

Museum and library of Linnæus.

"Just at the time when the school, whose history we are endeavouring to trace, had most firmly established its credit and its utility, a great additional weight was given to England, in the scale of natural science, by the acquisition of the entire museum, library, and manuscripts of the great Linnæus and his son, which came amongst us, by private purchase, in 1784, after the death of the latter. Hence our nomenclature has been corrected, and our knowledge greatly augmented. These collections have necessarily been consulted by most persons about to publish on the subject of natural history, and a reference to them, in doubtful cases, secures a general conformity of sentiment and nomenclature among the botanists of Europe, Asia, and America. We are seldom obliged to waste time in conjecturing what Linnæus, or the botanists with whom he corresponded, meant, for we have before us their original specimens, named by their own hands. An entire London winter was devoted to the almost daily labour of comparing the Banksian herbarium throughout, with that of Linnæus, and to a copious interchange of specimens between their respective possessors, who, with the aid of Mr Dryander alone, accomplished this interesting and instructive comparison. Hence the *Hortus Kewensis* of the lamented Aiton, which was at that period preparing for publication, became much more correct in its names, than it, or any other similar performance, could have been, without this advantage. It could scarcely be expected that Sweden would, unmoved, let the botanical sceptre thus pass from her; but it is much to the honour of the nation, that all her naturalists have ever preserved the most friendly intercourse with us, particularly with the person who deprived them of this treasure. They have not merely pardoned, but publicly sanctioned, the scientific zeal which prompted him to this acquisition, by associating him with all their learned establishments, without any solicitation on his part.¹

Linnæan Society.

"The institution of the Linnæan Society at London in 1788, especially under that name, must be considered as a triumph for Sweden in her turn. By this establishment the intercourse of science is facilitated; essays, which might otherwise have never seen the light, are given to the world; and a general taste for the pleasing study of nature is promoted. Learned and worthy people are thus made acquainted with each other, from the remotest corners of the kingdom, and their information enriches the common stock. The state has given its sanction to this rising establishment. Its publications and its members are spread over the Continent, and other similar institutions have borrowed its name, imitated its plan, and paid respect to its authority. Yet it is not in the name alone of Linnæus, that the members of this society place their confidence; still less do they bow to that name, or to any

Taxonomy.

other, at the expense of their own right of private judgment. Their transactions are open to the pupils of every school, and the observations of every critic, that have any prospect of being useful to the world. The writer of each communication must, of course, be answerable for the particulars of his own performance, but the society is responsible for each being, on the whole, worthy to be communicated to the public. The possession of the very materials with which Linnæus worked, his own specimens and notes, enables us very often to correct mistakes, even of that great man, many of which would be unaccountable without the means of thus tracing each to its source. At the same time, the acquisition of materials to which he never had access, tends to improve and augment the history of what he had left imperfect. His language, his definitions and characters, were, for some time, held so sacred, that they were implicitly copied, even though manifestly inapplicable, in some points, to the objects to which they were referred. Synonyms were transcribed from his works by Rose, Hudson, Curtis, and even Gærtner (we assert it on the positive proof of errors of the press, copied in the transcribing), without reference to the original books, to see whether such synonyms, or their accompanying plates, agreed with the plant under consideration. The example of Dr Solander first led the writer of this to avoid such a negligent and unfaithful mode of proceeding; yet he has ever considered as sacred the very words of Linnæus, where they require no correction. They are become a kind of public property, the current coin of the botanical realm, which ought not, with impunity, to be falsified or adulterated. To them we hope to be pardoned if we apply the words of the poet,

The solid bullion of one sterling line,
Drawn to French wire, would through whole pages shine.

Of this it is needless to quote examples. We must be every day more and more sensible of the value of the Linnæan style, in proportion as the number of those who can attain it is evidently so very small. By the light of our master alone can the science, which he so greatly advanced and refined, be preserved from barbarism, while long and tedious, loose and feeble, ill-contrasted and barbarously-worded definitions, press upon it from various quarters. New terms are invented to express old ideas; names and characters are changed for the worse, to conceal the want of new discoveries; and students are often deterred from adopting real improvements, because they know not which guide to prefer.

"From the combined effects of the various causes which we have endeavoured to trace, the study of botany in England has, for a long period, been almost entirely practical. To determine the particular species intended, in every case, by Linnæus; to distinguish and to describe new ones; to improve scientific characters, and to correct synonyms; these have been the objects of our writers; and hence many publications of great utility, especially a number of critical and descriptive essays, in the Transactions of the Linnæan Society, not unworthy of the school which gave them birth, have enriched the general stock of knowledge. These are the sound fruits of skill and investigation, the solid advantages of real information, applied to practical use. They are independent of theoretical speculation, and will stand unshaken, amidst any possible changes of system. On such principles the *Flora Britannica* has been attempted, and continued as far as the present unsettled state of some of the latter orders, of the last class,

Practical study of botany in England.

¹ It may not, perhaps, be generally known, that Sir James Smith himself was the purchaser. Since his death it has become the property of the Linnæan Society of London, along with all his private collections and library.

Taxono-
my.

will allow.¹ Such impediments, which depend on the difficulties of systematic discrimination, among the Lichens especially, it is hoped will soon be removed. Meanwhile the *English Botany* of the same writer, illustrated by Mr Sowerby's expressive and scientific figures, has finished its course, and formed so nearly complete a body of local botany, as, we believe, no other country has produced. In this the liberal contributions of numerous skilful observers, from the Alpine heights of Scotland to the shores and circumambient ocean of the south, are preserved and recorded; evincing a degree of general inquiry and acuteness, which hardly any nation can rival. The memory of several benefactors to the science, otherwise in danger of passing away, is embalmed in this national work, which serves at once as their botanical testament, and the monument of their fame. Some of our botanists of the present day have thrown great light on several of the most obscure departments of the science; witness Mr Sowerby's work on *English Fungi*; the labours of the learned Bishop of Carlisle on *Carices*, and, in conjunction with Mr Woodward, on *Fuci*; of Mr Dawson Turner on the latter tribe, and on the *Musci* of Ireland; but especially Mr Hooker's inimitable display of the British *Jungermanniæ*.² Nor shall the contributions of a Winch or an Abbot, a Withering, Knapp, Stackhouse, or Vellely, nor the more splendid labours of the indefatigable Lambert, be forgotten. Each, in one way or other, has enlarged the bounds of science, or rendered it easier of access. We cannot, in the compass of our present undertaking, pay the tribute due to every individual, our aim being a general picture of the whole. From what we have said, the zeal with which this lovely science has been cultivated in England, will sufficiently appear. Nor have public lectures or botanic gardens been neglected, in order to render the knowledge of botany as accessible as possible, and to diffuse a taste for its pursuit. The popularity of the study has, at least, kept pace with the means of instruction. The garden and green-house, the woods, fields, and even the concealed treasures of the waters, are now the resource of the young and the elegant, who, in the enjoyment of a new sense as it were, in the retirement of the country, imbibe health, as well as knowledge and taste, at the purest of all sources.

France.

"France alone now remains to be considered, in order to finish the historical picture which we have undertaken of the state of botanical science in Europe. To do justice to this part of our subject, we must turn our attention to times long since gone by, or we shall scarcely render intelligible the state of affairs at present.

Tournefort.

"The great Tournefort, by the force of his character, his general and particular information, the charms of his pen, and the celebrity which his name gave to his country, through the popularity of his botanical system, was so firmly established, in the ideas of the French, as the *Grand Monarque* of botany, that they would have as soon allowed the greatness of Louis XIV. to be questioned, as that of this distinguished philosopher. So beneficial was this partiality, in some respects, that it gave an unprecedented impulse and popularity to the science; so disadvantageous was it in others, that it placed a formidable barrier in the

way of all improvement. Vaillant, the able and worthy pupil of Tournefort, has never been forgiven for speaking, on some occasions, too freely of his master's defects. Hence his own merit has been kept in the back ground. The doctrine of the sexes of plants was discountenanced as long as possible, because it was proved by Vaillant, after having been rejected by Tournefort. Nevertheless, when the good seed of science is once sown, it can hardly be totally suffocated by the impediments of prejudice and ignorant partiality. Practical zeal sprung up by the side of speculative jealousy, and the tares withered, while the profitable plants flourished. Some botanists followed the steps of Tournefort to the Levant, exploring afresh those countries which he has for ever rendered classic ground. Others visited America, which they traversed in different directions. The indefatigable Plumier performed three separate voyages to the western world; and though his discoveries have, in a great measure, suffered shipwreck from tardy and imperfect patronage, as a great part of his collections did by the accidents of nature, yet something of value remains. His *Filices* are enough to insure his perpetual remembrance, and his *Nova Genera* are the basis of our knowledge of generic differences in West Indian plants. Most of all has been distinguished, among the French botanists who succeeded the times of Tournefort and Vaillant, the family of the Jussieus. One of these Jussieus investigated the prolific regions of Peru, and discovered some things which no succeeding traveller has gathered. Other branches of this family, besides being eminent in medical science and practice, have pursued the study of botany with no ordinary success, on the most philosophical principles. Of these the most eminent are the celebrated Bernard de Jussieu, the contemporary of the earlier days of Linnæus; and his nephew Antoine Laurent de Jussieu, the pride and the ruler of systematic botany at present in France. The views and the performances of these great men lead us to a new branch of our subject, which indeed we have had in our contemplation from the beginning of this essay,—the exposition of the principles of a natural scheme of botanical classification, as hinted, and imperfectly sketched, by Linnæus, and brought to the perfection of a regular system by the Jussieus.

"Previous to our entering on this detail, and the remarks to which it will give rise, we must conclude all that belongs to the former part of our undertaking, by giving some account of those botanists who have formed and maintained a Linnæan school in France. We must shelter ourselves under the broad banner of truth when we observe that these have, till very lately, been almost the only French botanists that have supplied us with any practical information; and their labours have been useful in proportion as they have commendably shaken off the prejudices of their predecessors. Of this last proposition Duhamel is a witness, though we may perhaps excite some surprise in classing him among Linnæan botanists. His preface to his *Traité des Arbres* sufficiently shows how fearful he was of being taken for such, and yet how he was held by vulgar prejudice alone, to the nomenclature, or rather the generical opinions of Tournefort. He tells

¹ The *English Flora* was published on the same plan, a short time before the death of the author. This contains none of the Cryptogamia except the Ferns, but a continuation is every day expected from Dr Hooker.

² Dr Hooker, now Professor at Glasgow, is better known throughout the world as the first muscologist of the present age. His *Musci Exotici* and *Muscologia Britannica* are excellent. In a knowledge of Ferns he is also unrivalled, upon which branch, along with Dr Greville, he has published the splendid *Icones Filicum*. But it is not Cryptogamia alone his pencil and pen have illustrated; he has published the *Exotic Flora*, at present continues the *Botanical Magazine*, and is engaged with a *Botanical Miscellany*, *Flora Borcali-Americana*, &c. all of which are accompanied with plates.—Among those who have contributed in this country to illustrate botany by plates, we ought not to omit to mention Mr Lindley, and also Dr Greville, whose delineations of Cryptogamic subjects, particularly of Fungi, must always render his *Scottish Cryptogamic Flora* a standard work. There are other botanists, likewise, who equally deserve notice, although they be not gifted with the use of the pencil: Mr David Don has contributed much to the page of botany, but who has not heard of Mr Robert Brown, "*Botanicorum facile princeps*?"

axono-

us, while he adopts these, that his judgment went with Linnæus, whom he follows in all new discoveries. The plan of his book, confined to hardy trees and shrubs, justifies his use of an alphabetical arrangement, in preference to any system, unless he had thought sufficiently well of Tournefort's to prefer that. But he has prefixed to his work, as a practical method of discovering scientifically what it contained, no other than a sexual classification. His practical botany was so limited, being entirely subservient to his great objects of forest planting and vegetable physiology, that he had no attention to spare for the consideration of methodical systems. Accordingly, he tells us, that some such is necessary for the use of botanists, especially of those who explore the productions of foreign countries; but whether the method of Ray, Tournefort, Boerhaave, Van-Royen, Linnæus, or Bernard de Jussieu be adopted, is of no importance. Six years before Duhamel's work came out, Dalibard had published, in 1749, his *Floræ Parisiensis Prodromus*, according to the Linnæan system.

"It has always appeared to the writer of this, from the conversation and writings of French botanists, that the judgment of the learned Le Monnier, and the countenance of his patron the Duke d'Ayen, afterwards Marechal de Noailles, first established the reputation of Linnæus in France; not so much possibly for the sake of his system, as his discoveries, his commodious nomenclature, and his clear principles of discrimination. When Le Monnier botanized in Chili, in the company of the astronomers with whom he was associated, he soon found, like Dr Garden in South Carolina, that the classification of Tournefort was no key to the treasury of a new world. He however made his remarks and collections, and studied them subsequently under the auspices of a more comprehensive guide. The Marechal de Noailles, a great cultivator of exotic trees and shrubs, corresponded with the Swedish naturalist, and endeavoured to recommend him to the notice of the lovers of plants in France. Meantime Gerard and Gouan in the south, both introduced themselves to the illustrious Swede, and promulgated his principles and discoveries, though only the latter adopted his classification. Villars we have already noticed as the author of a Linnæan *Histoire des Plantes de Dauphiné*. He died lately, professor of botany at Strasburg, where he succeeded the very able and philosophical Hermann, one of the truest Linnæans, who had imbibed all the technical style of the Swedish school, as well as its accuracy of discrimination. We may now safely announce Hermann as the real author, in conjunction perhaps with Baron Born, of that ingenious but bitter satire the *monachologia*, in which the several *species* of monks are affectingly discriminated, and their manners detailed, like the animals in the Linnæan *Systema Naturæ*. This ludicrous performance has long since appeared in a not very exact English translation, and was rendered into French by the late M. Broussonet. As we are led again to name this amiable man, too soon lost to his country, after experiencing every vicissitude of revolutionary peril and alarm, we cannot help distinguishing him as one most zealous in the cultivation and diffusion of Linnæan learning, a taste for which he chiefly imbibed in England. He had no indulgence for those prejudices which cramped the talents of his countrymen, and prevented their deriving knowledge from any quarter where it was to be had. He recommended the younger Linnæus to their personal acquaintance and favour; which service he also rendered, a few years after, to the person who now commemorates his worth, and who will ever remember, with affection and regret, his many virtues, his agreeable converse, and his various and extensive acquirements.

"The intimacy which subsisted between this enthusiastic naturalist and the distinguished botanist l'Heritier, confirmed, if it did not originally implant, in the mind of the latter, that strong bias which he ever showed for the Linnæan principles of botany. According to these his numerous splendid works are composed. He moreover imbibed, if we mistake not, from the same source, a peculiar preference for uncoloured engravings of plants, instead of the coloured ones which had long been in use. It cannot be denied that the merit of these last is very various, and sometimes very small. They do, nevertheless, present to the mind a more ready idea of each species, than a simple engraving can do, nor is the latter less liable to incorrectness. When plates are taken from the delineations of such exquisite artists as l'Heritier employed, they have a good chance of excellence; but the engravings of Cavanilles, done after miserable drawings, though they deceive the eye by their neat finishing, are really less exact than many a rude outline. Coloured plates, if executed with the uniformity and scientific exactness of Mr Sowerby's, or the characteristic effect of Jacquin's, speak to the eye more readily than most engravings. The art of printing in colours, practised formerly in England with small success, was revived at Paris by Bulliard, and is carried to the highest perfection in the recent publications of Redouté and Ventenat, which leave hardly any thing to be wished for, with respect to beauty or exactness. Many of the works of l'Heritier have remained imperfect, in consequence of the political convulsions of his country and his own premature death. The learned and worthy Desfontaines, who travelled in Barbary, has been more fortunate in the completion of his labours. His elegant *Flora Atlantica*, in 2 vols. 4to, with finely engraved uncoloured plates, is classed and modelled on the plan of the Linnæan school. Such also is the plan of the works of that distinguished botanist Labillardière, who, besides his account of New Holland plants, has published five elegant *decades* of new species from Syria. That scientific horticulturist M. Thouin, likewise a most excellent botanist, though he has scarcely written on the subject, is a correct pupil of the Swedish school. His general spirit of liberal communication, and his personal attachment to the younger Linnæus, led him to enrich the herbarium of the latter with the choicest specimens of Commerson's great collection, destined otherwise to have remained in almost entire oblivion. A singular fate has attended the discoveries of most of the French voyagers, such as Commerson, Sonnerat, and Dombey, that, from one cause or other, they have scarcely seen the light. So also it has happened to those of Tournefort, Sarrazin, Plumier, and others, whose acquisitions have long slept in the Parisian museums. Happily there seems to have arisen of late a commendable desire to render them useful by publication, and thus many fine plants, known merely by the slight and unscientific appellations of Tournefort, and therefore never adopted by Linnæus, have recently been clearly defined, or elegantly delineated. The journeys of Olivier and Michaux towards the east have enriched the Paris gardens, and been the means of restoring several lost Tournefortian plants. We believe however that the English nurseries have proved the most fertile source of augmentation to the French collections, as appears by the pages of all the recent descriptive writers in France.

"We dare not presume to arrange the indefatigable and very original botanist Lamarck among the Linnæan botanists of his country, but we beg leave to mention him here, as one who has thought for himself, and whose works are the better for that reason. His severe and often petulant criticisms of the Swedish teacher, made him appear more hostile than he really was, to the principles of

Taxonomy.

that great man. Being engaged in the botanical department of the *Encyclopédie Méthodique*, he was obliged to conform to an alphabetical arrangement; but he surely might have chosen the scientific generic names for that purpose, instead of barbarous or vernacular ones, which, to foreigners, would have made all the difference, between a commodious and an unintelligible disposition of his work. In the detail of his performance, he has great merit, both with respect to clearing up obscure species, or describing new ones; and he had the advantage of access, on many occasions, to Commerson's collection. Lamarck's *Flore Française* is arranged after a new analytical method of his own. This book however is valuable, independent of its system, as an assemblage of practical knowledge and observation. We have only to regret a wanton and inconvenient change of names, which too often occurs, and which is not always for the better; witness *Cheiranthus hortensis*, instead of the long established *incanus* of Linnæus; *Melampyrum violaceum*, which is not correct, for *nemorosum*, which is strictly so, and which preserves an analogy with the rest of the species.

"We shall now undertake the consideration of the principles that have been suggested, and the attempts that have been made, respecting a

NATURAL CLASSIFICATION OF PLANTS.

Sexual system.

"The sexual system of Linnæus lays no claim to the merit of being a natural arrangement. Its sole aim is to assist us in determining any described plant by analytical examination. The principles on which it is founded are the number, situation, proportion, or connection, of the stamens and pistils, or organs of impregnation. These principles are taken absolutely, with the sole exception of their not being permitted to divide the genera, that is, to place some species of a genus in one part of the system, and others in another, though such may differ in the number, situation, proportion, or connection of their stamens or pistils; those characters being possibly artificial, while the genera are supposed, or intended, according to a fundamental law independent of all systems, to be natural assemblages of species. We need not here explain the mode in which Linnæus has provided against any inconvenience in practice, resulting from such anomalies of nature herself.

"But though this popular system of Linnæus does not profess to be a natural method of classification it is in many points incidentally so, several of its classes or orders whose characters are founded in situation, proportion, or connection, being more or less perfectly natural assemblages; nor can it be denied that, on the whole, it usually brings together as many groups of natural genera, as occur in most systems that have been promulgated. This fact would be more evident, if the various editors of the system, those who have added new genera to the original ones of Linnæus, or, in general, those who have any way applied his method to practice, had properly understood it. They would then have perceived that its author had always natural affinities in view; his aim, however incompletely fulfilled, according to our advanced knowledge, having constantly been, to place genera together in natural affinity or progression, as far as their relationship could be discerned. At the same time he uses an analytical method, at the head of each class in his *Systema Vegetabilium*, in which the genera are disposed according to their technical characters. Murray, in compiling the fourteenth edition of that work, has been inadvertent respecting this essential part of its plan. Indeed it is probable that he was not competent to judge of the affinities of the new genera, introduced from the *Supplementum*, or from the communication of Jacquin, Thunberg, &c. Yet

surely he might have perceived the affinity of *Banksia* to *Protea*, rather than to *Ludwigia* or *Oldenlandia*; and indeed Linnæus himself ought to have discovered the relationship of the latter to *Hedyotis*, if he did not detect their identity, instead of inserting it between two such strict allies of each other as *Ludwigia* and *Ammannia*. To pursue these remarks would be endless. It is hardly necessary to indicate the natural classes or orders of the Linnæan system, such as the *Tetradynamia*, *Didynamia*, *Diadelphia*, *Syngenesia*; the *Triandria Digynia*, *Gynandria Diandria*, &c. Except the first-mentioned class, which, if *Cleome* be removed, is strictly natural and entire, the others are liable to much criticism. We are almost disposed to allow, what we know not that any one has yet observed, that the system in question is the more faulty in theory, for these classes being so natural as they are. Each order of the *Didynamia* presents itself as a natural order, though the character of that class, derived from the proportion of the stamens, serves to exclude several genera of each order, and to send them far back into the second class. If all ideas of natural affinity be discarded from our minds, there is no harm whatever in this; but if the *Didynamia* claims any credit, as a class founded in nature, the above anomaly is a defect. So, still more, under the same point of view, is the *Diadelphia*, or at least its principal order *Decandria*, liable to exception. This order consists entirely of the very natural family of *Papilionaceæ*. They are characterized as having the ten stamens in two sets. Now it happens that there are many papilionaceous genera, indeed a great number of such have been discovered since Linnæus wrote, whose ten stamens are all perfectly distinct. These therefore are necessarily referred to the class *Decandria*, and they come not altogether amiss there, because they meet in that class some concomitant genera, which though, like them, leguminous, are less exactly, or scarcely at all, papilionaceous. But the greatest complaint lies against some genera of the *Diadelphia Decandria*, for having the stamens all really combined into one set, so as in truth to answer to the technical character of the preceding class *Monadelphia*. There is mostly indeed some indication of a disunion upward, where they, more or less perfectly, form two sets; and some of them are so nearly diadelphous, that their complete union at the bottom may easily be overlooked; others, however, have only a fissure along the upper side of their common tube, without any traces of a separate stamen or stamens. The papilionaceous character of the *corolla* therefore, in such cases, is made to overrule that of the particular mode of union among the stamens, and is in itself so clear, as seldom to be attended with any difficulty; but the incorrectness of principle in the system, in the point before us, as being neither professedly natural, nor exactly artificial, cannot be concealed. Part of the objections, to which the sexual system was originally liable, have been obviated. We mean what concerns the last class but one, *Polygamia*. Dr Forster observed, in his voyage round the world, that this class was subject to great exception, on account of the trees of tropical climates, so many of which are constantly or occasionally polygamous; that is, each individual frequently bears some imperfect flowers, male or female, along with its perfect or united ones. Such a circumstance reduces any genus to the class *Polygamia*; and on this principle Mr Hudson, thinking perhaps that he made a great improvement, removed our *Ilex Aquifolium*, or Holly, thither, though *Ilex* is well placed by Linnæus in the fourth class. The author of the present essay has ventured to propose a scheme, which is adopted in his *Flora Britannica*, for getting clear of this difficulty. He considers as polygamous such genera only as, besides having that charac-

Taxonomy.

ter in their organs of impregnation, have a difference of structure in the other parts of their two kinds of flowers. Thus *Atriplex* has, in its perfect flowers, a regular spreading calyx, in five equal segments; in the attendant female ones a compressed one, of two leaves, subsequently much enlarged.

"The genera thus circumstanced are so very few, as far as we have discovered, that possibly the class might, but for the uniformity of the system, be abolished. We cannot indeed tell what future discoveries may be made; and its character, on the above foundation, is sufficiently clear and permanent; for flowers of an essentially different configuration can hardly vary into each other. The orders of the last class of the Linnæan system, *Cryptogamia*, are natural, and preserved, all nearly the same, by every systematic projector. The original appendix to this system, the *Palmeæ*, would be a great blemish therein, as an artificial arrangement; for such an arrangement ought to be so formed as to admit every thing, on some principle or other. But this stumbling-block is now removed. The palm tribe were placed thus by themselves, merely till their fructification should be sufficiently known. Now they are found to agree well with some of the established classes and orders, where they meet with several of their natural allies.

"Whatever advantages might accrue to the practical study of botany, from the convenience and facility of his artificial system, Linnæus was from the beginning intent on the discovery of a more philosophical arrangement of plants, or, in other words, the classification of nature. This appears from the 77th aphorism of the very first edition of his *Fundamenta Botanica*, published in 1736, where he mentions his design of attempting to trace out fragments of a natural method. In the corresponding section of his *Philosophia Botanica*, he, fifteen years afterwards, performed his promise; and the same *Fragmenta*, as he modestly called them, were subjoined to the sixth edition of his *Genera Plantarum*, the last that ever came from his own hands. The interleaved copies of these works, with his manuscript notes, evince how assiduously and constantly he laboured at this subject, as long as he lived. He was accustomed to deliver a particular course of lectures upon it, from time to time, to a small and select number of pupils, who were for this purpose domesticated under his roof. What this great botanist has himself given to the world, on the subject under consideration, is indeed nothing more than a skeleton of a system, consisting of mere names or titles of natural orders, amounting in his *Philosophia* to sixty-seven, besides an appendix of doubtful genera; and that number is, in the *Genera Plantarum*, reduced to fifty-eight.

"Under the title of each order, the genera which compose it are ranged according to the author's ideas of their relationship to each other, as appears by some of his manuscript corrections; and some of the orders are subdivided into sections, or parcels of genera more akin to each other than to the rest. He ingeniously avowed, at all times, his inability to define his orders by characters. He conceived that they were more or less connected with each other by several points of affinity, so as to form a map rather than a series. The experienced botanist, who peruses the above-mentioned *Fragmenta*, will in most

cases readily imbibe the ideas of their author, as to the respective affinities of the genera. In some few instances, as the *Dumosæ*, where he avows his own doubts, and the *Holeraceæ*, where he is unusually paradoxical, it is more difficult to trace the chain of his ideas. Such, however, was all the assistance he thought himself competent to afford. His distinguished pupils, Fabricius and Giseke, fortunately took notes of his lectures on natural orders; and by the care of the latter, to whom Fabricius communicated what he had likewise preserved, their joint acquisitions have been given to the public, in an octavo volume, at Hamburg, in 1792. Nor was this done without the permission of their venerable teacher, who told Giseke by word of mouth, when they took leave of each other, that 'as he loved him, he had laboured with pleasure in his service;' adding, that 'Giseke was at liberty to publish, whenever he pleased, any thing that he had retained from his own instructions.'

"Linnæus, according to a conversation with Giseke, recorded in the preface of the volume edited by the latter, declined to the last any attempt to define in words the characters of his orders. His reason for this appears in his *Classes Plantarum*, where he justly remarks, that no certain principles, or key, for any such definition can be proposed, till all the orders, and consequently all the plants, in the world are known. He has, however, so far expressed his opinion, in the work last quoted, as to point out the situation of the seed itself, with respect to other parts, and the situation and direction of its vegetating point, or *corculum*, as most likely to lead to a scheme of natural classification. Hence the system of Cæsalpinus stood very high in his estimation. He also, in the conversation above mentioned, divides his own orders into three sections, or classes, *Monocotyledones*, comprising the first ten orders, with the 15th; *Dicotyledones* (with two or more cotyledons), the 11th to the 54th order inclusive, except the 15th; and *Acotyledones*, order 55th to 58th, with a hint that the last, or *Fungi*, ought perhaps to be altogether excluded. This distribution of plants, by the number or the absence of the cotyledons, or lobes of the seed, is the great hinge of all the professedly natural modes of arrangement that have been attempted."

"Linnæus did not consider it as absolute, for he told Giseke that he knowingly admitted into his eleventh order some plants that are monocotyledonous, with others that are dicotyledonous. The reason of this was the only secret he kept from his pupil; nor could the latter ever dive into it, though he afterwards endeavoured to learn it from the younger Linnæus, who knew nothing, neither did he, as Giseke says, much care about the matter."¹

The want of any avowed principle of distinction precludes almost all criticism of these orders of Linnæus as a natural system. They cannot be applied to practice, and might in the present day be passed over in silence. As, however, a very few, and amongst others the late Sir J. E. Smith, considered them as even of more importance than those of Jussieu, an opinion in which we cannot coincide, we shall trace very shortly their names, but omit entirely the notes that usually accompany them, as unphilosophical, and tending but little to benefit the reader.

¹ "Nymphaea appears to be the great secret, which the worthy professor told his pupil, that he, or some other person, might chance to find out in ten, twenty, or fifty years, and would then perceive that Linnæus himself had been aware of it. Accordingly Gærtner and Jussieu have made the same discovery, or rather, fallen into the same mistake, describing *Nymphaea* as monocotyledonous, and *Cyamus*, Sm. *Exot. Bot.* v. i. 59 (their *Nelumbo* or *Nelumbium*), as in some measure dicotyledonous. The excellent De Candolle, in the *Bulletin des Sciences*, No. lvii. published in 1802, has first rightly considered both as dicotyledonous, and akin to the *Papaveraceæ* of Jussieu, the Linnæan *Rhæadææ*."

Taxonomy.

Exposition of the Linnæan natural orders.

I.—*Monocotyledones.*

1. *Palmae*. 2. *Piperitæ*, the flowers of which are crowded into a close spike, including *Arum*. 3. *Calamariæ*, or grass-like plants, not true grasses, as *Carex*, *Typha*, &c. 4. *Gramina*, or the true grasses. 5. *Tripetaloideæ*, in which there were three petals (Linn.), as *Juncus* and *Alisma*. 6. *Ensatae*, where the leaves are ensiform, and the corolla (Linn.) monopetalous. 7. *Orchideæ*, with fleshy roots, and the flowers either furnished with a spur or of a singular construction; the filaments and style are united, and the ovarium inferior. 8. *Scitamineæ*, with herbaceous stems, very broad leaves, a triangular ovarium beneath a liliaceous corolla. 9. *Spathaceæ* are those lilies which have the flowers issuing from a large spathe. 10. *Coronariæ*, or lilies without a spathe, but with a corolla of six petals. 11. *Sarmentaceæ*, with weak stems and liliaceous flowers.

II.—*Dicotyledones.*

12. *Holeraceæ*, "plants tender or brittle in the mouth, and easy of digestion;" the flowers of no beauty. 13. *Succulentæ*, with very thick fleshy leaves. 14. *Gruinales*, having a pentapetalous corolla, several pistils, and a long pointed capsule, as *Geranium*. 15. *Inundatæ*, which grow in or under water, with flowers of no beauty. 16. *Calycifloræ*: here there is only a calyx, on which the stamina are inserted; but the genera put into this were afterwards referred elsewhere by Linnæus. 17. *Calycanthemæ*, where the calyx is seated on the germen or ovarium, and the flowers are beautiful. 18. *Bicornes*, having the anthers provided with two long straight points or horns, as *Erica*, and several others having no real affinity. 19. *Hesperides*, with evergreen leaves, fragrant flowers, and numerous stamens. 20. *Rotaceæ*, having a rotate corolla. 21. *Preciæ*, with handsome early spring flowers, as the primrose. 22. *Caryophylleæ*, or those with a caryophyllaceous corolla. 24. *Trihilatæ*, having a style with three stigmas, and winged or inflated capsules, as *Melia*, *Malpighia*, and *Acer*: 25. *Corydalis*, flowers with a spur, or of a singular form, as in *Epimedium* and *Pinguicula*. 25. *Putamineæ*, bearing fruit in a hard shell, as *Capparis*, and others not allied to each other. 26. *Multisiliquæ*, with a fruit of many siliquæ, as *Trollius*. 27. *Rheadæ*, with a caducous calyx, and a capsule or siliqua. 28. *Luridæ*, corresponding to the *Solanaceæ* of Jussieu. 29. *Campanaceæ*, with bell-shaped flowers, but otherwise an unnatural assemblage. 30. *Contortæ*, with a twisted corolla, as *Nerium* and *Vinca*. 31. *Vepreculæ*, having a monophyllous calyx, coloured like a corolla. 32. *Papilionaceæ*, with papilionaceous flowers. 33. *Lomentaceæ*, with a legume or lomentum, but not a papilionaceous flower. 34. *Cucurbitaceæ*, as *Cucumis* and *Pasiflora*. 35. *Senticosæ*, comprehending many of the *Rosaceæ*. 36. *Pomaceæ*, as *Amygdalus* and *Pyrus*. 37. *Columniferæ*, in which the stamens, as in *Malva*, unite and form a long tube. 38. *Tricocceæ*, with a trilocular capsule, as *Euphorbia*. 39. *Siliquosæ*, corresponding to *Tetradynamia* in the artificial system. 40. *Personatæ*, the same as *Didynamia angiospermia*. 41. *Asperifoliæ*, having "four naked seeds" (Linn.), a monopetalous corolla, five stamens, one style, and rough leaves. 42. *Verticillatæ*, those with labiate or ringent flowers, including some of *Diandria*, and all *Didynamia gymnospermia*. 43. *Dumosæ*, shrubby plants, with a stem furnished with a soft pith: flowers small, the petals of four or five segments, as *Sambucus*, *Rhamnus*, &c. 44. *Separiæ*, shrubs, usually with a tubular corolla, and very few stamens, as *Ligustrum*. 45. *Umbellatæ*, bearing an umbel of flowers, a pentapetalous corolla, five stamens, two styles, and "two naked seeds." 46. *Hederaceæ*, with a quinquefid corolla, five or ten stamens, a baccate fruit, and flowers in a corymb; *Hedera* and *Vitis* were here associated.

47. *Stellatæ*, with a quadrifid corolla, four stamens, and two "naked seeds." 48. *Aggregatæ*, resembling the compound flowers, but with the anthers free. 49. *Compositæ*, or the compound flowers. 50. *Amentaceæ*, with the fruit in a catkin. 51. *Coniferæ*, bearing a strobilus or cone. 52. *Coadunatæ*, which have several berries or fruits united into one, as *Annona*. 53. *Scabridæ*, having rough leaves, and flowers of no attraction, as *Urtica*, *Ficus*, &c. 54. *Miscellaneæ*, or those not referable to the preceding.

III.—*Acotyledones.*55. *Filices*. 56. *Musci*. 57. *Algæ*. 58. *Fungi*.

It will readily appear that many of these are very artificial, and some of the conjunctions quite improper; but, upon the whole, they exhibit a great resemblance in their external appearance, which Linnæus himself could not define in words.

We shall now advert to the French school of Botany; French school. and "here the learned and truly estimable Bernard de Jussieu, the contemporary of Linnæus in the earlier part of his career, first claims our notice. This great practical botanist, too diffident of his own knowledge, extensive as it was, to be over-anxious to stand forth as a teacher, did not promulgate any scheme of natural arrangement till the year 1759, when the royal botanic garden at Trianon was submitted to his direction. His system was published by his nephew in 1789, at the head of his own work, of which it makes the basis. It appears in the form of a simple list of genera, under the name of each order, without any definition, just like the *Fragmenta* of Linnæus, at the end of his *Genera Plantarum*.

"In 1763 a very active and zealous systematic, M. Adanson, made himself known to the world, by the publication of his *Familles des Plantes*. In this learned and ingenious, though whimsical and pedantic work, the great task of defining natural orders by technical characters is first attempted. His affected orthography and arbitrary nomenclature render it scarcely possible, without disgust, to trace his ideas; which, however, when developed, prove less original than they at first appear. His work is written avowedly to supersede the labours of Linnæus, against whom, after courting his correspondence, he took some personal displeasure; and yet many of his leading characters are borrowed from the sexual system. The discriminative marks of his fifty-eight families are taken from the following sources: leaves, sex of the flowers, situation of the flowers with respect to the germen, form and situation of the corolla, stamens, germens, and seeds. Every family is divided into several sections, under each of which the genera are, in like manner, synoptically arranged, and discriminated by their leaves, inflorescence, calyx, corolla, stamens, pistil, fruit, and seeds. In the detail of his system, Adanson labours to overset the principle, so much insisted on by Linnæus and his school, and to which the great names of Conrad Gesner, and Cæsalpinus, are chiefly indebted for their botanical fame, that the genera of plants are to be characterized by the parts of fructification alone. The experienced botanist knows that this is often but a dispute of words; Linnæus having, in arranging the unbelliferous plants, resorted to the inflorescence, under the denomination of a receptacle; see his 45th natural order. But it appears to us that the characters deduced from thence are in themselves faulty, being often uncertain, and not seldom unnatural; and that the plants in question may be better discriminated by their flowers and seeds. Adanson however prefers the inflorescence, even in the *Verticillatæ* of Linnæus; for no reason, that we can discover, but because Linnæus has so much better defined the genera of those plants by the *calyx* and *corol-*

la. It were a needless and ungrateful task to carp at the mistakes of this or any writer on natural classification, with regard to the places allotted for difficult genera, because the human intellect must fault in unravelling the intricate mysteries of Nature. But surely, when *Plantago* is placed with *Buddleia* in one section of the *Jasminææ*, and *Diapensia* with *Callicarpa* in another; when the most natural genus of *Lavandula* is divided and widely separated; when *Cassythia* is ranged with *Statice*, *Eriocaulon*, and the *Proteaceæ*, in one place; *Geoffræa* with *Melia*, *Rhus*, *Sapindus*, and *Ruta*, in another; we may be allowed to wonder, and to doubt whether we are contemplating a natural or an artificial system. It does not appear that Adanson made many proselytes. He haunted the botanical societies of Paris in our time, without associating with any; nor was his extensive knowledge turned to much practical account. Linnæus has made but one slight remark, that we can find, in his own copy of the *Familles des Plantes*, nor could he study deeply what was undoubtedly very difficult for him to read. He certainly never noticed Adanson's attacks, unless the satirical sketch of the *Botanophili*, at the end of his *Regnum Vegetabile*, (see the beginning of *Syst. Veg.* ed. 14), be partly aimed at this author. To apply the whole of it to him would be unjust, though much is very characteristic.

cademy
Sciences.

"The study of Botany had never been entirely neglected in France since the days of Tournefort; because one department in the Academy of Sciences was allotted to that and other branches of natural history; and the seats in the academy being pensioned places under government, there was something to be got by an apparent attention to such pursuits. Buffon and his pupils engrossed zoology. Botany was allowed to exist, so far as not to interfere with his honours; but nothing of foreign origin, and above all, nothing Linnæan, dared to lift up its head. Something of true science, and practical knowledge, did nevertheless imperceptibly work its way. Le Monnier, and the Marechal de Noailles, corresponded, as we have already said, with Linnæus, and acquired plants from England, of which they dared to speak, and to write, by his names. A most able and scientific botanist and cultivator, Thouin, was established in the Jardin du Roi, who studied the Linnæan system, and even ventured, though secretly, to communicate new plants to the younger Linnæus when at Paris. Cels, an excellent horticulturist, was unshackled by academic trammels. L'Heritier, Broussonet, and others, came forward. An original letter of Rousseau, the idol of the day, in which he paid the most flattering homage to botany and to Linnæus, was published in the *Journal de Paris*, and had a wonderful effect on the public mind, and on the conversation of literary circles. In short, a Linnæan party had been, for some time, gaining ground; and every thing was done by party at Paris. The old French school was roused from its slumbers. Of the family of the Jussieus, one individual remained, who, though he venerated the names and the pursuits of his uncles, had never devoted himself to their studies any further than to sit in their professorial chair. He possessed, however, an inherent taste for botany; he had leisure, opulence, and eminent talents; and though his religious principles, and his rather strict devotional habits, might interfere, which they still do, with his credit in certain philosophical circles, and his predilection for animal magnetism might exclude him from the Royal Society of London, yet he has risen above all such obstacles, to the summit of botanical fame and authority in his own country; and his name stands conspicuous, as the leading teacher of a na-

tural classification of plants. The most indefatigable study for about five years, and the constant assistance and encouragement of numerous pupils and correspondents, enabled Professor Antoine Laurent de Jussieu to publish, in 1789, his *Genera Plantarum secundum ordines naturales disposita*. This octavo volume was received by acclamation throughout Europe, and hailed as the most learned botanical work that had appeared since the *Species Plantarum* of Linnæus."

"The whole preface of Jussieu is a concise and learned review of the physiology and distinctions of plants, more particularly explaining the progress of the author's ideas and principles of botanical classification. The main end of the whole book, besides defining the characters of all known genera, is to dispose them in a natural series, in various classes and orders, whose technical distinctions are throughout attempted to be fixed and contrasted."¹

The first in England who wrote a systematic work according to the natural method of Jussieu, was Mr Brown, the most able botanist of this or any former age; and no one has done so much, in any country, to throw light on its intricacies. Salisbury, Hooker, Don, and Lindley, have respectively contributed their share; but we regret to say, that hitherto, in Britain, from the simplicity of the Linnæan system for enabling one to obtain the name of a plant, and from the want of good elementary works in our language to guide the student, the natural classification, except among a few of the principal botanists, has been very little attended to. Another great desideratum has been a *Species Plantarum*, or work containing all the known species, arranged in this way: but this is at present attempted by Professor De Candolle of Geneva, and when his *Prodromus Systematis Regni Vegetabilis* is completed, we do not hesitate to state that, notwithstanding a multitude of errors, it will prove to be one of the most valuable works ever presented to the public, and will tend more to establish the method than all the books previously written on the subject.

"The advantages of such a system," says Mr Lindley, "in applying botany to useful purposes, are immense, especially to medical men, with whose profession the science has always been identified. A knowledge of the properties of one plant is a guide to the practitioner, which enables him to substitute some other with confidence which is naturally allied to it; and physicians on foreign stations may direct their inquiries, not empirically, but upon fixed principles, into the qualities of the medicinal plants which nature has provided in every region for the alleviation of the maladies peculiar to it. To horticulturists it is not less important: the propagation or cultivation of one plant is usually applicable to all its kindred; the habits of one species in an order will often be those of the rest; many a gardener might have escaped the pain of a poisoned limb, had he been acquainted with the laws of affinity; and finally, the phenomena of grafting, that curious operation, which is one of the grand features of distinction between the animal and vegetable kingdoms, and the success of which is wholly controlled by ties of blood, can only be understood by the student of the natural system."

The natural method having in view not the mere naming of plants, which can of itself be interesting to only a limited number of individuals, but the classifying them according to the groups which nature herself forms, or rather, as nature forms only species, according to the resemblance that one tribe of vegetables bears to another, we must, consequently, conform as much as possible to

Taxonomy.

her laws; and to know these we must first obtain a precise idea of the organization of plants, studying minutely all their parts, and the functions of each. This we have already attempted to elucidate under the head of Glossology. We now come to examine into the relative importance of these organs, in order that we may derive from them a classification according to nature.

When different seeds taken from the same plant are made to germinate, we have individuals not entirely agreeing in the shape of the leaves, or the height of the stem; from which we may infer that characters derived from these are of the least importance; and consequently, when we form species, we must use such with great caution. But when we rise a step higher, and group species into genera, we find so great a variety in both the stem and leaves, that we are forced to look for characters elsewhere, and thus resort to the different parts of the flower; and all genera are therefore founded on a consideration of these. When, however, we come to examine a genus by itself, we shall find that perhaps none of these parts are sufficiently constant, some species differing from others in the number or shape of the sepals, or petals, or stamens, or pistilla, so that we are obliged to call into action not any particular one, but a combination of the whole. While doing this, it cannot escape our notice that the more external portions, as the calyx, exhibiting more of the foliaceous origin, are less constant than the petals; and these again less so than the stamens; but the stamens and pistils having least of the structure of the original leaf, are the most uniform; and hence Linnæus, influenced principally however by these being the true sexual organs, adopted the stamina and pistils as the basis of his system. Now we have already said that, in many natural genera, plants differ from one another only specifically, although there happen to be a difference in the number of parts of the reproductive organs. Number, then, not being at all times sufficient to constitute a genus, can still less be relied on for a higher division. The structure must thus be considered; and this we not only find common to the species of a genus, but even often to different genera so allied in aspect that at first we might consider them all as one great genus; and such a great genus being in fact an order, we are led, while defining it, to place considerable dependence on the structure of the anthers, but more especially on the fruit, the ultimate metamorphosis of the primary leaf. But on comparing together two or more orders otherwise very closely allied, we often perceive very different structures of the fruit; so that, in search of something more fixed, we are compelled to dip still deeper into the economy of the plant, and examine the seed. Here, indeed, we find a great diversity in the external form; but on scrutinizing the interior, particularly the embryo, or the very rudiment of the plant, we find only *two* modifications; and each of these, after having opened different seeds, we perceive to be constant to a very great class of plants united together, whether by the structure of the fruit, the number of stamens, or by the flower, or by the anatomy of the stems, or by the leaves. These modifications of the embryo, resting on there being one or two cotyledons, must thus form the groundwork of a natural method: it was already foreseen by Linnæus, but was demonstrated by Jussieu. We only here allude to those plants in which a seed and embryo exists; for the very principle we have laid down implies its existence. A primary division, then, pointed out by nature, is therefore obviously into those with flowers and those that have none, or into those which have seeds and an embryo, and such as have neither true seeds nor an embryo.

Primary divisions.

First, then, we have a division into Exembryonate and Embryonate vegetables; and, secondly, the Embryonate

divides into those with one and those with two cotyledons, which was no sooner fixed than many corresponding differences of structure became perceptible. Thus *Monocotyledones* show a radicle that projects the root through a covering. The divisions of the flower are ternary; the leaves are curvinerved, primarily alternate or spiral, but indicating a disposition to become opposite at the summit of the plant; the stem is cylindrical, and increasing in diameter from within by an expansion of the vascular fibre. The *Dicotyledones*, on the contrary, have opposite cotyledons; the radicle of the embryo becomes a root by mere development; the division of the flower is usually quinary; the leaves are angulinnerved, and primarily opposite or verticillate, with a tendency to become alternate towards the inflorescence; the stem is conical, with a bark, and both increasing by concentric layers, the stem from without, the bark from within.

Having thus attained primary divisions with important Second and constant characters, we are next to proceed to subdivision. We divide these into orders; but in doing this we must observe, that though it be quite possible to group genera into orders, and to place these orders in one of the great divisions above given, it is almost impracticable to place them satisfactorily one after the other so as to constitute a book. Each order is not allied merely to the one that precedes and that which follows it, but approaches more or less to several others. In arranging them, then, in a linear series, all that we can attempt is to place those next each other that have common characters of most value or of greatest number; and as the value and number of these are added to or diminished by the discovery of new plants and modern analyses, we must expect daily changes to take place. In this consists the difficulty of the natural method, when compared with a purely artificial one; but these difficulties are from time to time smoothed down, so that ultimately it will be viewed as the only useful one, while the artificial system will be entirely neglected, except by those whose desires extend no farther than to make out the name of a vegetable.

Jussieu considered the whole floral envelopes of the *Monocotyledones* as a calyx, whether coloured or green; and observing that a portion of the *Dicotyledones* were also destitute of a corolla, he laid hold of this to divide them into two parts, as had been already done by Tournefort: at the same time he separated those with a corolla into one and many-petaled. These sections, however, being artificial, cannot be entirely depended on in practice, many species belonging to a polypetalous order having the corolla abortive; while again, as in the *Pentapetaloidæ* of Ray, several of those also with a polypetalous corolla have the unguis or claws united, so that it is in reality a monopetalous one, although arranged with the other. Linnæus had already introduced the insertion of the stamens to distinguish his class *Icosandria* from *Polyandria*; and this bringing together plants tolerably nearly allied in other respects, Jussieu extended the idea, and having observed that stamens not hypogynous were either perigynous or epigynous, he made use of these three characters to subdivide both the *Monocotyledones* and each of the sections of the *Dicotyledonous* plants. Only one of these he found necessary further to divide, in order to separate *Syngenesia* of Linnæus from those approximated to them in several other characters, but of a different habit or appearance, and had here recourse to the union or separation of the anthers. These ultimate subdivisions he termed classes, and to the end of them he appended one consisting of such *Dicotyledones* as had the flowers unisexual, and were therefore principally contained in the 21st, 22d, and 23d classes of Linnæus. We have already seen, in treating of the parts of a flower, that the stamens and corolla have

Taxonomy.

always the same insertion, and that when a corolla is gamopetalous, or, in common language, monopetalous, the cause that unites the petals often also makes part of the filaments adhere to it. Among the monopetalous plants, then, to prevent confusion, Jussieu, instead of saying that the stamens were hypogynous or perigynous, speaks of the insertion of the corolla; and, with these remarks, we may now present the fifteen classes of Jussieu.

I.—Cotyledons none.

Cl. 1. *Acotyledones*.

II.—Monocotyledones.

2. *Monohypogynæ*, stamens hypogynous.
3. *Monoperigynæ*, stamens perigynous.
4. *Monoepigynæ*, stamens epigynous.

III.—Dicotyledones.

§ 1. Apetalæ.

5. *Epistamineæ*, stamens epigynous.
6. *Peristamineæ*, stamens perigynous.
7. *Hypostamineæ*, stamens hypogynous.

§ 2. Monopetalæ.

8. *Hypocorollæ*, corolla hypogynous.
9. *Pericorollæ*, corolla perigynous.
10. *Epicorollæ synantheræ*, corolla epigynous, anthers united.
11. *Epicorollæ corisantheræ*, corolla epigynous, anthers free.

§ 3. Polypetalæ.

12. *Epipetalæ*, stamens epigynous.
13. *Peripetalæ*, stamens perigynous.
14. *Hypopetalæ*, stamens hypogynous.

§ 4. Diclinae.

15. *Diclinae*, flowers unisexual, or without a perianth.

Such was the groundwork of the system which, though in some things artificial, was instantly perceived to bear the palm from all that preceded it; and this, without any alteration, is still adhered to in France by many of the most eminent botanists. Jussieu originally prefixed no names to his classes, and the want of this was much objected to. Those which we have given have been lately proposed by Antoine L. de Jussieu in the *Dictionnaire des Sciences Naturelles*; and, although not entirely according to the principles of the Greek language, may be adopted as extremely useful, each being so framed as to suggest the structure of the class. Thus the commencement *Mono* indicates the Monocotyledones. *Epistamina*, &c. having no allusion to a corolla, suggests its absence. *Hypocorollæ*, and the others, allude to the corolla being of one piece, and not of distinct petals, which last is pointed out by names *Epipetalæ*, &c. The other parts of the names, epi, peri, and hypo, need no explanation.

While engaged in the study of plants alone, it is obviously of little consequence whether we begin, as Jussieu did, by the Acotyledones, or by the Dicotyledones; but if we view botany as a science that treats of only one of the great kingdoms of nature, and wish to introduce it into a *Systema Naturæ*, we must bring those portions of each most closely together which are most nearly linked. So that if we commence by Zoology, we must first describe the Mammalia, and end by those of a simpler structure, and then take up the most allied of the Acotyledones, and follow the steps of Jussieu. But if we describe vegetables

in the first place, we must begin with the Dicotyledones, and finish with the Acotyledones. When, however, a *Systema Vegetabilium* is contemplated without reference to animals, it may perhaps smooth the way to the student if it commences by those more obvious, and, though of more complex formation, yet more simple to be comprehended. On this account De Candolle has reversed the arrangement of Jussieu.

We have said that in some respects the system of Jussieu is artificial, and therefore his orders need not necessarily follow each other precisely as he has left them. De Candolle accordingly divides the Dicotyledones into *Thalamifloræ*, or those whose petals are distinct and hypogynous; *Calycifloræ*, having the petals either distinct or united, but always inserted on the calyx; *Corollifloræ*, with the petals united, and hypogynous, and bearing the stamens; and *Monochlamydeæ*, with a simple perianth or perigonium. Moreover, he derives his characters for all these united, not from the cotyledons, but from the structure of the stem, and terms them Exogenæ; and in a similar way he calls Monocotyledones by the name of Endogenæ, with this alteration, that he supposes the ferns and allied plants, which in another part we have termed Ductulosæ, to have the same structure of a stem as the Monocotyledones, and therefore divides the Endogenæ into *Phanerogamæ* and *Cryptogamæ*. The other Acotyledones, named by him *Cellulares*, from their entire homogeneity of cellular tissue, conclude the system. Although he has given us an arranged catalogue of the orders in his *Theorie Elementaire*,¹ which, however, he has considerably altered in his *Prodromus*, now publishing, yet he has scarcely exhibited any subdivisions of his principal groups. It may be, however, useful to present the following sketch of his, contrasted as much as possible with that of Jussieu.

A. Exogenæ (<i>De Candolle</i>). Dicotyledones (<i>Jussieu</i>).	
I. Thalamifloræ.....	1. Hypopetalæ.
II. Calycifloræ.....	2. Peripetalæ.
	3. Epipetalæ.
	4. Epicorollæ corisantheræ.
	5. Epicorollæ synantheræ.
III. Corollifloræ.....	6. Pericorollæ.
	7. Hypocorollæ.
IV. Monochlamydeæ.....	8. Hypostamineæ.
	9. Peristamineæ.
	10. Epistamineæ.
	11. Diclinae.
B. Endogenæ.	
V. Phanerogamæ.....	12. Monoepigynæ.
	13. Monoperigynæ.
	14. Monohypogynæ.
VI. Cryptogamæ.....	15. Acotyledones.
C. Cellulares.	
VII. Cellulares.....	

From the above it will be perceived, although some sneer at the natural system, because they do not understand it, and assert that every one has a method of his own, and quote De Candolle's as extremely distinct from that of Jussieu, that it is in fact founded on, and not differing in any essential point from, that of the Parisian botanist.

Mr Lindley, in his *Introduction to the Natural System of Botany*, has discarded nearly all these subdivisions as empirical, and substituted in their place one derived from the ovulum, being protected by a pericarp, or exposed without any covering to the influence of the pollen. This last is of very great importance, and is worthy of being

¹ Second Edition, p. 213. (1819).

Taxonomy.

adopted; but any one who has glanced at his volume must have soon felt the great want of more minute divisions than he has adopted, however artificial they might be; nor do we think that he has compensated for the deficiency by a more judicious disposition of the orders.

We ourselves shall follow pretty closely that given by De Candolle, because, from his publishing a work containing all the known species arranged according to it, it is almost the only one that can be of use to a student of species. But while we do so, we shall subdivide his groups in the manner recommended by Jussieu; not that they are to be implicitly trusted, but that they may in some measure assist the reader while referring to the orders.

Characters of the orders.

We must now advert to the orders themselves; and these being great natural genera, in order to obtain characters for them, we must have an intimate knowledge of the structure of the organs of the component genera and species, so as to select such as are common to all, and of the greatest importance. Botanists having seen that the embryo gave most fixed characters for a general division, have looked to it also, and to the structure of the seed, as of great influence in limiting each order individually. This view was altogether omitted by Jussieu at the time the *Genera Plantarum* was given to the world, but is now frequently adopted as a criterion, when other and more easily examined points fail. The structure of the fruit we have already said to be useful for defining genera, and consequently must not be passed over while circumscribing an order; nor must the position of the seed be omitted. As to the carpel, the stigma affords few good marks; but the ovarium must be strictly attended to, especially as a contrast to the mature fruit, many plants having two or three cells in the ovarium, and but one by abortion in the fruit. Thus the structure of the ovary is in several of greater importance than that of the fruit. The apocarpous or syncarpous nature of the ovarium, upon which we have already dwelt, must be noticed. The position of the placenta and the ovules has likewise been esteemed of great value. The stamina, whether viewed relatively to their insertion, their adherence, proportional size, or number, and particularly the structure of the anther, and even the pollen, all indicate greater or less affinities in other points.

The floral envelopes must be considered in all their bearings, and even the inflorescence must not be neglected. The relative position, also, of one part of a flower to another, whether the number be symmetrical or complete, enables us often to clear up many difficulties. But it is not one of these alone in which we are to confide, but in a combination of them: two orders, differing solely by one character, being too closely allied, had better be united; a *clavis analytica*, therefore, such as has been given by Mr. Lindley in his introduction, can convey to us almost no idea of the orders, and, besides, has the disadvantage of not exhibiting the anomalies that so frequently occur.

Having exhausted all the parts of the flower, we may then turn our attention to the leaves; and here we may take advantage of a character that is intimately connected with the habit or external aspect of the order, and is consequently truly natural; we allude to the leaves being opposite or alternate, and with or without stipules. The presence or absence of pellucid dots, exhibiting a peculiar organization in the plant, must be carefully observed. Compound or simple leaves are often of use to enable us to refer a plant to a particular order. The mere shape of leaves is too variable, but the venation, or disposition of the nerves, upon which the shape of the leaf depends, as

the fruit does upon the ovary, although hitherto not much attended to, seems in many cases of considerable importance. As to the stem, the external variations, as erect or climbing, square or round, sometimes aid us, but in most orders afford us no assistance. The root has been rarely found of any avail.

We have again and again stated that we are not to take the characters of orders from any one organ individually, but from several. Each order may thus be expected to possess some points in common with several other orders, and by the number of these, and their value, as found from experience, we are able to trace the affinity between any one, and those that ought to be arranged in its vicinity. When several very important points are nearly the same in four or five different orders, though distinct in many others, a greater approximation is visible between themselves, than any of them exhibits to other orders: this has induced Mr. Brown to propose to erect orders into classes of a different kind from those of Jussieu; and he has happily succeeded in accomplishing this in several instances. Very few such classes or aggregate orders have, however, yet been formed, and therefore we shall not enter into their consideration farther than merely remark that this is, at present, greatly to be desired in the natural method, and that, when it shall be accomplished, and the whole distributed among a few great compound orders, we may be able to do away entirely with even the slight remains we now must admit into it, of an artificial or empirical arrangement.

It is now time that we proceed to enumerate and lay down the characters of the orders themselves. Jussieu constituted a hundred, and subjoined a list of many genera, either so little known, or so ill defined, that he could not refer them. By degrees, however, as light was thrown upon them, some were entered into known orders, while others exhibited the necessity of constructing additional ones. In his *Théorie Élémentaire*, in 1819, De Candolle enumerates 161 orders, but has since admitted many new ones in his *Prodromus*. Richard, in 1828, describes 162, but omits a few which he considered not well understood. Rudolphi, in 1830, gives 276; and about the same time Mr. Lindley has 272. Both Rudolphi and Lindley, however, carry the system of subdivision perhaps to excess; but as our object is here to give a view of the science at the present day, we shall admit almost all of them, arranging, however, the minor ones under a general head, to which, for conciseness, we shall give no character, and which may be viewed, if one pleases, as a class. To as short a definition of the orders as possible we shall annex a few remarks, which we trust may render this department more interesting.

ARRANGEMENT AND CHARACTERS OF THE NATURAL ORDERS.

I. VASCULARES.

A. EXOGENÆ. DE CAND. (DICOTYLEDONES. JUSS.)

DIV. I.—*Dichlamydeæ Thalamifloræ*. D. C.

(1. Hypopetalæ.¹ JUSS.)

Order 1. *Ranunculaceæ*. JUSS.

Sub-order 1. *Ranunculineæ*. Sepals distinct, various in number, from three to fifteen, but usually five, deciduous: estivation generally imbricated, sometimes valvate.

¹ In the divisions with several petals, the petals are sometimes, though rarely, abortive; it is then difficult to decide whether the plant comes here or belongs to the monochlamydeæ.

range-
ment and
characters.

Corolla of 5-15 petals¹ (or absent by abortion), distinct. Stamens distinct, indefinite in number: anthers adnate, extrorse. Ovaria seated on the torus, indefinite, or rarely (by abortion) solitary, usually apocarpous, and rarely somewhat syncarpous: style one to each ovary, simple: ovules solitary? or several, adhering to the inner edge. Carpels various, either achenia which are sometimes baccate, or follicular with 1-2 valves. Albumen between fleshy and horny. Embryo minute, inclosed in the albumen near its base.—Herbaceous, suffrutescent, or rarely shrubby plants. Leaves alternate, or sometimes opposite, simple but variously divided: petiole dilated and forming a sheath half-clasping the stem. Hairs, when present, simple.—Ex. *Clematis*, *Anemone*, *Ranunculus*, *Helleborus*.

Suborder 2. *Cimicifugeæ*. Sepals 4-5, distinct, deciduous: estivation imbricated. Petals 4-5, distinct. Stamens distinct, indefinite: anthers adnate, introrse. Ovaria seated on the torus, apocarpous, indefinite or rarely solitary: styles simple: ovules 2-3, or more, in each ovary, adhering to the inner margin. Carpels follicular or baccate. Seeds several or solitary, exarillate. Albumen between fleshy and horny. Embryo minute, inclosed at the base of the albumen.—Herbaceous or suffrutescent. Leaves simple, divided, alternate. Flowers racemose.—Ex. *Cimicifuga*, *Actæa*, *Zanthorrhiza*.

Suborder 3. *Pæoniæ*. Sepals five, foliaceous, persistent, unequal: estivation imbricated. Petals five, sometimes 6-10 by culture, distinct, somewhat equal, destitute of claws: estivation imbricated. Stamens very numerous: anthers adnate, introrse. Torus large, fleshy, annular, surrounding the base of the ovary. Ovaria 2-5, apocarpous: style none: stigmas sessile, thick, of two lamellæ: ovules numerous. Carpels follicular, tipped with the persistent stigmas, opening above by a longitudinal suture. Seeds several, exarillate: umbilicus prominent. Embryo minute, straight, inclosed at the base of the fleshy albumen.—Herbaceous or shrubby plants. Leaves alternate, divided. Flowers terminal, solitary, large.—Ex. *Pæonia*.

The first suborder is usually divided into four, *Clematideæ*, *Anemoneæ*, *Ranunculeæ*, and *Helleborineæ*, distinguished by a combination of the estivation, and position of the seed; but as it appears probable that in the ovary there is always at least two ovules, so the position of the seed, whether erect or pendulous, must depend entirely on which of the ovules, the upper or lower, becomes abortive. In general terms the *Ranunculaceæ* may be known from other *Hypopetalæ* by having adnate anthers that dehisce longitudinally, by a fruit of several distinct simple carpels, by a horny albumen, exarillate seeds, and exstipulate sheathing leaves.—Acridity, causticity, and poison, are the general characters of this order.

Order 2. *Dilleniaceæ*. D. C.

Sepals five, persistent. Corolla of five petals, deciduous, in a single row. Stamens numerous; filaments dilated either at the base or apex. Anthers adnate, introrse, bursting longitudinally. Ovaria definite, more or less distinct, with a terminal style and simple stigma; ovules ascending. Fruit of 2-5 distinct unilocular carpels, or of a similar number cohering together: the carpels are either capsular or baccate, and pointed by the style. Seeds several in each carpel, or only two or one by abortion, surrounded by a pulpy arillus. Testa hard. Embryo straight, minute, at the base of a fleshy albumen.—Leaves alternate, or rarely opposite, without stipules.—Ex. *Delima*, *Dillenia*.

Known by the longitudinally dehiscent anthers, distinct simple carpels, arillate seeds, fleshy albumen, and exstipulate leaves. In some genera, however, there is but one carpel, and in a few others they partially cohere. They are trees or shrubs, or even undershrubs.—They are generally astringent; most have the leaves covered with asperities, which are sometimes so hard as to permit of their use for polishing.

Order 3. *Magnoliaceæ*. Juss.

Suborder 1. *Wintereæ*. R. Br. Sepals 2-6, deciduous or persistent. Petals 2-30 (when more than five, in several rows). Stamens indefinite, distinct: anthers adnate, dehiscent longitudinally. Ovaria definite in one verticil, one-celled, ovules suspended. Stigmas sessile. Fruit of distinct carpels. Embryo very small, straight in the base of a fleshy albumen.—Leaves alternate, transparently dotted, coriaceous, with convolute deciduous stipules.—Ex. *Illicium*, *Wintera*.

Suborder 2. *Magnoliæ*. Juss. Sepals 3-6, deciduous. Petals 3-27, in several rows. Stamens indefinite, distinct; anthers adnate, long, bursting longitudinally. Ovaries numerous in several rows, one-celled: ovules ascending or suspended: styles short. Fruit of numerous carpels, which are either dehiscent or indehiscent, distinct or partially connate, sometimes samaroid. Embryo minute at the base of a fleshy albumen.—Leaves alternate, not dotted, coriaceous, with deciduous convolute stipules.—Ex. *Magnolia*, *Liriodendron*.

These two suborders, scarcely distinguishable from each other but by their leaves, may be characterized by their longitudinally dehiscent anthers, apocarpous ovaria, and stipulate leaves.—The first tribe is aromatic and stimulant; and the *Drymis Winteri* yields the winter's bark, well known for its resemblance to cinnamon. The second is not at all aromatic; but the flowers, which are large, are often strongly odoriferous; they have a bitter tonic taste, but the bark does not seem to possess either tannin or gallic acid. The bark of the tulip-tree has been said to equal Peruvian bark.

Order 4. *Anonaceæ*. Juss.

Sepals 3-4, persistent, often partially cohering. Petals 6, in two rows, coriaceous; estivation valvular. Stamens indefinite (very rarely definite): anthers adnate, extrorse, with a large connectivum. Ovaries usually numerous, separate or sometimes cohering, rarely definite: ovules solitary or several, erect or ascending. Fruit of a number of succulent or dry carpella, that are one or many-seeded, and distinct, or concrete into a fleshy mass. Testa of the seed brittle. Embryo minute at the base of a hard fleshy ruminated albumen.—Trees or shrubs. Leaves alternate, simple, without stipules.—Ex. *Anona*, *Guatteria*.

The apocarpous ovaria, ruminated albumen, and exstipulate leaves, are the general characteristics of this order.—Almost all possess a powerful aromatic taste and smell; in some the fruit contains much sugary mucilage, and is succulent and eatable; of this kind are the custard-apples, and the celebrated Cherimolia of Peru.

Order 5. *Menispermaceæ*. Juss.

Flowers usually unisexual, and very small. Sepals and petals having the same appearance, in one or several rows; three or four in each row, deciduous. Stamens monadelphous or occasionally free, sometimes opposite to the petals and equal to them in number, sometimes three or four times as many: anthers adnate, extrorse. Ovaria usually numerous, free or slightly united by their inner margin, unilocular. Drupes baccate, one-seeded, oblique,

Arrange-
ment and
Characters.

¹ For the sake of brevity, we shall seldom state, under the respective orders, that the stamens or petals are hypogynous or perigynous, trusting that this may be inferred from the divisions *Hypopetalæ*, *Peripetalæ*, and the like, which we have already explained. When, however, there is any discrepancy, we shall notice it.

Arrangement and Characters.

lunate, and compressed, or rarely a multilocular berry, with the cells many-seeded. Embryo curved, radicle superior. Albumen none, or in small quantity and fleshy.—Climbing shrubs, with alternate leaves and very minute flowers.—Ex. *Menispermum*, *Cissampelos*.

The stamens opposite the petals, apocarpous ovaria, minute unisexual flowers, and twining shrubby stems, point out this order.—The root of several species is bitter and tonic, and of some the seeds are narcotic. A few have been used in intermittent fevers. The columbo root, so esteemed for its tonic, antiseptic, and astringent qualities, belongs to the genus *Menispermum*.

Order 6. *Berberideæ*. VENT.

Sepals 3-4-6, deciduous, in a double row, accompanied externally with petaloid scales. Petals equal to the sepals in number and opposite to them, or twice as many; often furnished in the inside with an appendage at the base. Stamens equal in number to the petals and opposite to them: anthers bilocular, the cells opening elastically with a valve from the bottom to the top. Ovary solitary, unilocular, containing 2-12 ovules, which are erect, or attached laterally to the inner margin, and forming there one or two rows: style sometimes lateral, short: stigma orbicular. Fruit baccate or capsular, indehiscent. Albumen fleshy or horny. Embryo straight, in the axis of the albumen: radicle pointing to the hilum: cotyledons flat.—Leaves alternate, without stipules.—Ex. *Berberis*, *Leontice*.

The single simple carpel, stamens opposite to the petals, and the anthers opening by valves, will readily distinguish this from the other Hypopetalæ. This kind of anther is of rare occurrence, but equally exists in the Laurineæ, Hamamelideæ, and Atherospermeæ. There are no stipules, the spines being the true leaves, of which the parenchyma has disappeared, and the nerves become indurated: what are commonly called leaves are those formed by the development of the leaf-buds. All are articulated with the petiole, and hence the leaves are in reality compound, although apparently simple. The stamens of many exhibit great irritability.—The berries of some species of *Berberis* are acid and astringent, and form with sugar an agreeable preserve.

Order 7. *Podophyllaceæ*. D. C.

Sepals 3-4. Petals in two or three rows, each equal in number to the sepals. Stamens 12-18, arranged in two, three, or more rows; filaments filiform: anthers terminal, introrse, opening by a double longitudinal line. Torus small. Ovary solitary: style one, short: stigma somewhat peltate. Fruit succulent or a capsule, one-celled. Seeds indefinite, attached to a lateral placenta. Embryo small, at the base of a fleshy albumen.—Plants herbaceous. Leaves broad and lobed, without stipules.—Ex. *Podophyllum*, *Jeffersonia*.

This order is allied to the Berberideæ, to the last tribe of Ranunculaceæ, and to Papaveraceæ, with which some botanists unite it.—The roots possess purgative properties.

Order 8. *Hydropeltideæ*. D. C.

Sepals 3-4, alternate with the sepals. Stamens two or more times the number of the petals: anthers linear, introrse, continuous with the filament. Torus inconspicuous. Ovaries two or more, stigmas simple. Fruit indehiscent, tipped with the indurated styles, containing one or two pendulous seeds. Embryo inclosed in the endosperm, is fungilliform, and seated at the base of a firm somewhat fleshy perisperm.—Aquatic plants, with floating leaves.—Ex. *Hydropeltis*, *Cabomba*.

The situation of this order was formerly involved in some doubt, as Richard, mistaking the endosperm, insisted that the embryo was fungilliform, or shaped like a little mushroom or a small nail, and perfectly monocotyledo-

nous. De Candolle unites it to Podophyllaceæ as a section. In some points the above, and the only two genera, approach very closely to the Nymphaeaceæ, to which Brown unites them; and *Hydropeltis* is somewhat related to *Caltha* among the Ranunculaceæ.

Order 9. *Nymphaeaceæ*. SALISB.

Suborder 1. *Nelumboneæ*. D. C. Sepals 4-5. Petals numerous in many rows. Stamens indefinite in several rows: filaments petaloid: anthers adnate, introrse, opening by a double longitudinal cleft. Torus fleshy, elevated, very large, inclosing in hollows of its substance the numerous separate ovaria, which have a simple style and stigma. Nuts inserted, but loose, in the hollows of the torus, 1-2-seeded. Perisperm 0: endosperm conspicuous. Embryo large, with two fleshy cotyledons.—Aquatic herbs with peltate leaves. Ex. *Nelumbium*.

Suborder 2. *Nymphaeæ*. D. C. Sepals and petals numerous, passing into each other. Stamens indefinite, in several rows: filaments petaloid: anthers adnate, introrse, opening by two longitudinal clefts. Torus large, fleshy, surrounding more or less completely the ovaria, styles, and stigmas. Ovaria apocarpous, attached to the inside of the bottle-shaped, indehiscent torus, on the top of which are the radiate stigmas. Seeds very numerous in each carpel, attached to spongy placenta that form the false dissepi-ments of the fruit. Endosperm fleshy, and, with the inclosed embryo, seated on the outside of the base of the farinaceous perisperm: cotyledons foliaceous.—Aquatic herbs, with peltate or cordate fleshy leaves.—Ex. *Nymphaea*, *Nuphar*.

We cannot see that these tribes can be separated, and we almost coincide with Brown, that the Hydropeltideæ may be added to this order. We have already (p. 49) sufficiently explained the structure of the fruit of *Nuphar*.—Their medical properties are not well understood, but they are reputed to be narcotic and sedative.

Order 10. *Sarraceniaceæ*. TURP.

Sepals five, persistent: estivation imbricated. Petals five. Stamens indefinite: anthers adnate, bilocular, bursting internally and longitudinally. Ovary five-celled: style single: stigma persistent, much dilated, peltate, with five angles. Capsule quinque-locular, valves five, loculicide. Seeds very numerous, small: placenta large at the inner angle of the cells. Albumen copious. Embryo cylindrical, lying near the base of the seed, with the radicle pointing to the hilum.—Herbaceous bog plants. Leaves radical, with a hollow petiole, at the apex of which is the lamina covering the orifice of the petiole like a lid. Scapes one-flowered.—Ex. *Sarracenia*.

On account of the stigma this family has been usually placed near Papaveraceæ. Mr Lindley suggests its affinity to *Dionæa*, wherever that be placed.

Order 11. *Papaveraceæ*. JUSS.

Sepals two, deciduous. Petals four cruciate (or a multiple of four), regular, rarely wanting. Stamens eight, or some multiple of four, usually indefinite, inserted in four parcels, one of which adheres to the base of each petal: anthers bilocular, erect. Ovary solitary: style short or none: stigmas alternate with the placenta, two or many, in which case they are stellate on the flat apex of the ovary. Fruit one-celled, either siliquiform with two, or capsular with several, parietal placenta. Seeds numerous. Albumen between fleshy and oily, at the base of which is a minute straight embryo, with plano-convex cotyledons.—Plants herbaceous or shrubby, with a milky juicc. Leaves alternate, divided. Peduncles long, one-flowered.—Ex. *Papaver*, *Eschscholtzia* (Plate CXXII.)

This order approaches to the Podophylleæ on the one hand, and to the Crucifereæ on the other. In *Eschscholtzia* the apex of the peduncle dilates, and bears on it the

organs of reproduction; the calyx in it is apparently of one piece, and separates like an operculum from the very base. —Narcotic properties prevail in this family, except in the seed, which is oily. The narcotic principle of opium is an alkaline substance called Morphia.

Order 12. *Fumariaceæ*. D. C.

Sepals two, deciduous. Petals four, cruciate, one or both of the two outer saccate at the base, the two inner callous at the apex, where they cohere and inclose the anthers and stigma. Stamens six, diadelphous, opposite the outer petals: anthers of the middle stamens of each parcel two-celled, of the outer ones one-celled. Ovary one-celled: style filiform, stigma with two or more points. Fruit a one-seeded utricle, or a two-valved, two-seeded, indehiscent capsule, or a two-valved, polyspermous stigma. Seeds with an arillus attached to narrow parietal placenta. Albumen fleshy. Embryo nearly straight, minute, eccentric. —Herbaceous plants, with a watery juice. Leaves alternate, multifid. —Ex. *Fumaria*, *Dielytra*.

Nearly allied to the last order, but distinct in the definite diadelphous stamens and irregular corolla. The central anthers being alone bilocular, suggests that two of the others make but one, or that there is in reality here but four stamens, one before each petal. And even Mr Lindley has demonstrated that the inner petals form a corolla, while the outer ought to be viewed as sepals: the deciduous sepals above described would thus be bracteæ. —The *Fumariaceæ* are slightly bitter, and act as diaphoretics and aperients.

Order 13. *Cruciferae*. Juss.

Sepals four; two corresponding to the two stigmas are anterior and posterior, and narrower than the others; two are lateral, or corresponding to the valves, broader, concave at the base, gibbous or spurred. Corolla cruciform. Petals four, alternate with the sepals, nearly equal, deciduous. Stamens six; the two opposite the lateral sepals are solitary, shorter, and occasionally toothed; four in pairs opposite the anterior and posterior sepals, longer, generally free, sometimes connate, or furnished with a tooth on the inside: anthers bilocular, introrse. Torus with several green glands between the petals and the stamens, and ovary. Ovary syncarpous, bilocular. Placenta parietal, usually meeting in the middle, and forming a spurious dissepiment. Stigmas two, opposite the placenta, or anterior and posterior. Fruit a silique or silicula, rarely one-celled and indehiscent, usually spuriously bilocular, and dehiscing by two valves separating from the placenta; one or many-seeded. Seeds campulitropous, pendulous, attached in a single row by a funiculus to each side of the placenta. Albumen none. Embryo with the radicle folded up on the cotyledons, which are next the placenta. —Herbaceous plants, or very seldom suffruticose. Leaves alternate. —Ex. *Draba*, *Lepidium*, *Sinapis*, *Bunias*.

This order having six tetradynamous stamens, can scarcely be confounded with any other. We have already explained (p. 49) the structure of the fruit according as Mr Lindley and we understand it. Mr Brown gives a different explanation, upon which we have not room to enter. —The general character of the *Cruciferae* is to possess antiscorbutic and stimulant qualities, with an acrid flavour. They contain much azote, and have therefore, when in a putrescent state, been occasionally used in the manufacture of Prussian blue, when the horns and hoofs of cattle could not be had in sufficient quantity.

Order 14. *Capparideæ*. Juss.

Sepals four. Petals four, cruciate, usually unguiculate and unequal. Stamens four, six, or indefinite, but in general some high multiple of four. Torus hemispherical or elongated, often bearing glands. Ovary stalked: style

one, filiform, or sometimes none. Fruit unilocular, siliqueform, or fleshy and indehiscent, rarely one-seeded, usually with two polyspermous placenta at the margin of the valves or carpels. Seeds generally reniform, with a thickened tegmen. Albumen none. Embryo incurved: cotyledons foliaceous, somewhat flat. —Leaves alternate, stalked, undivided, or palmate. Stipules none, or spinouscent. —Ex. *Cleome*, *Capparis*.

Allied to *Cruciferae*: indeed Linnæus arranged some of the genera in *Tetradynamia*. The stipitate ovary, and the fruit, indicates some affinity to *Passifloreæ*. —The properties are not very dissimilar from those of the last order. The root of *Cleome dodecandra* is used as a vermifuge.

Order 15. *Resedaceæ*. D. C.

Sepals 4-6, persistent. Petals 4-6, alternate with the sepals, unequal; the upper ones with a scale-like claw and palmatipartite limb, the lateral ones 2-3-lobed, the lower smaller and entire. Stamens 10-24: filaments more or less and variously united: anthers bilocular, erect, opening longitudinally. Torus very short, or resembling a stipes, bearing under the stamens an obtuse nectariferous scale. Ovaria 3-6, each with one style, free, or united into a syncarpous ovary. Fruit of 3-6 few-seeded follicles, dehiscing internally; or a capsule, unilocular, polyspermous, 3-6-valved, indehiscent except at the apex. Placenta parietal in the middle of the valves or follicles. Seeds somewhat pendulous, the testa crustaceous. Albumen very thin and fleshy. Embryo curved: radicle superior: cotyledons fleshy. —Herbaceous plants, with alternate leaves; stipules none, or represented by glands. —Ex. *Reseda*.

Most botanists agree in bringing this family near to the *Capparideæ*, except Mr Lindley, who conceives it to be more nearly allied to *Euphorbiaceæ* and *Datisceæ*. —*Reseda luteola* yields a yellow dye, and *R. odorata* or *Mignonette* is well known for its fragrant flowers.

Order 16. *Flacourtiaceæ*. Rich.

Sepals 4-7, cohering slightly at the base. Petals equal in number to, and alternate with, the sepals, sometimes wanting. Stamens equal in number to the petals or some multiple of them, occasionally changed into nectariferous scales. Ovary roundish, sessile or slightly stalked: style none, or filiform: stigmas several, more or less distinct. Fruit unilocular, containing a thin pulp, either fleshy and indehiscent, or capsular with 4-5 valves. Placenta parietal, branching all over the inner surface of the valves. Seeds few, thick, often enveloped in a pellicle formed by the withered pulp. Albumen fleshy, somewhat oily. Embryo straight in the axis, with the radicle turned towards the hilum: cotyledons flat, foliaceous. —Leaves alternate, simple, without stipules. Flowers sometimes unisexual. —Ex. *Patrisia*, *Flacourtia*, *Kiggelaria*, *Erythrospermum*.

The peculiar placenta of this order occurs in no other of the Dicotyledones. In some things they resemble the *Capparideæ*. —The fruit of several species of *Flacourtia* is eaten: that of *Hydnocarpus* is used in Ceylon for poisoning fish, which at the same time renders them unfit for food.

Order 17. *Bixineæ*. KUNTH.

Sepals 4-7, distinct, or cohering at the base: estivation imbricated. Petals five, resembling the sepals, or none. Stamens indefinite, free, inserted on the discoid torus: anthers bilocular. Ovary sessile, one-celled: ovules attached to 2-7, narrow, parietal placenta: style single, or 2-4 cleft. Fruit capsular or baccate, one-celled, many seeded: placenta in the middle of the valves. Seeds enveloped in pulp. Albumen fleshy, or very thin, including the embryo, which is slightly curved: radicle pointing to the hilum: cotyledons foliaceous. —Leaves alternate, simple, with deciduous stipules. —Ex. *Prockia*.

From the last family this is chiefly to be distinguished

Arrange-
ment and
Characters.

by the narrow and not ramified placenta: still Richard unites them; and we would have also done this, were it not that Mr Lindley places upwards of 120 orders between them, and does not even notice their affinity. Don suggests that the name Prockiaceæ ought rather to be adopted, for that *Bixa* is nearly related to *Sloanea* and *Ablania*, among the Tiliaceæ. This order also bears some relation to the Cistineæ and Homalineæ.—The pulp surrounding the seeds of *Bixa* (or the Arnotto) is purgative and stomachic.

Order 18. *Cistineæ*. Juss.

Sepals five, persistent, unequal; the three inner with a twisted estivation. Petals five, very caducous; estivation corrugated, and twisted in an opposite direction to that of the sepals. Stamens indefinite, free: anthers adnate. Ovarium syncarpous, one or many-celled: style single: stigma simple. Fruit capsular, 3-5-10-valved, one-celled, with parietal placenta in the middle of the valves, or imperfectly 5-10-celled, with dissepiments proceeding from the middle of the valves, and meeting in the axis of the fruit. Seeds indefinite. Embryo either spiral or curved, in the midst of a mealy albumen: radicle at the opposite extremity from the hilum.—Shrubs or herbaceous plants. Leaves usually opposite below, alternate above, with or without stipules.—Ex. *Cistus*, *Helianthemum*.

The inverted embryo and loculicidal dehiscence are what must be chiefly relied on in defining the limits of this order.—The balsamic substance called Labdanum, which must not be confounded, as some ignorant people have done, with Laudanum, is obtained from *Cistus Creticus*.

Order 19. *Violariææ*. D. C.

Sepals five, persistent; estivation imbricated. Petals five, usually withering, generally unequal; estivation obliquely convolute. Stamens five, alternate with the petals, or occasionally opposite to them, inserted on the hypogynous disc or torus: anthers bilocular, introrse, closely approximated, or united laterally to each other: filaments dilated, elongated beyond the anthers; two of them, in the irregular flowers, usually with an appendage at the base. Ovary one-celled, with many (rarely one) ovules: style single, usually declinate, with an oblique cucullate stigma. Capsule three-valved, loculicide, or bearing the placenta on the middle of the valves. Embryo straight, erect, in the axis of a fleshy albumen.—Leaves alternate, rarely opposite, with persistent stipules and an involute vernation.—Ex. *Viola* (Plate CXVII.), *Alsodeia*.

The irregular flowered genera are easily distinguished from those of other orders; but those with regular flowers, constituting the section Alsodineæ, are so with more difficulty. Of the latter, *Pentaloba* was said to have five placenta, but that seems contradicted by Brown. The placenta are opposite to the three outer sepals.—The roots of all the species are more or less emetic, and some of them are substituted for Ipecacuanha.

Order 20. *Droseraceæ*. D. C.

Suborder 1. *Droserææ*. Sepals five, persistent, equal; estivation imbricated. Petals five. Stamens free, withering, five and alternate with the petals, or ten: anthers bilocular, bursting longitudinally. Ovary one: styles 3-5, slightly connected at the base or distinct, bifid or branched. Capsule 3-5-valved, loculicide, one-celled, or spuriously three-celled, the dissepiments being formed by the placentas meeting in the axis. Seeds without an arillus; testa sometimes loose, and distinct from the tegmen. Embryo straight, erect, in the axis of a fleshy or cartilaginous albumen.—Leaves alternate, furnished (except in *Aldrovanda*), with glandular hairs, with a circinate vernation. Stipules in the form of cilia at the base of the petioles.—Ex. *Drosera*, *Aldrovanda*.

Suborder 2. *Parnassieæ*. Sepals five; estivation imbricated. Petals five, alternate with the sepals. Stamens 10-20, some of them often sterile: anthers bilocular, bursting longitudinally. Ovary solitary, unilocular: style none, and four sessile stigmas opposite the placenta, or one with a lobed stigma. Fruit a capsule, one-celled, 4-5-valved and loculicide; or indehiscent, and then the placenta is only at the base. Seeds numerous. Albumen 0. Embryo erect, or the radicle pointing to the hilum.—Bog plants. Leaves nearly all radical, without glandular hairs.—Ex. *Parnassia*, *Dionæa*.

Some botanists describe the stamens of *Droseraceæ* as perigynous, which, however, we do not think distinctly made out; but were that true, they would approach to the Saxifrageæ. As to our second suborder, *Parnassia* has been referred by Lindley, as was already suggested by Brown, to the Saxifrageæ, but by Don to the Hypericineæ. Richard, again, who affirms it to be a genuine *Droseraceæ*, places *Dionæa* among the Hypericineæ; while Lindley retains it, for the time, among the *Droseraceæ*, but pointing out an affinity with the *Sarraceniaceæ*. But the four stigmas opposite to the placenta in *Parnassia* seem to indicate that these are each composed of two half stigmas belonging to different carpels, and consequently that the styles have a tendency to become united, although bifid in their upper portion, as in *Drosera*. The stigma of *Dionæa* may be similarly explained. The syncarpous ovary is at variance with the Saxifrageæ; and, in the Hypericineæ, the styles alternating with the margins of the carpels, and the sometimes capitate stigmas, demonstrate that the styles are there free and the stigmas undivided. Hence we have brought them under *Droseraceæ*, from which they chiefly differ by their habit and absence of albumen.—The genus *Drosera* is rather acid, slightly acrid, and reputed poisonous to cattle.

Order 21. *Polygaleæ*. Juss.

Sepals five, very irregular, distinct; three exterior, of which one is superior and two inferior; two interior, petaloid, lateral: estivation imbricated. Petals unequal, usually three, of which one is inferior, while the others alternate with the upper and lateral sepals. Sometimes there are five, the two additional ones being minute, and between the lateral and lower sepals: the lower petal (called the *keel*), is sometimes entire, and then naked or crested, or sometimes three-lobed without a crest. Stamens eight, unequal, ascending, combined into a tube, which is split opposite to the upper sepal: anthers one-celled, opening by a terminal pore, or very rarely by a longitudinal cleft. Ovarium bilocular, with placenta in the axis; the cells anterior and posterior, the latter often abortive: ovules one, rarely two, pendulous: style simple, curved: stigma simple. Fruit loculicide, or sometimes indehiscent. Seeds pendulous, with a caruncula next the hilum. Albumen copious, fleshy, rarely reduced to a thin gelatinous plate. Embryo straight, with the radicle next the hilum.—Leaves without stipules.—Ex. *Polygala*, *Securidaca*.

The petal being inferior, and the sepal superior, distinguish this family from the Leguminosæ, to which, in some respects, they bear greater affinity than to any other. *Krameria*, usually referred here, has, we think, been misunderstood, and we therefore exclude it.—Bitterness is the principal property, but the roots of *Polygala Senega* and *sanguinea* are stimulant, diuretic, emetic, purgative, expectorant, sialagogue, sudorific, and emmenagogue.

Order 22. *Tremandreeæ*. R. BROWN.

Sepals 4-5, nearly equal, slightly cohering at the base, deciduous; estivation valvate. Petals 4-5, alternate with the sepals, deciduous; in estivation involute, much larger than the sepals, and including the stamens. Stamens distinct, 8-10, two before each petal: anthers 2-4-celled,

Arrangement and Characters.

opening by a terminal pore. Ovarium bilocular: ovules 1-3 in each cell, pendulous: style one: stigmas 1-2. Capsule two-celled, two-valved, loculicide. Seeds pendulous, with a caruncular appendage at the apex, but with a naked hilum. Embryo cylindrical, straight, in the axis of a fleshy albumen: radicle next the hilum.—Heath-like shrubs, with usually glandular hairs. Leaves alternate or verticillate, without stipules. Pedicels solitary, axillary, one-flowered.—Ex. *Tetralthea*, *Tremandra*.

Perhaps nearest allied to Polygalæ, but differing in several particulars. They are all from New Holland.

Order 23. *Tamariscineæ*. DESV.

Calyx 4-5-partite, persistent: estivation imbricated. Petals 4-5, inserted on the receptacle, marcescent; estivation imbricated. Stamens equal to the petals in number, or twice as many, free or monadelphous. Ovarium one-celled: style short: stigmas three. Capsule three-valved, one-celled, loculicide, polyspermous. Placentæ sometimes only at the base of the capsule. Seeds erect or ascending, comose. Albumen 0. Embryo straight, with the radicle next the hilum.—Shrubs or herbs. Leaves alternate, like small scales.—Ex. *Tamarix*, *Myricaria*.

Placed by De Candolle and most botanists among the orders with perigynous stamens; but Ehrenberg has lately shown that these organs are there hypogynous. To us also they appear hypogynous, and we have therefore inserted this order next the Frankeniaceæ. The insertion of the petals is more difficult to be traced, whether they be like the stamens, as is most probable, or, as some state, inserted into the very base of the calyx.—The bark is slightly bitter and astringent. The ashes of some species contain much sulphate of soda. The manna of Mount Sinai, consisting wholly of mucilaginous sugar, is produced by a variety of *Tamarix Gallica*.

Order 24. *Frankeniaceæ*. ST HIL.

Sepals five, slightly cohering at the base. Petals five, alternate with the sepals. Stamens opposite to the sepals, five, eight, or indefinite: filaments usually very short, free: anthers bilocular, extrorse, bursting longitudinally, or by two terminal pores. Ovarium one-celled, with three parietal placentæ: style slender, simple, or trifid. Capsule one-celled, three-valved, septicide. Seeds numerous, very minute. Embryo straight, cylindrical, in the axis of a fleshy albumen: radicle turned towards the hilum.—Leaves alternate or verticillate, usually furnished with stipules; but which are wanting in *Frankenia*.—Ex. *Frankenia*, *Sauvagesia*.

The flowers are regular, except in *Luxemburgia*. In *Lavradia* there is an internal monopetalous corolla; in *Sauvagesia* an internal pentapetalous one, between which and the true corolla are many capillary or clavate filaments: these accessory parts being abortive stamens. This family is closely allied to the Cistineæ, Violarieæ, and Droseraceæ, from which it differs by the septicidal dehiscence.

Order 25. *Elatineæ*. CAMBESS.

Sepals 3-5, distinct, or slightly connate at the base. Petals alternate with the sepals. Stamens equal in number to, or twice as many as, the petals. Ovarium 3-5-celled: styles 3-5: stigmas capitate. Placentæ in the axis. Capsule 3-5-celled, 3-5-valved, loculicide. Seeds numerous. Albumen 0. Embryo cylindrical: radicle next the hilum.—Annual marsh plants. Leaves opposite, with small inconspicuous stipules.—Ex. *Elatine*, *Bergia*.

The capitate stigmas, want of albumen, and loculicidal dehiscence, have caused this small group to be separated from the Caryophyllæ. The seeds are usually cylindrical and curved; and the embryo has the same shape, and is not straight, as some have described it.

Order 26. *Caryophyllaceæ*. JUSS.

Sub-order 1. *Vivianieæ*. Sepals five, united into a

Arrangement and Characters.

monophyllous, campanulate, 5-toothed calyx, persistent. Petals five, unguiculate, persistent. Stamens ten: filaments filiform: anthers erect, bilocular, bursting longitudinally. Ovarium 3-celled: ovules two in each cell, horizontal, approximated: style short: stigmas three, linear, papillose on the inner surface. Capsule 3-celled, 3-valved, loculicide. Seeds two in each cell, attached closely together to about the middle of the axis, campulitropous. Albumen fleshy, copious. Embryo filiform, curved round the albumen.—Under shrubs. Leaves opposite, tomentose beneath.—Ex. *Viviania*.

Suborder 2. *Caryophylleæ*. Sepals 4-5, distinct or cohering in a tube, persistent. Petals 4-5, unguiculate, sometimes wanting. Stamens usually double the number of the petals, or, if equal, alternate with them. Filaments subulate, sometimes cohering. Anthers erect, bilocular, opening longitudinally. Ovarium one, syncarpous, often stipitate. Stigmas 2-5, sessile, filiform; papillose on their inner surface. Capsule 2-5-valved, one-celled, or imperfectly (rarely completely) 2-5-celled, opening usually by twice as many teeth as stigmas, sometimes by valves. Placenta in the axis of the fruit. Seeds indefinite, or rarely definite, campulitropous. Albumen mealy, round which the embryo is curved.—Leaves opposite and entire, often connate at the base, without stipules.—Ex. *Dianthus*, *Cerastium*.

After Don, we unite *Viviania* (*Macræa*, LINDL., and *Cæsarea*, ST HIL.) to this order; but perhaps its affinity is greater with *Ledocarpum*, which most authors place in the great group of Geraniaceæ. The petals of *Viviania* are scarious. We are very doubtful if any of the true Caryophylleæ have complete dissepiments. *Hymenella* and *Physa* are little known, and most of, if not all, the genus *Mollugo* must be removed, the definite stamens being alternate with the sepals, as in Portulacæ. The number of teeth at the apex of the capsule demonstrate that the dehiscence, if perfect, would have been loculicidal.—A few have sponaceous properties. They are all very insipid.

Order 27. *Malvaceæ*. JUSS.

Sepals five, rarely 3-4, more or less cohering at the base, often bearing an external calyx or involucre: estivation valvate. Petals equal in number to the sepals: estivation twisted. Stamens monadelphous, indefinite, or rarely as few as the petals. Anthers one-celled, reniform, bursting transversely. Ovarium formed by the union of several carpels round a common axis, either distinct or cohering. Styles as many as the carpels, united or free. Fruit capsular or baccate: carpels one or many-seeded, sometimes closely united, sometimes separate or separable. Dehiscence loculicidal or septicidal. Albumen 0, or in very small quantity. Embryo curved: cotyledons twisted and doubled up.—Leaves alternate, stipulate. Hairs stellate.—Ex. *Lavatera*, *Hibiscus*, *Sida*.

The affinity between Malvaceæ and Caryophyllaceæ is very obscure. De Candolle considered the Lineæ as a connecting order; but that differs exceedingly from both in the structure of the seed, and, according to St Hilaire, ought to form a part of the Geraniaceæ.—All abound in mucilage, and are destitute of unwholesome qualities. Cotton is the covering of the seed in the genus *Gossypium*. From the *Althæa officinalis* is prepared, in France, the valuable tracing paper, known by the name of *papier végétale*.

Order 28. *Bombaceæ*. KUNTH.

Calyx gamosepalous, campanulate or cylindrical, truncate or quinque-partite, with a few minute bracteas on the outside. Petals five, regular, or none: estivation twisted. Stamens five, ten, fifteen, or more: filaments cohering at the base into a tube, which is soldered to the tube of the petals, divided above into five parcels, each of

Arrangement and Characters

which bears one or more anthers, intermixed sometimes with barren filaments: anthers one-celled, linear. Ovary of five (rarely ten) carpels, either strictly cohering or partly distinct: styles as many as the carpels, free, or more or less cohering. Placentæ in the axis. Fruit variable, capsular, or indehiscent, usually with five valves and loculicide. Seeds often inclosed in a woolly or pulpy covering; sometimes with a fleshy albumen and flat cotyledons; sometimes exalbuminous with wrinkled or convolute cotyledons.—Leaves alternate, with stipules. Pubescence on the herbaceous parts stellate.—Ex. *Bombax*, *Helicteres*.

These were separated from Malvaceæ by Kunth and De Candolle, but again united by St Hilaire: they chiefly differ by the calyx not being decidedly valvate in estivation, and by the polyadelphous stamens.—Like the Malvaceæ, they are mucilaginous, and possess no deleterious properties. The dried leaves of *Adansonia*, or the Baobab tree, have been used in cases of diarrhœa and fevers; its fruit also is frequently eaten; and the expressed juice mixed with sugar has been valued in putrid fevers. The seeds of some are covered with long hairs, as in the true cotton plant.

Order 29. *Byttneriaceæ*. R. BROWN.

Calyx naked, or with an involucre: sepals five, more or less united at the base: estivation valvate. Petals five or none, often saccate at the base, and variously lengthened at the apex: estivation convolute. Stamens equal to the number of the petals, or some multiple of them, more or less monadelphous, some of them often sterile: anthers bilocular, extrorse. Ovary of five (rarely three) carpels, more or less syncarpous: styles as many as the carpels, free or united: ovules ascending, 2-3 or many in each carpel. Capsule 3-5-celled, 3-5-valved. Seeds with a strophiolate apex, often winged. Albumen oily or fleshy, rarely wanting. Embryo straight: radicle inferior: cotyledons foliaceous, flat and plaited, or rolled round the plumula; or, in the exalbuminous seeds, very thick.—Trees or shrubs. Pubescence often stellate. Leaves alternate, simple, exstipulate.—Ex. *Sterculia*, *Byttneria*, *Lasiopetalum*, *Hermannia*, *Dombeya*, *Wallichia*.

The six genera we have cited as examples have been made the types of as many sections, and even, by some botanists, of as many different orders. As a group, however, on the other hand, they have been united by St Hilaire to the Malvaceæ, although differing in their bilocular anthers. They form the passage to the next order, from which they differ by their monadelphous stamens. In *Sterculia* and *Erythropsis* the carpels are distinct, and in *Waltheria* there is but one, four being abortive.—They abound in mucilage. The Kola of the African travellers is got from the seeds of *Sterculia acuminata*, and Chocolate from those of *Theobroma Cacao*.

Order 30. *Tiliaceæ*. JUSS.

Suborder 1. *Tilia*. Sepals 4-5: estivation valvate, rarely imbricated. Petals 4-5, rarely wanting. Stamens free, usually indefinite: anthers bilocular, dehiscing longitudinally. Torus with 4-5 glands at the base of the petals. Ovary solitary, of 4-10 carpels: style one: stigma with as many lobes as carpels. Fruit dry, multilocular, with several seeds in each cell; or by abortion unilocular and one-seeded. Embryo erect, in the axis of a fleshy albumen: cotyledons flat, foliaceous.—Leaves alternate, stipulate. Petals entire.—Ex. *Tilia*, *Corchorus*.

Suborder 2. *Elæocarpeæ*. JUSS. Sepals 4-5, without an involucre: estivation valvate. Petals 4-5: estivation imbricated. Torus large, discoid, usually with glands. Stamens 15-20: filaments short, free: anthers long, bilocular, opening at the apex by a double fissure. Ovary multilocular: style one: stigmas equal to the number of carpels, sometimes united. Fruit various, indehiscent, dry, drupaceous, or valvular and loculicide, sometimes by

abortion one-celled. Seeds two or more in each cell. Albumen fleshy. Embryo erect: cotyledons flat, foliaceous.—Leaves alternate, sometimes approximated in pairs, with deciduous stipules. Petals lobed or fimbriated, sometimes entire.—Ex. *Elæocarpus*, *Aristotelia*.

The large discoid torus, distinct stamens, and bilocular anthers, serve to distinguish this order from the Malvaceæ and others allied to them; at the same time De Candolle very properly suggests that Malvaceæ, Bombaceæ, Byttneriaceæ, and Tiliaceæ, may all form one group or class, remarkable, as he says, for the valvate estivation of the calyx; for although it be now known that *Sloanea* and *Ablania* have it imbricated, yet these have so much affinity with *Bixa*, that the three may be considered as intermediate between the Bixineæ (or more properly Prockiaceæ) and Tiliaceæ.—The *Tilia* are mucilaginous. The fruit of some is succulent and eatable.

Order 31. *Dipterocarpeæ*. BLUME.

Calyx tubular, five-lobed, unequal, naked, persistent, and afterwards enlarged: estivation imbricated. Petals sessile, slightly connected at the base: estivation twisted. Stamens indefinite: filaments dilated at the base, free or irregularly cohering: anthers erect, bilocular, subulate, opening by terminal fissures. Torus small, not discoid. Ovary with few cells: ovules in pairs, pendulous: style and stigma simple. Fruit coriaceous, one-celled by abortion, three-valved or indehiscent, surrounded by the calyx. Seed solitary. Albumen none. Radicle superior: cotyledons twisted and crumpled, or unequal and obliquely incumbent.—Trees abounding in resin. Leaves alternate: vernation involute. Stipules deciduous, convolute.—Ex. *Dipterocarpus*, *Shorea*.

Allied to *Elæocarpeæ*, and also to the Malvaceæ, and in some few respects to Guttiferæ, but easily distinguished by the enlarged foliaceous unequal segments of the calyx investing the fruit.—The camphor tree of Sumatra belongs to this order. The fruit of the *Vateria indica*, when boiled, yields a kind of tallow.

Order 32. *Chlenaceæ*. THOUARS.

Involucre 1-2-flowered, persistent. Sepals three, small. Petals 5-6, broader and sometimes cohering at the base. Stamens rarely 10, usually indefinite: filaments united at the base into a tube, or adhering to the base of the petals: anthers roundish, syngenesious or free, bilocular. Ovary solitary, trilocular: style one, filiform: stigma trifid. Capsule three-celled, or by abortion one-celled. Placenta central. Seeds solitary or numerous, suspended. Embryo in the axis of a fleshy or horny albumen: cotyledons foliaceous, undulated.—Leaves alternate, with stipules.—Ex. *Sarcolena*, *Leptolæna*.

From this order Hugonia ought certainly to be excluded, it only differing from the Byttneriaceæ (Suborder Dombeyaceæ) by the imbricated, and not valvular, estivation of the calyx. Jussieu, from considering the union of the petals at the base, refers Chlenaceæ to the neighbourhood of the Ebenaceæ. All the species are natives of Madagascar, and very little known.

Order 33. *Ternstræmiaceæ*. MIRB.

Sepals five, concave, coriaceous, deciduous, the innermost often the largest: estivation imbricated. Petals five, often combined at the base, alternate with the sepals. Stamens indefinite: filaments often cohering at the base into one or more parcels, and united to the petals. Ovary plurilocular, usually sessile on a discoid torus: ovules two or more, pendulous at the inner angle of each cell: styles 2-5: stigmas simple. Fruit 2-5-celled, coriaceous and indehiscent, or capsular and opening by valves. Seeds large, few, sometimes arillate. Albumen 0, or in very small quantity. Embryo either straight, or bent, or folded back: radicle next the hilum: cotyledons very large,

Arrangement and Characters

Arrangement and Characters.

sometimes longitudinally plaited, often containing oil.—Leaves alternate, coriaceous, exstipulate, now and then pellucido-punctate.—Ex. *Ternstroemia*, *Gordonia*, *Camellia*.

Cochlospermum has the dissepiments imperfect, and consequently the ovarium spuriously one-celled. In *Camellia*, from the effect of luxuriant cultivation, there are often six or seven petals, styles, and cells to the fruit. This order is allied to the *Aurantiaceæ*, and also to the *Guttiferæ*; but they also osculate with the *Hypericineæ*, *Marcgraaviaceæ*, and *Tiliaceæ*.—The properties of most of the species are little understood. An excellent table oil is obtained from the seeds of *Camellia oleifera*. The tea of commerce is produced by several species of *Thea* and *Camellia*.

Order 34. *Olacineæ*. MIRB.

Calyx small, of one piece, entire, or toothed, often finally becoming large and fleshy: estivation imbricated. Petals 3-6, distinct, or adhering in pairs by the intervention of stamina: estivation valvate. Stamens (fertile) definite, 3-10, alternate with the petals, mixed with others that are sterile and opposite to the petals: filaments compressed: anthers erect, bilocular, bursting longitudinally. Ovarium 1-3-4-celled: ovules 3-4, pendulous from the top of a central placenta: style simple: stigma 3-4-lobed. Fruit drupaceous, indehiscent, often surrounded by the enlarged calyx, one-celled, one-seeded. Seed pendulous. Albumen copious, fleshy. Embryo small, at the base of the albumen: radicle next the hilum.—Leaves simple, alternate, exstipulate, sometimes abortive.—Ex. *Olar*, *Ximenia*.

A very distinct order, although it be somewhat difficult to discover its proper place. Brown supposes the calyx above described to be bracteæ, and the petals a perianth, and consequently it would be placed near the *Santalaceæ*. Jussieu, again, admits the presence of both calyx and corolla, but that the last is monopetalous, and places the order near the *Sapotææ*.—Nothing is known of their medical properties.

Order 35. *Aurantiaceæ*. CORR.

Calyx urceolate or campanulate, short, 3-5-toothed, withering. Petals 3-5, broad at the base, sometimes slightly combined: estivation imbricated. Stamens equal in number to, or a multiple of, the petals: filaments flattened at the base, distinct, monadelphous, or polyadelphous: anthers erect. Torus conspicuous, discoid. Ovarium multilocular: style one: stigma one, somewhat divided, thickish. Fruit a hesperidium. Seeds attached to the axis, solitary or numerous, usually pendulous: raphe and chalaza usually very distinct. Albumen 0. Embryo straight: radicle next the hilum: cotyledons thick, fleshy: plumula conspicuous.—Trees or shrubs, abounding in volatile oil. Leaves alternate, often compound, articulated with a usually winged petiole.—Ex. *Citrus*, *Limonia*.

The oily receptacles dispersed over the whole plant, deciduous and compound leaves (always indicated by the joint connecting them with the petiole) distinguish this family from its allies.—The pulp of the fruit is more or less acid. The oil is volatile, fragrant, bitter, and exciting. The orange, lemon, citron, and lime, belong to this order.

Order 36. *Hypericineæ*. JUSS.

Sepals 4-5, distinct or cohering, unequal, persistent, with glandular dots: estivation imbricate. Petals 4-5, often dotted with black; veins oblique: estivation twisted. Stamens indefinite, polyadelphous (very rarely ten monadelphous): anthers versatile. Ovarium solitary: styles several, rarely connate: stigmas simple, sometimes capitate. Placentæ in the axis. Fruit baccate or capsular, of many cells and valves, septicide. Seeds minute, indefinite, very rarely solitary. Albumen none. Embryo

Arrangement and Characters.

straight: radicle next the hilum, inferior.—Juice resinous. Leaves dotted, usually opposite, and entire. Flowers generally yellow.—Ex. *Hypericum*, *Vismia*.

Allied on the one hand to *Guttiferæ*, and on the other, but more distantly, to *Cistineæ*. The juice of many species is purgative and febrifugal.

Order 37. *Reaumurieæ*. EHRENBERG.

Calyx 5-partite, persistent, surrounded externally with imbricated bracteæ. Petals five. Stamens definite and monadelphous, or indefinite and polyadelphous. Torus with or without glands. Ovarium solitary: styles slender, 2-4-5. Placentæ at the base. Capsule of two, four, or five cells, and as many valves, loculicide. Seeds definite, erect, hairy, large. Embryo straight, in the axis of a farinaceous albumen: radicle next the hilum.—Shrubs. Leaves fleshy, small, alternate, exstipulate. Flowers solitary.—Ex. *Reaumuria*, *Holachna*.

The petals and stamens are hypogynous. *Reaumuria* has peltate anthers, and was formerly placed at the end of the *Ficoideæ*; *Holachna* was the *Tamarix Songarica* of Pallas.—Saline matter exists in great abundance.

Order 38. *Guttiferæ*. JUSS.

Sepals 2-6, usually persistent, round, frequently unequal, and coloured: estivation imbricated. Petals 4-10. Stamens indefinite, or rarely definite, free, or variously united at the base: filaments unequal: anthers adnate, introrse, or extrorse; sometimes very small, sometimes unilocular, and sometimes opening by a pore. Torus fleshy, occasionally five-lobed. Ovarium solitary, one or many-celled: ovules solitary, erect or ascending; or numerous and attached to central placenta: style none, or very short: stigmas peltate or radiate. Fruit capsular, or fleshy, or drupaceous, one or many-celled, one or many-seeded, valvular and septicide, or indehiscent. Seeds definite, in a pulp, apterous, often arillate: testa thin and membranous. Albumen none. Embryo straight: radicle pointing to (or from?) the hilum: cotyledons usually cohering.—Trees or shrubs, sometimes parasitical: juice resinous. Leaves exstipulate, opposite, or rarely alternate, coriaceous, with a strong midrib, and many oblique lateral parallel veins. Flowers articulated with their peduncle.—Ex. *Clusia*, *Calophyllum*.

In *Calophyllum* the petals seem opposite to the sepals, but in the other genera they are alternate. This order approaches most to the *Hypericineæ*, but differs in several particulars: it is also allied to the following family.—A yellow, viscid, acrid, and purgative gum-resinous juice abounds in all. The powerfully drastic and cathartic gamboge is obtained from *Stalagmitis cambogioides*.

Order 39. *Marcgraaviaceæ*. JUSS.

Sepals 2-7, usually coriaceous and persistent: estivation imbricated. Corolla five-petaled, or sometimes monopetalous, calyptriform, entire, or torn at the point. Stamens indefinite, very rarely only five: filaments free, dilated at the base: anthers long, erect, bursting inwards. Ovarium solitary, unilocular: style one or none: stigma lobed or stellate. Placentæ 4-12, parietal, prominent, and forming spurious dissepiments, more or less complete. Fruit coriaceous, indehiscent, or of several valves, separating from below, loculicide. Seeds indefinite, minute, in a pulp. Albumen 0. Embryo straight: radicle next the hilum.—Shrubs. Leaves alternate, simple, entire, almost sessile, and coriaceous.—Ex. *Marcgravia*, *Norantea*.

Some botanists describe the structure of the fruit differently, by supposing the lamellate placenta to be imperfect, but true dissepiments; and this idea is confirmed by the ovules being only attached to the free extremity of this part. But the above is Professor Richard's hypothesis, and few have examined the tribe with such accuracy.

Arrangement and Characters.

By the one view this order is allied to the Flacourtianæ, and by the other to the Guttiferæ, next to which it has been usually placed.—Nothing is known of their properties.

Order 40. *Hippocrateaceæ*. JUSS.

Sepals five (rarely four or six), small, combined in the middle, persistent: estivation imbricated. Petals equal in number to the stamens: estivation imbricated. Stamens three (rarely four or five): filaments united almost to their apex, forming a tube round the ovary. Ovary triangular, trilobular: ovules erect, four in each cell: style one: stigmas 1-3. Placentæ in the axis. Fruit fleshy, 1-3-celled, or of three samaroid carpels. Seeds about four in each cell or carpel. Albumen none. Embryo straight: radicle next the hilum: cotyledons flat, elliptical, oblong, somewhat fleshy, cohering (at least in the dried plant).—Shrubs arborescent or climbing. Leaves opposite, simple, somewhat coriaceous. Flowers small.—Ex. *Hippocrateæ*, *Salacia*.

The ternary number of the stamens, combined with the quinary number of the sepals and petals, form the grand feature of this order. By most botanists it is supposed to be principally allied to the Acerinæ and Malpighiaceæ; but Brown asserts that it is scarcely distinct from Celastriaceæ, notwithstanding the hypogynous stamens.—The fruit of *Tonsella pyriformis* is rich and sweet flavoured; the nuts of *Hippocrateæ comosa* are also eatable.

Order 41. *Erythroxyleæ*. KUNTH.

Sepals five, combined at the base, persistent: estivation imbricated. Petals five, broad, and with a small scale at the base: estivation slightly twisted. Stamens ten: filaments united at the base into a cup: anthers erect, bilocular, longitudinally and laterally dehiscent. Ovary three-celled, of which two are sometimes abortive: ovule one: styles three, distinct or united: stigmas three. Drupe one-seeded. Seed angular, pendulous. Embryo linear, straight, in the axis of a corneous albumen: radicle elongated, next the hilum: cotyledons linear, flat, foliaceous.—Leaves alternate, rarely opposite.—Ex. *Erythroxylon*, *Sethia*.

Closely allied to Malpighiaceæ by the presence of albumen, sessile petals, and general appearance.—A reddish brown dye is prepared from the bark of *Erythr. suberosum*.

Order 42. *Malpighiaceæ*. JUSS.

Sepals five, slightly combined, persistent: estivation imbricated. Petals five, unguiculate, occasionally wanting. Stamens ten (rarely fewer): filaments distinct, or slightly monadelphous: anthers roundish. Torus usually discoid. Ovary one, usually three-lobed, consisting of three carpels, more or less combined: ovules solitary: styles three, distinct or united. Placentæ in the axis. Fruit dry or fleshy, of three distinct carpels or three-celled, occasionally 1-2-celled by abortion. Seeds solitary, pendulous. Albumen 0. Embryo curved or straight: radicle short, next the hilum: cotyledons foliaceous or thickish.—Small trees or shrubs, sometimes climbing. Leaves simple, opposite, or very rarely alternate, not dotted, usually with stipules. Pedicels articulated in the middle.—Ex. *Malpighia*, *Hiptage*, *Banisteria*.

The sepals are often furnished externally with glands at the base, on which account, and the often samaroid fruit, this order seems allied to Acerinæ. In *Aspicarpa* there is but one stamen.—Little is known of their properties. The Barbadoes cherry, the fruit of the *Malpighia glabra*, is used in Jamaica by way of dessert.

Order 43. *Acerinæ*. JUSS.

Calyx 5-, or rarely 4-9-partite: estivation imbricated. Petals equal in number to the lobes of the calyx with which they alternate, rarely wanting. Stamens definite, usually eight, rarely five or twelve: anthers oblong. Torus

discoid. Ovary two-lobed, two-celled: ovules in pairs, attached to the inner angle: style one: stigmas two, subulate. Fruit of two samaroid carpels, of which the membranous appendage has the lower margin incrassated. Seeds solitary or in pairs, erect. Albumen 0. Embryo curved or convolute: radicle next the hilum: cotyledons foliaceous, wrinkled.—Trees. Leaves opposite, simple, lobed, or pinnatisect, without stipules. Flowers often polygamous.—Ex. *Acer*, *Negundo*, *Dobinea*.

Sugar is extracted in abundance from the *Acer saccharinum* and some other species.

Order 44. *Hippocastanææ*. D. C.

Calyx campanulate, five-lobed: estivation imbricated. Petals five or (by abortion) four, distinct, unequal. Stamens 7-8, distinct, unequal: anthers oval, versatile. Torus discoid. Ovary roundish, three-celled: ovules in pairs: style one, filiform, acute. Fruit coriaceous, 1-2-3-celled, 1-2-3-valved, loculicidal. Seeds solitary, large: testa shining or smooth; hilum broad and pale coloured. Albumen 0. Embryo curved, inverted: radicle conical, curved, turned towards the hilum: cotyledons thick, gibbous, fleshy, cohering, hypogæous: plumula large, two-leaved.—Trees or shrubs. Leaves opposite, 5-7-palmate. Pedicels articulated.—Ex. *Æsculus*, *Pavia*.

Richard, with some justice, unites this to the Malpighiaceæ: indeed they agree in almost every important point, except the habit or general appearance.—The seeds abound in starchy matter, which renders them nutritive: they also contain much potash: they are bitter. The bark of *Æsculus hippocastanum* or Horse-chestnut is bitter, astringent, and febrifugal.

Order 45. *Rhizoboleæ*. D. C.

Sepals five, more or less combined: estivation imbricated. Petals five, thickish, unequal. Stamens indefinite, slightly monadelphous, in a double row, of which the inner is often abortive: anthers roundish, bursting longitudinally. Torus discoid. Ovary four-celled: ovules solitary, peritropous: styles 4: stigmas simple. Fruit of four (or by abortion fewer), indehiscent, one-celled, one-seeded nuts, with a thick, double putamen. Seed reniform, with the funiculus dilated into a spongy excrescence: albumen 0. Embryo very large: radicle constituting nearly the whole of the kernel: cauliculus long, two-edged: cotyledons small, foliaceous, lying in a furrow of the radicle.—Trees. Leaves opposite, palmately compound.—Ex. *Caryocar*.

Somewhat allied to *Mangifera* among the Terebinthaceæ, but particularly to Sapindaceæ. To Hippocastanæ it has also some affinity.—The Souari nut, the produce of the *Car. tomentosum*, is well known as the most delicious of the nut tribe: other species yield a nut perhaps almost as good.

Order 46. *Sapindaceæ*. JUSS.

Sepals 4-5, distinct or slightly cohering at the base: estivation imbricated. Petals generally 4-5, occasionally wanting, sometimes naked, sometimes villous or glandular in the middle, or sometimes with a petaloid scale. Stamens twice as many as the petals, distinct, ascending. Torus discoid, plane, lobed. Ovary roundish, trilobular: ovules usually in pairs, one above the other, ascending: styles three, more or less united at the base: stigmas three. Placentæ in the axis. Fruit fleshy, vesicular, or capsular, 3- (or by abortion 1-2-) celled. Seeds solitary, erect, or resupinate. Albumen 0. Embryo: radicle next the hilum: cotyledons more or less curved on the radicle, sometimes straight.—Leaves alternate, having frequently pellucid lines or dots.—Ex. *Sapindus*, *Paullinia*, *Dodonæa*.

Near to Meliaceæ, and also to some of the Terebinthaceæ.—The leaves and branches are poisonous, but the fruit is eatable, and, of several, is used in desserts. The

Arrangement and Characters.

Litchi, Longan, and Rambutan, are from the genus *Euphorbia*. The fruit of the soap-berry, *Sapindus saponaria*, is saponaceous.

Order 47. *Meliaceæ*. JUSS.

Suborder 1. *Meliæ*. Sepals 4-5, more or less united: estivation imbricated. Petals 4-5, conniving or cohering at the base: estivation valvate. Stamens as many as the petals, or two, three, or four times as many: filaments cohering in a long tube: anthers sessile within the orifice of the tube. Torus sometimes large and cup-shaped. Ovarium single, plurilocular: ovules suspended, solitary, or in pairs: style one: stigmas free or combined. Fruit baccate, drupaceous, or capsular, many- (or by abortion one-) celled; valves when present loculicidal. Seeds apterous. Albumen 0. Embryo straight, inverted: radicle next the hilum.—Leaves alternate or stipulate.—Ex. *Melia*, *Trichilia*.

Suborder 2. *Humiriaceæ*. AD. JUSS. Calyx five-cleft: estivation imbricated. Petals five, alternate with the sepals: estivation imbricated. Stamens five times as many as the petals: filaments combined into a tube: anthers two-celled, with a fleshy connectivum extended beyond the lobes. Torus annular or toothed. Ovarium five-celled: ovules suspended, solitary, or in pairs: style simple: stigma lobed. Fruit drupaceous, five- (or by abortion fewer) celled. Seed with a membranous integument. Embryo straight, oblong, lying in a fleshy albumen: radicle next the hilum.—Leaves alternate, exstipulate: petiole winged.—Ex. *Humiria*.

Suborder 3. *Cedreleæ*. R. BROWN. Calyx five-cleft, persistent: estivation imbricated. Petals five, sessile: estivation imbricated. Stamens ten, combined below into a tube: anthers somewhat sessile, acuminate, bilocular, bursting longitudinally. Torus cup-shaped, ten-plaited. Ovarium five-celled, each cell semibilocular by the inflexion of the placenta: style simple: stigma peltate, five-lobed. Capsule of five valves, septifragal; dissepiments obliterated, except at the base. Placenta laminary, inflected, finally becoming loose, and having two or more seeds on each side. Seeds erect or suspended, winged at one extremity: testa coriaceous. Albumen fleshy, thin, or wanting. Embryo straight, transverse: radicle very small, distant from the hilum: cotyledons flat, very large.—Leaves alternate, exstipulate.—Ex. *Swietenia*, *Cedrela*.

We again unite these three orders, because we do not find any good marks between them. The albuminous seeds and slender embryo chiefly distinguish *Humiriæ* from *Meliæ*; but in *Cedreleæ* the seeds have albumen and want it, and in this tribe the dehiscence of the capsule is not so constant as one would wish; for in *Chloroxylon* (or *Swietenia chloroxylon*) the fruit is loculicidal. The seeds of all, we believe, are anatropous.—The medical properties of this family are little understood; and to judge by those that are known, they are very dissimilar. Thus the bark of *Canella alba* (or false Winter's bark) is aromatic and stimulant; that of *Melia* is nauseous; and of *Swietenia febrifuga*, bitter and febrifuge. The fruits of some few are eatable, and delicious. Mahogany is the wood of *Swietenia Mahogoni*.

Order 48. *Ampelideæ*. RICH.

Calyx small, nearly entire. Petals 4-5, sometimes cohering above, and calyptriform: estivation valvate. Stamens 4-5, opposite to the petals: filaments distinct, or slightly cohering at the base: anthers ovate, versatile. Torus an annular disc, bearing the petals on its exterior, and the stamens on its surface. Ovarium two-celled: ovules in pairs, erect: style one, very short: stigma simple. Berry globose, pulpy, two- (or often by abortion, one-) celled. Seeds 1-4, erect: testa osseous. Albumen horny. Embryo erect: radicle slender: cotyledons lanceolate.—

Climbing shrubs. Leaves, lower ones opposite, upper alternate, with racemes opposite to them, which are sometimes abortive, and change into tendrils.—Ex. *Cissus*, *Vitis*.

This order approaches closely to the *Meliaceæ*; indeed it is difficult to say to which *Leea* ought to be referred, or if it ought not to form a small connecting group. If in that genus we consider the torus to be cup-shaped, bearing the petals on its outside about the middle, we shall have above the insertion of the petals five sessile, adnate, extrorse, anthers; by which view we should have a true member of the *Ampelideæ*: but then the anthers are alternate with the petals, and the plants are not climbing: from *Meliaceæ* it differs rather more. As to *Lasianthera*, too little is known of it to decide upon its affinities.—The vine is so well known that we need not detail its properties.

Order 49. *Geraniaceæ*. JUSS.

Suborder 1. *Geraniæ*. ST HIL. Sepals five, persistent, more or less unequal, or sometimes spurred at the base: estivation imbricated. Petals five (or, by abortion, 4, rarely 0), unguiculate: estivation twisted. Stamens monadelphous, twice or thrice as many as the petals (some occasionally abortive). Ovarium of five carpels, placed round an elongated axis: ovules pendulous, solitary: styles five, cohering round the axis. Fruit cohering round the axis; of five pieces, with a membranous, indehiscent pericarp and indurated style, which finally twists and carries the pericarp along with it. Seed solitary, erect: chalaza close to the hilum. Albumen 0. Embryo curved: radicle at the opposite extremity from the hilum, but pointing towards it: cotyledons next the hilum, foliaceous, convolute, and plaited.—Leaves simple, stipulate, opposite, or alternate, with peduncles opposite to them.—Ex. *Geranium*.

Suborder 2. *Lineæ*. D. C. Sepals 3-4-5, persistent: estivation imbricated. Petals 3-4-5, unguiculate, fugitive: estivation twisted. Stamens as many as the petals, and alternate with them (with intermediate teeth or abortive stamens), arising from an annular torus: anthers ovate, erect. Ovarium with as many (rarely fewer) cells and styles as stamens: stigmas capitate. Capsule generally pointed with the hardened base of the styles, plurilocular: each cell spuriously bilocular, and opening by two valves at the apex. Seeds solitary in each spurious cell, compressed, pendulous. Albumen thin, fleshy. Embryo straight: radicle next the hilum: cotyledons flat.—Leaves entire, alternate, without stipules, sometimes with two glands at the base. Flowers terminal.—Ex. *Linum*.

Suborder 3. *Balsamineæ*. RICH. Sepals five, irregular, deciduous, the two inner and upper connate, the lower spurred: estivation imbricate. Petals four (five, but the fifth abortive), united by pairs. Stamens five: filaments subulate: anthers two-celled, bursting longitudinally. Ovarium solitary, five-celled: ovules numerous: stigma sessile, more or less five-lobed. Fruit capsular, five-celled, five-valved, elastically septifragal. Seeds numerous, suspended. Albumen 0. Embryo straight: radicle next the hilum: cotyledons plano-convex.—Succulent herbaceous plants. Leaves simple, opposite or alternate, exstipulate. Flowers axillary.—Ex. *Impatiens*.

Suborder 4. *Hydrocereæ*. BLUME. Sepals five, deciduous, coloured, unequal, the lowermost spurred: estivation imbricated. Petals five, unequal; the upper arched. Stamens five: filaments connate at the apex: anthers slightly connate, bilocular, bursting at the apex. Ovarium five-celled: ovules pendulous, 2-3 in each cell: stigmas five, sessile, acute. Fruit succulent, five-celled; endocarp hard and osseous. Seeds solitary. Albumen 0. Embryo: radicle next the hilum: cotyledons plano-convex.

Arrange-
ment and
Characters.

—Herbaceous, with angular stems. Leaves alternate, exstipulate.—Ex. *Hydrocera*.

Suborder 5. *Tropæoleæ*. Juss. Sepals five, the upper spurred: estivation imbricate, or rarely valvate. Petals five, unequal, irregular, the two upper sessile, the three lower stalked, or sometimes abortive. Stamens eight, free: anthers erect, bilocular. Torus discoid, almost united with the calyx. Ovary one, triquetrous, of three carpels: ovules solitary, pendulous: style one: stigmas three, acute. Fruit indehiscent, separable from the axis into three pieces (or, by abortion, of one piece). Albumen 0. Embryo large: radicle next the hilum, lying within the projections of the cotyledons, which are straight, thick, and consolidated into one body.—Herbaceous trailing or twining plants. Leaves alternate, exstipulate. Flowers axillary.—Ex. *Tropæolum*.

Suborder 6. *Oxalideæ*. D. C. Sepals five, equal, sometimes slightly cohering at the base, persistent: estivation imbricate. Petals five, equal, unguiculate: estivation twisted. Stamens ten, more or less monadelphous; those opposite the petals longer than the others: anthers erect, bilocular. Ovary five-angled, five-celled: styles five, filiform: stigmas capitate, or slightly bifid. Placentæ in the axis. Capsules membranous, five-celled, 5-10-valved. Seeds several: testa fleshy, bursting elastically. Albumen between cartilaginous and fleshy. Embryo straight, as long as the albumen: radicle long, next the hilum: cotyledons foliaceous.—Leaves compound (or by abortion simple), alternate, seldom opposite or whorled.—Ex. *Oxalis*, *Averrhoa*.

All these suborders may be either considered as parts of one order, or as orders belonging to one class. They are allied on the one hand to Caryophyllæ and Malvææ, and on the other to Rutææ. *Rhynchotheca* has no petals, but certainly belongs to the Geraniææ, although it be difficult to say with which of the above sections it ought to be ranked: the seeds pendulous, albumen fleshy, embryo straight, stamens distinct, and two ovules in each cell, militate against it being placed in Geraniææ; and the cohering styles separate it from Linææ and Oxalideæ. In *Tropæoleæ* the stamens may almost be called perigynous.—Geraniææ possess an astringent principle, and an aromatic and resinous flavour. The mucilaginous diuretic seeds of Linææ, and the purgative leaves of *L. catharticum*, are well known. The fleshy fruit of *Tropæoleæ* is acrid, and used as a cress. The Oxalideæ are acid, and supply the place of sorrel. The leaves of *Ox. acetosella* contain pure oxalic acid.

Order 50. *Pittosporææ*. R. BROWN.

Sepals five, deciduous, distinct, or partially cohering: estivation imbricate. Petals five, sometimes slightly cohering: estivation imbricate. Stamens five, distinct, alternate with the petals. Ovary solitary, 1-2-5-celled: style one: stigmas 2-5, equal in number to the placentas. Fruit capsular or baccate, cells polyspermous, sometimes incomplete, loculicidal. Seeds often covered with a glutinous or resinous pulp. Embryo minute, contained in a fleshy albumen near the hilum: radicle long: cotyledons very short.—Leaves simple, alternate, exstipulate. Flowers sometimes polygamous.—Ex. *Pittosporum*, *Billardiera*.

De Candolle arranges this next Polygalææ, probably on account of the tendency of the fruit to become unilocular, with parietal placentæ. We, however, agree with Richard, that its place ought to be at no great distance from the Rutææ.—The berries of *Billardiera* are eatable, but nothing further is known of the properties of the order.

Order 51. *Brexiaceæ*. LINDL.

Sepals five, small, persistent, cohering at the base: estivation imbricate. Petals five: estivation imbricate. Stamens five, alternate with the petals, arising from a

narrow cup, which is toothed between each stamen: anthers introrse, two-celled, opening longitudinally. Ovary five-celled: ovules numerous: placentæ in the axis: style one: stigma simple. Fruit a five-celled drupe. Seeds indefinite: testa and tegmen distinct. Albumen 0. Embryo straight: radicle cylindrical, pointing to the hilum: cotyledons ovate, obtuse.—Trees. Leaves coriaceous, alternate, with small deciduous stipules.—Ex. *Brexia*.

The solitary genus of this order appears to be the same with the *Venana* of Lamarck, which name ought perhaps to be adopted. Du Petit Thouars describes a fleshy albumen.

Order 52. *Rutaceæ*. Juss.

Suborder 1. *Zygophyllææ*. R. BROWN. Flowers bisexual, regular. Calyx 4-5-divided: estivation convolute. Petals alternate with the sepals: estivation usually convolute. Stamens twice as many as the petals: filaments distinct, dilated at the base, and usually arising from scales. Ovary simple, 4-5-celled: ovules in pairs or more, pendulous, or rarely erect: style simple, 4-5-furrowed: stigma simple, or 4-5-lobed. Fruit capsular, or rarely fleshy, with 4-5 angles or wings, 4-5-valved and loculicidal, or indehiscent: endocarp and sarcocarp combined. Seeds usually fewer than the ovules. Albumen between fleshy and horny, rarely 0. Embryo green: radicle superior: cotyledons foliaceous.—Leaves opposite, stipulate, not dotted, rarely simple.—Ex. *Zygophyllum*, *Tribulus*.

Suborder 2. *Rutææ*. Juss. Flowers bisexual, regular. Calyx 4-5-divided: estivation imbricate. Petals alternate with the sepals: estivation between twisted and convolute. Stamens twice or thrice as many as the petals. Torus sometimes discoid. Ovary 3-5-lobed, 3-5-celled: ovules in each cell two, or 4-20, pendulous or adnate to the placentæ: styles several, combined upwards: stigma 3-5-angled, or furrowed. Capsule either three-valved and loculicidal, or 4-5-lobed, opening internally at the apex: sarcocarp and endocarp combined. Seeds often fewer than the ovules. Embryo lying within the fleshy albumen: radicle superior: cotyledons flat.—Leaves (with one exception), exstipulate, alternate, usually with pellucid dots.—Ex. *Ruta*, *Peganum*.

Suborder 3. *Diosmeæ*. R. BROWN. Flowers bisexual. Calyx 4-5-divided: estivation imbricate. Petals (rarely wanting), as many as the sepals, distinct, or combined below into a spurious monopetalous corolla: estivation twisted-convolute, or rarely valvate. Stamens as many, or twice as many, as the petals (or fewer by abortion), hypogynous, or rarely perigynous. Torus discoid or urceolate, surrounding the base of the pistillum, free or attached to the calyx, often wanting. Ovaria as many or fewer than the petals, syncarpous, or more or less apocarpous: ovules two, rarely four or one in each, peritropal: styles combined above: stigma simple or dilated. Fruit of 1-5 capsules, cohering, or somewhat distinct: endocarp two-valved, dehiscing at the base, separating from the two-valved sarcocarp. Seeds solitary or in pairs. Albumen 0. Radicle superior.—Leaves exstipulate, opposite or alternate, covered with resinous dots.—Ex. *Dictamnus*, *Diosma*, *Correa*, *Erodia*, *Monniera*.

Suborder 4. *Zanthoxyleææ*. AD. JUSS. Flowers unisexual, regular. Calyx 3-4-5-divided: estivation imbricate. Petals equal in number (rarely none) to the sepals: estivation usually twisted-convolute. Stamens as many, or twice as many, as the petals. Ovaria as many (or fewer) as petals, syncarpous, or partially apocarpous. Ovules, in each two, or rarely four: styles more or less combined. Fruit either baccate or membranous, sometimes of 2-5 cells, sometimes of several drupes or two-

Arrange-
ment and
Character

Arrangement and Characters.

valved capsules, of which the fleshy sarcocarp is partly separable from the endocarp. Seeds solitary or in pairs, pendulous. Embryo lying within a fleshy albumen: radicle superior: cotyledons ovate, flat.—Leaves exstipulate, alternate or opposite, with pellucid dots.—Ex. *Zanthoxylon*, *Brucea*, *Ptelea*.

Suborder 5. *Simaroubeæ*. RICH. Flowers usually bisexual. Calyx 4-5-divided: estivation imbricated. Petals as many as the sepals, spreading, or connivent into a kind of tube: estivation twisted. Stamens twice as numerous: filaments arising from scales: anthers bursting longitudinally. Ovarium stipitate, 4-5-lobed, 4-5-celled: ovules solitary: style simple: stigma 4-5-lobed. Fruit of 4-5 indehiscent drupes arranged round a common receptacle. Seeds pendulous: testa membranous. Albumen none. Radicle superior, short, drawn back within the thick cotyledons.—Leaves alternate, exstipulate, without dots.—Ex. *Quassia*, *Simarouba*.

These five may, if one please, be viewed as orders belonging to one class. The last of them is the most distinct, and is closely allied to the *Ochnaceæ*. Some few *Diosmeæ* have the stamens perigynous, but the great passage to the *Peripetalæ* is through the *Zanthoxylæ*, many of which are very closely allied to the *Terebinthaceæ*.—Of the *Zygo-phylleæ* some are anthelmintic; others are acrid and bitter, and are employed as sudorifics, diaphoretics, or alteratives. Of the *Ruteæ* the common rue is sudorific, anthelmintic, and emmenagogue. The *Diosmeæ* of the Cape are considered antispasmodics; of America, febrifuge: and the root of *Dictamnus* was formerly used as a sudorific and vermifuge. Almost all the *Zanthoxylæ* are aromatic and pungent; some are powerful sudorifics and diaphoretics; of others the bark is bitter. *Brucea* contains a poisonous principle called *Brucia*. The *Simaroubeæ* are all intensely bitter.

Order 53. *Ochnaceæ*. D. C.

Sepals five, persistent: estivation imbricated. Petals equal to or rarely twice as many as the sepals, deciduous, spreading: estivation imbricated. Stamens five, alternate with the petals, or ten, or indefinite: filaments persistent: anthers two-celled, erect, opening by pores. Torus discoid. Carpels as many as petals, seated upon an enlarged tumid gynobase: ovules erect: styles combined into one. Fruit (a sarcobase) of several indehiscent drupaceous carpella, articulated with the gynobase. Seeds solitary. Albumen none. Embryo straight: radicle short, inferior: cotyledons thick.—Leaves alternate, simple, stipulate. Petioles articulated in the middle.—Ex. *Ochna*, *Gomphia*.

Very closely allied to the *Rutaceæ*, but differing by the erect ovule, and the anthers opening by pores. *Walkera* is usually referred here, although the ovules be pendulous and the radicle superior; but perhaps in this order more attention must be paid to the spermic direction of the embryo; for in *Ochnaceæ* and *Walkera*, as well as in *Rutaceæ*, the radicle points to the hilum.—The root and leaves of *Walkera serrata* are bitter, and a decoction tonic, stomachic, and anti-emetic.

Order 54. *Coriariææ*. D. C.

Calyx campanulate, five-parted: estivation imbricate. Petals five, alternate with the lobes of the calyx, very small, fleshy, carinate internally. Stamens ten (in the female flowers barren): filaments filiform, distinct: anthers oblong, two-celled. Ovarium seated on a thickened torus, five-angled, five-celled: ovules solitary, pendulous: style none: stigmas five, opposite the segments of the calyx, long, filiform, glandular. Fruit (in the male flowers abortive) a crustaceous pentachenium, surrounded by the enlarged fleshy petals. Seeds pendulous. Albumen none. Embryo slightly curved: radicle superior: cotyledons

plano-convex.—Shrubs with square branches. Leaves opposite, simple, three-nerved. Buds scaly. Flowers racemose, unisexual: the males with abortive pistilla, the females with abortive stamens.—Ex. *Coriaria*.

Jussieu has pointed out the affinity of this tribe with the *Malpighiaceæ*: with *Rhamneæ* it is also allied; but we think it would be no difficult matter to demonstrate its close relation to *Euphorbiaceæ*. The petals are in a very reduced state, and scarcely differ from what we find in several *Euphorbiaceæ*.—The fruit of *Coriaria myrtifolia* is poisonous.

Arrangement and Characters.

Div. II.—*Dichlamydeæ Calycifloræ*. D. C.

(2. *Peripetalæ*. Juss.)

2. *Peripetalæ*.

Order 55. *Stackhousiææ*. R. BROWN.

Calyx five-cleft, equal, with an inflated tube. Petals five, equal, inserted at the top of the tube of the calyx, unguiculate: claws combined into a tube: limb narrow, spreading. Stamens five, unequal, arising from the throat of the calyx. Ovarium superior, 3-5-lobed; lobes distinct: ovules solitary, erect: styles 3-5, sometimes united at the base: stigmas simple. Fruit of 3-5, indehiscent, winged or apterous pieces, attached to a central persistent column. Embryo erect in the axis of, and about as long as, the fleshy albumen.—Leaves simple, entire, alternate, with lateral minute stipules.—Ex. *Stackhousia*.

Related to the *Celastrineæ*, and also to the *Euphorbiaceæ*; on which last account we have placed it after *Coriariææ*.

Order 56. *Celastrineæ*. R. BROWN.

Suborder 1. *Euonymææ*. D. C. Sepals 4-5: estivation imbricated. Petals 4-5 (rarely none), with a broad base: estivation imbricated. Stamens alternate with the petals: anthers erect. Torus large, expanded, flat. Ovarium superior, immersed in the torus and adhering to it, 3-4-celled: ovules one or many in each cell, attached by a short funiculus to the axis, ascending. Fruit superior, a capsule 3-4-celled, 3-4-valved and loculicidal, or a dry drupe with a 1-2-celled nut. Seeds one or many in each cell, ascending or resupinate, sometimes arillate. Albumen fleshy. Embryo straight: radicle short, inferior: cotyledons flat and thick.—Shrubs. Leaves simple, alternate, or opposite. Ex. *Euonymus*, *Celastrus*.

Suborder 2. *Staphyleææ*. D. C. Sepals five, connected at the base, coloured: estivation imbricated. Petals five, alternate: estivation imbricated. Stamens five, alternate with the petals. Torus a large urceolate disc. Ovarium 2-3-celled, superior: ovules erect: styles 2-3, cohering at the base. Fruit membranous or fleshy, indehiscent, or opening internally, partly abortive. Seeds ascending, roundish, truncate at the hilum: testa bony: hilum large, truncate. Albumen none. Embryo straight: radicle small, inferior: cotyledons thick.—Shrubs. Leaves opposite, pinnate, with common and partial stipules.—Ex. *Staphylea*, *Turpinia*.

Allied to *Hippocrateaceæ*, to *Euphorbiaceæ*, and to *Rhamneæ*. *Ilicineæ* has been now removed from this to the *Hypocorollææ* near to *Ebenaceæ*.—Their medical properties are unknown. The young shoots of *Euonymus Europæus*, termed bois carré, when charred, are used as pencils in some kinds of drawings.

Order 57. *Rhamneææ*. Juss.

Calyx 4-5-cleft: estivation valvate. Petals distinct, cucullate, or convolute, inserted into the throat of the calyx, sometimes wanting. Stamens definite, opposite the petals. Torus a large, flat, or urceolate disc. Ovarium superior or half superior, 2-3-4-celled: ovules solitary, erect. Fruit fleshy, indehiscent, or dry, and separating in three parts. Seeds erect. Albumen fleshy, rarely none. Embryo about as long as the seed: radicle short,

Arrange-
ment and
Characters.

inferior: cotyledons large, flat.—Trees or shrubs often thorny. Leaves simple, alternate (or rarely opposite), minutely stipulate.—Ex. *Rhamnus*, *Phytica*.

Allied to Celestrineæ, to Euphorbiaceæ, to Rosaceæ, and to Byttneriaceæ. The berries of several species of *Rhamnus* are violent purgatives. The fruit of *Zizyphus*, however, is destitute of these qualities, and is both wholesome and pleasant to eat: the Jujube is a species of this genus, as also the Lotus of the classics.

Τὸν δ' ἴσθις λωτοῖο φαγοὶ μελινθεῖα καρπὸν,
οὐκ ἐπ' ἀπαγγίλαι παλιν ἠέλειν, οὐδὲ νεσθῆαι.
ἀλλ' αὐτοῦ βουλόντο μετ' ἀνδράσι λωτοφαγοῖσιν
λωτὸν ἐρεπτομένοι μιν μιν, νοστοῦ τι λαβεῖσθαι.¹

Order 58. *Terebinthaceæ*. JUSS.

Suborder 1. *Anacardiaceæ*. R. BR. Flowers usually unisexual. Calyx usually small, persistent, 5- (sometimes 3-4-7-) divided. Petals equal in number to the sepals (sometimes wanting), perigynous: estivation imbricate. Stamens equal in number to the petals, and alternate, or twice as many or more: filaments distinct or cohering at the base, perigynous (or very rarely hypogynous.) Torus fleshy, annular, or cup-shaped, or inconspicuous. Ovary single (or rarely 5-6), free or rarely adhering to the calyx, 1-celled: ovulum solitary, attached by the funiculus to the base or side of the cell: styles one or three, occasionally four: stigmas as many. Fruit indehiscent, usually drupaceous. Seed ascending, or more frequently pendulous. Albumen none. Radicle superior or inferior, next the hilum (very rarely at the opposite extremity), sometimes curved suddenly back: cotyledons thick and fleshy, or leafy.—Trees or shrubs: juice resinous, gummy, caustic, or milky. Leaves alternate, not dotted.—Ex. *Anacardium* (Plate CXIII.), *Mangifera*, *Rhus*.

Suborder 2. *Spondiaceæ*. KUNTH. Flowers sometimes unisexual. Calyx 5-cleft, regular. Petals 5: estivation between valvate and imbricate. Stamens ten, perigynous. Torus large, discoid, or annular. Ovary superior, sessile, 2-5-celled: ovules solitary, ascending or pendulous: styles five, short: stigmas obtuse. Fruit drupaceous, 2-5-celled. Seed solitary. Albumen none. Radicle pointing to the hilum: cotyledons plano-convex.—Trees. Leaves imparipinnate, alternate, not dotted, exstipulate.—Ex. *Spondias*.

Suborder 3. *Burseraceæ*. KUNTH. Flowers usually bisexual. Calyx persistent, somewhat regular, 2-5-divided. Petals 3-5: estivation usually valvate. Stamens two or four times as many as petals, perigynous. Torus orbicular or annular. Ovary 2-5-celled, superior, sessile: ovules in pairs, collateral, suspended: style one or none: stigma simple or lobed. Fruit drupaceous, 2-5-celled, its outer portion often splitting into valves. Seed solitary. Albumen none. Radicle straight, superior, next the hilum: cotyledons fleshy, or wrinkled and plaited.—Trees or shrubs abounding in balsam, gum, or resin. Leaves alternate, usually not dotted, generally with stipules.—Ex. *Bursera*, *Ikica*.

Suborder 4. *Amyrideæ*. KUNTH. Calyx small, regular, persistent, four-divided. Petals four, inserted at the base of the calyx (hypogynous, KUNTH), equal, narrow at the base: estivation imbricate. Stamens twice as many as the petals, and inserted with them, distinct. Torus thin, discoid, covering the base of the calyx. Ovary superior, sessile, one-celled: ovules two, pendulous: stigma sessile, capitate. Fruit somewhat drupaceous, indehiscent, glandular. Seed one. Albumen none. Radicle superior, next the hilum, very short: cotyledons fleshy.—Resinous trees or shrubs. Leaves opposite, compound, dotted.—Ex. *Amyris*.

We look on these suborders as parts of one order, and ge-

nera occur which show their affinity. Thus the old genus *Amyris* is now split, and placed in the first, third, and fourth of the above. *Poupartia* lies doubtfully between the second and third. *Sorindeja* is placed by Kunth in the first, by Brown and De Candolle in the third; while *Spondias Mangifera*, which probably does not differ, is in the second. As a whole, this order has the seed anatropous: to this there is perhaps one exception in *Schinus*, where Kunth describes the ovule suspended, and the radicle inferior; but this, from its great resemblance to *Durava*, requires to be re-examined. If in *Amyrideæ* the stamens be truly hypogynous, they may be perhaps removed to the vicinity of the *Aurantiaceæ*.—The *Anacardiaceæ* have an acrid, highly poisonous juice. The varnish of Sylhet, and of Martaban, are obtained from species belonging to them. These varnishes are at first white, but afterwards become black, and are dangerous to some constitutions. Mastich is the produce of species of *Pistacia*. The fruit of some kinds, as the Mango, the Cashew-nut, and the *Pistacia*-nut, are eaten. The fruit of some species of *Spondiaceæ*, called Hog-plums, are eatable. *Burseraceæ* have a fragrant juice, that is neither acrid nor staining. Several balsams are obtained from them. The *Amyrideæ* also produce balsams, but the *Am. toxicaria* is said to be poisonous.

Order 59. *Connaraceæ*. R. BROWN.

Flowers bi- (rarely uni-) sexual. Calyx 5-partite, regular, persistent: estivation imbricate or valvular. Petals 5, equal, inserted at the base of the calyx. Stamens twice as many as the petals, inserted with the petals, or somewhat hypogynous: filaments usually arising from a glandular or annular torus (formed by the union of their glandular bases). Ovary apocarpous, solitary, or several: ovules in pairs, collateral, ascending: styles terminal: stigmas obtuse, usually dilated. Capsules 1-5, dehiscing longitudinally at the ventral suture. Seeds solitary, erect, sometimes with an arillus. Albumen none, or fleshy. Radicle superior, at the opposite extremity from the hilum: cotyledons thick when there is no albumen, foliaceous in those with it.—Trees or shrubs, without resinous juices. Leaves compound, alternate, not dotted, exstipulate.—Ex. *Connarus*, *Omphalobium*, *Cnestis*.

This order seems to form the passage from the *Terebinthaceæ* to the *Leguminosæ*: to the last it is so closely allied as scarcely to be sometimes distinguishable from it, except by the radicle being at the opposite end from the hilum. When there is but one capsule, as in *Connarus* (to which may be united the first section of *Omphalobium* of De Candolle), it is opposite the anterior segment of the calyx, as in *Leguminosæ*: when several, as in *Cnestis*, they alternate. Brown thinks the insertion ought to be described as hypogynous.

Order 60. *Leguminosæ*. JUSS.

Calyx five-parted, or toothed, or cleft, with the odd segment anterior: segments often unequal and variously combined. Petals five (or, by abortion, four, three, two, one, or wanting), inserted into the base of the calyx, usually unequal, sometimes variously combined; the odd petal superior. Stamens definite or indefinite, inserted with the petals or sometimes hypogynous, distinct, or monadelphous, or diadelphous, or rarely triadelphous: anthers bilocular, versatile. Ovary superior, one-celled, solitary (or very rarely 2-5): ovules one or many: style simple, proceeding from the upper or ventral suture: stigma simple. Fruit a legume or drupe. Seeds solitary or several, sometimes with an arillus. Albumen none. Embryo straight, or with the radicle bent upon the edge of the cotyledons.—

¹ Homer's *Odyssey*, ix. line 94.

range-
ment and
characters.

Leaves alternate, with usually two stipules at the base of the petiole, and two at the base of each leaflet in the pinnate leaves. Pedicels usually articulated.—Ex. *Pisum*, *Citrus*, *Mimosa*, *Swartzia*, *Cassia*.

This order touches upon many others, but it is particularly allied to the almond tribe among the Rosaceæ, from which, till lately that Mr Brown pointed it out in the relative positions of the calyx and pistillum, no good character had been discovered to separate them.—This family is among the most important to man, whether as affording objects of beauty, of utility, or of nutriment. The bean, the pea, the vetch, and the clover tribe belong to it; as do the logwood, the laburnum, indigo, the tamarind, senna, and the acacias. Its general property is to be wholesome; but there are several exceptions. Thus, the seeds of *Laburnum* and the juice of *Coronilla varia* are poisonous. Senna, obtained from several species of *Cassia*, is purgative; several other plants are also purgative. The pericarp of some contains much tannin. Several kinds of gums and balsams are got from them. But it would consume pages to enumerate all the uses to which this, one of the most extensive orders in the vegetable kingdom, has been applied.

Order 61. *Moringææ*. R. BROWN.

Calyx five-partite: estivation slightly imbricated. Petals five, nearly equal, the upper one ascending. Stamens ten, perigynous: filaments slightly petaloid, callous, and hairy at the base: anthers simple, one-celled, with a thick convex connectivum. Torus fleshy, lining the tube of the calyx. Ovarium superior, stipitate, one-celled: style filiform, terminal, not obliquely inserted, stigma simple. Placentæ three, parietal. Fruit a pod-like capsule, one-celled, three-valved, loculicide. Seeds numerous, half-buried in the fungous substance of the valves. Albumen none. Radicle straight, small: cotyledons fleshy, plano-convex.—Leaves twice or thrice pinnate, with an odd leaflet.—Ex. *Moringa*.

Formerly considered as part of Leguminosæ, but now separated by Mr Brown. It seems, however, to have more affinity with these than with any others; nor do we see in the fruit very grave objections for such a supposition, as the flowers of *Gleditschia* have occasionally two carpels united in the same manner as the three of *Moringa*. The root of *Moringa pterigosperma*, or horse-radish tree, has a warm, biting, and slightly aromatic taste, and is used as a stimulant in paralytic affections and intermittent fevers.

Order 62. *Rosaceæ*. JUSS.

Suborder 1. *Chrysobalanææ*. R. BROWN. Calyx five-lobed, the fifth lobe superior, sometimes bracteolate at the base. Petals five, or wanting, more or less irregular. Stamens definite or indefinite, usually irregular. Ovarium superior, solitary, 1-2-celled, stipitate, the stalk cohering more or less on one side with the calyx: ovules in pairs, erect: style single, arising from the base of the ovary: stigma simple. Drupe 1-2-celled. Seeds usually solitary, erect. Albumen none, or rarely fleshy. Radicle inferior: cotyledons fleshy.—Trees or shrubs. Leaves simple, alternate, stipulate, without glands.—Ex. *Chrysobalanus*, *Hirtella*.

Suborder 2. *Amygdalææ*. JUSS. Calyx five-toothed, the odd lobe superior. Petals five. Stamens about twenty, in estivation curved inwards: anthers erect, two-celled. Torus lining the tube of the calyx. Ovarium superior, solitary, simple, one-celled: ovules two, suspended: styles terminal, with a groove on each side: stigma reniform. Fruit a drupe. Seeds usually solitary, suspended from the funiculus, which arises from the base of the cavity, but coheres with its side. Albumen none. Embryo straight: radicle next the hilum: cotyledons thick.—Trees or shrubs. Leaves simple, alternate, stipulate.—Ex. *Prunus*, *Amygdalus*.

Arrange-
ment and
characters.

Suborder 3. *Neillieæ*. Calyx campanulate, five-cleft, the odd segment superior. Petals five, sessile. Stamens indefinite, unequal: filaments smooth: anthers erect, bilocular, dehiscing on the outside longitudinally. Torus lining the tube of the calyx. Ovarium superior, simple, one-celled: ovules several, ascending: style round, terminal, persistent: stigma simple, obtuse. Capsule one-celled, dehiscing at the inner or ventral suture. Seeds several. Albumen copious, fleshy. Embryo in the axis of the albumen: radicle next the hilum, thick, short: cotyledons plano-convex.—Shrubs. Leaves simple, alternate, stipulate.—Ex. *Neillia*.

Suborder 4. *Spirææ*. JUSS. Calyx 4-5-lobed, fifth lobe superior: estivation imbricated. Petals five, equal. Stamens indefinite, in estivation curved inwards: anthers erect, two-celled, bursting longitudinally. Torus thin or fleshy, lining the whole tube of the calyx, or free in its upper part. Ovaria superior, one or several, apocarpous, or rarely cohering: ovules 1-6 in each carpel, suspended: styles lateral, but near the apex: stigmas simple, emarginate. Fruit usually of distinct follicles, very rarely capsular. Seeds 1-6, apterous, or rarely winged. Albumen none. Embryo straight: radicle next the hilum: cotyledons flat.—Leaves alternate, stipulate, or rarely without stipules, simple, or rarely trifoliate.—Ex. *Spiræa*, *Gillenia*.

Suborder 5. *Quillajææ*. DON. Calyx five-cleft: estivation valvate. Petals five, alternate with the segments of the calyx, sometimes wanting. Stamens two or three times as many as the segments of the calyx, perigynous: anthers two-celled. Ovaria five, connate at the base, one-celled: ovules indefinite, ascending: styles five: stigmas five, lateral, papillose. Fruit of five follicles, connate at their base. Seeds numerous, ascending, winged at the apex. Albumen none. Embryo straight: radicle cylindrical, next the hilum: cotyledons foliaceous, convolute, longer than the radicle.—Trees. Leaves alternate, entire. Stipules minute, caducous. Flowers unisexual.—Ex. *Quillaja*, *Kageneckia*.

Suborder 6. *Sanguisorbææ*. JUSS. Calyx 3-4-5-lobed, with a thickened, afterwards indurated, tube: estivation valvate. Petals none. Stamens definite, alternating with the segments of the calyx (though sometimes fewer than them by abortion), rarely indefinite: anthers erect, two-celled and bursting longitudinally, or one-celled and bursting transversely. Torus lining the tube of the calyx. Ovarium 1-4, with a lateral style proceeding from the apex or base: ovule solitary, attached to the ovarium, close to the base of the style: stigma simple, penicilliform, or bearded, or rarely capitate. Nuts 1-4. Seed solitary, suspended, or ascending. Albumen none. Radicle superior: cotyledons large, plano-convex.—Leaves alternate, stipulate, simple, lobed, or compound. Flowers often unisexual.—Ex. *Sanguisorba*, *Acana*.

Suborder 7. *Potentillææ*. JUSS. Calyx 4-5- (or more-) divided: estivation valvate. Petals as many as the lobes of the calyx, and alternating. Stamens indefinite, sometimes 10-15-20, rarely five, and then alternate with the petals: anthers bilocular. Torus lining the tube of the calyx, sometimes becoming very fleshy: ovaria distinct, indefinite, or rarely definite (2-5): ovules suspended, erect, or ascending, solitary, or rarely in pairs, one above the other: style lateral, attached near the apex: stigma simple or plumose. Fruit of small nuts or achenia. Seeds solitary. Albumen none. Embryo straight: radicle next the hilum: cotyledons flat.—Leaves alternate, often compound, stipulate.—Ex. *Potentilla*, *Dryas*, *Fragaria*.

Suborder 8. *Rosææ*. JUSS. Calyx five-divided, segments often pinnatisect; tube contracted at the mouth, at length fleshy: estivation spirally imbricated. Petals five. Stamens indefinite: anthers two-celled. Torus

Arrange-
ment and
Characters.

thick, lining the tube of the calyx, bearing at its margin the stamens and petals, and on its surface the carpels. Ovaries superior, indefinite, concealed within the tube of the calyx: ovules in pairs, one above the other, suspended: styles persistent, lateral, attached near the apex of the ovary, protruded beyond the tube of the calyx, and their upper portions free or rarely concrete. Achenia numerous, hairy. Seed solitary. Albumen none. Embryo straight: radicle superior: cotyledons flat.—Ex. *Rosa*.

Suborder 9. *Pomaceæ*. JUSS. Calyx five-toothed, the odd segment superior: tube more or less globose, extremely fleshy and juicy. Petals five, unguiculate. Stamens indefinite. Torus thin, lining the tube of the calyx, bearing the petals and stamens on its margin. Ovaria 1-5, adhering to the side of the calyx: ovules ascending, two collateral, or rarely solitary: styles 1-5: stigmas simple. Fruit a pomum, 1-5-celled, or spuriously 10-celled: endocarp cartilaginous, spongy, or bony. Seeds solitary. Albumen none. Radicle short, next the hilum: cotyledons flat, or rarely convolute.—Trees or shrubs. Leaves alternate, stipulate.—Ex. *Pyrus*, *Crateagus*.

These nine suborders we do not hesitate in thinking portions of one; nor are genuine marks to be found between them. The most distinct is the Chrysobalanæ: the Neillieæ form a passage to the Homalineæ: but as for the others, we do not see how they are to be limited *inter se*. The true Sanguisorbeæ have no petals, few stamens, and definite ovaria; while the Potentillæ ought to have petals, numerous stamens, and numerous carpels: but *Cercocarpus* having no petals, has many stamens; *Sibbaldia* has petals, with five stamens and carpels; *Arenaria* has petals, definite stamens, and two carpels; thus leaving between the two suborders no character but in the presence or absence of the petals. Nor is Roseæ scarcely distinct on the one hand from Potentillæ, and on the other from Pomaceæ. Neuradæ we have referred to the Ficoideæ.—As to properties, the fruit of some of the Chrysobalanæ is eaten under the name of the cocoa-plum. Amygdalæ, including the Plum, Cherry, Almond, Peach, &c. are well known: the leaves and kernel contain hydrocyanic acid, and are usually poisonous. The other suborders are in general wholesome: they contain an astringent principle, on account of which some are used as febrifuges: the roots of a few are emetic.

Order 63. *Calycanthææ*. LINDL.

Sepals and petals confounded, indefinite, combined in a fleshy tube: estivation imbricate. Stamens indefinite, perigynous: anthers extrorse, bursting longitudinally. Torus lining the tube of the calyx. Ovaria several, simple, one-celled, adhering to the tube of the calyx: ovules solitary, or in pairs, one above the other: style terminal. Achenia inclosed within the fleshy tube of the calyx. Seed solitary. Albumen 0. Embryo straight: radicle inferior: cotyledons convolute.—Shrubs with square stems. Leaves opposite, simple, scabious, exstipulate. Flowers bisexual, axillary, solitary.—Ex. *Calycanthus*, *Chimonanthus*.

Most nearly allied to the Rosaceæ, although in some points they bear a resemblance to the Monimiæ: even to the Magnoliaceæ there is an affinity through *Illicium*. The aromatic fragrance of the flowers is the only known property.

Order 64. *Salicariææ*.¹ JUSS.

Suborder 1. *Lythrarieæ*. JUSS. Calyx tubular or campanulate, lobed, the lobes sometimes with intermediate ac-

cessory lobes or teeth: estivation valvate. Petals alternate with the lobes of the calyx, very deciduous, sometimes wanting. Stamens inserted a little below the petals, equal in number to them, or two, three, or four times as many, rarely fewer: anthers introrse, bilocular, bursting longitudinally. Ovarium superior, 2-4-celled: ovules numerous: style filiform: stigma usually capitate. Placentæ in the axis. Capsule membranous, surrounded by, but not combined with, the calyx; usually one-celled by the obliteration of the dissepiments, bursting longitudinally or irregularly. Seeds numerous, small, apterous or winged. Albumen none. Embryo straight: radicle next the hilum: cotyledons flat and foliaceous.—Herbs or shrubs with usually tetragonal branches. Leaves opposite or (seldom) alternate, entire, exstipulate, and without glands. Flowers bisexual.—Ex. *Lythrum*, *Lagerstræmia*.

Suborder 2. *Ceratophylleæ*. GRAY. Calyx 10-12-partite, lobes equal. Petals none. Stamens 12-20: anthers ovato-oblong, bilocular, bicuspidate, sessile. Ovarium free, ovate, one-celled: ovule solitary, pendulous: style filiform, oblique: stigma simple. Nut one-celled, indehiscent, terminated by the indurated style. Seed solitary, pendulous. Albumen none. Embryo straight: radicle superior: cotyledons four! alternately smaller.—Aquatic herbs. Leaves verticillate, cut into filiform lobes. Flowers unisexual.—Ex. *Ceratophyllum*.

Much as these two suborders differ in appearance, we have the authority of Richard for uniting them. It must be confessed, however, that their chief great resemblance is in the persistent calyx, free from, but surrounding, the fruit.—*Lythrum Salicaria* is astringent: a few species of the order are used for dyeing.

Order 65. *Rhizophoreæ*. R. BROWN.

Calyx 4-13-lobed: estivation valvate, or sometimes calyptriform. Petals inserted on the calyx, alternate with the lobes, and equal to them in number. Stamens inserted with the petals, twice or thrice as many: filaments distinct, subulate: anthers erect, straight, or incurved. Ovarium two-celled, adherent to the calyx, or (rarely) free: ovules two or more in each cell, pendulous. Fruit indehiscent, one-celled. Seed pendulous, solitary. Albumen none. Radicle long: cotyledons flat.—Trees or shrubs. Leaves simple, opposite, with stipules between the petioles.—Ex. *Rhizophora*.

Allied on the one hand to Salicariææ, and on the other to Saxifrageæ (Cunoniææ): to Vochysiaceæ and Combretaceæ its affinity is also strong.—The bark is astringent, and in some cases is used for dyeing black.

Order 66. *Vochysiaceæ*. ST HILAIRE.

Sepals 4-5, unequal, united at the base, the upper one spurred: estivation imbricate. Petals one, two, three, or five, alternate with and inserted into the base of the sepals, unequal. Stamens 1-5, opposite to or alternate with the petals, for the most part sterile, one having an ovate, fertile, four-celled anther. Ovarium free, or adherent to the calyx, three-celled: ovules solitary or in pairs, rarely more: style and stigma one. Placentæ in the axis. Capsule triquetrous, three-celled, three-valved, loculicidal, or rarely septicidal. Seeds usually 1-2 (rarely many) in each cell, erect (LINDL.). Albumen none. Embryo straight: radicle short, superior: cotyledons large, foliaceous, convolute, plicate.—Trees. Leaves opposite, entire, stipulate (very rarely exstipulate).—Ex. *Vochysia*, *Qualea*.

An order as yet ill understood, but seemingly most allied to Combretaceæ and Onagrarieæ.

¹ We have arranged this and the fifteen following orders somewhat differently from what De Candolle has done; but we trust they are disposed in a more natural series.

Order 67. *Combretaceæ*. R. BROWN.

Calyx 4-5-lobed, lobes deciduous. Petals alternate with the lobes, or wanting. Stamens twice as many as the lobes, rarely equal in number to them or thrice as many: filaments distinct, subulate: anthers bilocular, bursting longitudinally. Ovarium adherent with the tube of the calyx, one-celled: ovules 2-4, pendulous from the apex of the cavity: style one, slender: stigma simple. Fruit drupaceous, baccate, or nut-like, one-celled, indehiscent, often winged. Seed solitary (by abortion), pendulous. Albumen none. Radicle superior: cotyledons leafy, usually convolute, sometimes plicate.—Trees or shrubs. Leaves alternate or opposite, exstipulate.—Ex. *Combretum*, *Terminalia*.

Allied to Onagraceæ, Memecyleæ, Myrtaceæ, and even to Santalaceæ and Elæagneæ.—The species of this order are mostly astringents: the bark, therefore, of some is used for tanning; others are employed in dyeing. *Terminalia Vernix* is said to furnish the Chinese varnish, which is poisonous.

Order 68. *Memecyleæ*. D. C.

Calyx 4-5-lobed or toothed. Petals 4-5, alternate with the sepals. Stamens twice as many as the petals: filaments distinct: anthers incurved, two-celled. Ovarium 2-8-celled, adherent with the tube of the calyx: ovules solitary: style one, filiform: stigma simple. Berry (balausta?) crowned by the limb of the calyx, one, four, or eight-celled. Seeds solitary, pendulous. Albumen none. Embryo straight: radicle superior: cotyledons foliaceous, convolute.—Shrubs. Leaves opposite, simple, entire, without stipules or dots, penninerved or rarely three-nerved.—Ex. *Memecylon*, *Mouriria*.

Near Myrtaceæ and Melastomaceæ, and in some respects intermediate.

Order 69. *Melastomaceæ*. JUSS.

Calyx with four or five teeth or divisions, which are more or less deep, or are sometimes united and separate from the tube like a lid. Petals equal to the segments of the calyx, perigynous. Stamens equal in number to the petals, and alternate with them, usually with intermediate sterile ones: filaments in estivation bent downwards between the carpels and the calyx: anthers long, two-celled, usually bursting by two terminal pores, sometimes longitudinally. Ovarium with several cells, more or less cohering with the calyx by its angles, but otherwise free: ovules indefinite: style one: stigma simple, entire, punctiform or capitate. Placentæ in the axis. Fruit plurilocular, either free, and then capsular, valvate, and loculicidal, or adherent, baccate (a balausta), and indehiscent. Seeds numerous, minute. Albumen 0. Embryo straight or curved: radicle pointing to the hilum: cotyledons equal or unequal.—Leaves opposite, undivided, not dotted, 3-9-nerved.—Ex. *Melastoma*, *Rhexia*, *Chorizanthe*.

Bordering on both the Salicariæ and Myrtaceæ, but differing from these and other allied orders in several particulars. The great characteristic of this order is the singular situation of the filaments in estivation.—There are no unwholesome species in this large family, and the succulent fruit of several is eatable and pleasant. They all possess a slight degree of astringency.

Order 70. *Alangieæ*. D. C.

Calyx campanulate, 5-10-toothed, with an annular fleshy disc, or continuation of the torus at the base of the segments. Petals as many as the segments of the calyx, linear, reflexed: estivation twisted. Stamens long, exserted, two or four times as many as the petals: filaments distinct, villous at the base: anthers introrse, two-

celled, often sterile. Ovarium globose: style one, subulate: stigma capitate or conical. Berry (balausta) oval, coherent with the tube of the calyx, and somewhat crowned by its limb, fleshy, slightly ribbed, 1-3-celled: endocarp sometimes osseous, and separating from the sarcocarp like a putamen. Seeds solitary, pendulous. Albumen fleshy, brittle. Embryo straight: radicle long, ascending: cotyledons flat, foliaceous.—Trees. Leaves alternate, exstipulate, entire, not dotted.—Ex. *Alangium*.

Closely allied to the Melastomaceæ, from which they differ in very few particulars. To Myrtaceæ they also bear so strong a resemblance, that till lately they were inserted in that order.—The fruit is eatable. The juice of the root is said to be vermifuge and hydragogic; and the root itself, in powder, efficacious against the bite of serpents.

Order 71. *Philadelphææ*. DON.

Calyx 4-10-divided. Petals alternate with the segments of the calyx, and equal to them in number: estivation convolute-imbricate. Stamens indefinite, in one or two rows, or rarely ten. Ovarium coherent with the tube of the calyx: styles distinct, or united into one: stigmas 4-10. Capsule free above, 4-5-celled. Seeds indefinite, scobiform, subulate, smooth, pendulous, heaped in the inner angle of the cells upon an angular placenta: arillus loose, membranous. Albumen fleshy. Embryo straight, about as long as the albumen: radicle superior, obtuse: cotyledons flat, shorter than the radicle.—Shrubs. Leaves deciduous, opposite, without dots or stipules.—Ex. *Philadelphus*, *Deutzia*, *Decumaria*.

This small order borders on the Myrtaceæ, and also on the Saxifrageæ. *Decumaria* is usually described with a fruit of 7-10 cells, but Mr Don¹ asserts it has but four. Mr Lindley doubts if the cover to the seed be an arillus; but if it were the testa, then the interior portion could not have been attached next the hilum, as in these plants, in order to have produced a radicle pointing also towards it.

Order 72. *Myrtaceæ*. JUSS.

Calyx 4-5-6-8-cleft, the limb sometimes cohering in two portions, sometimes in one, and then falling off like a cap or lid. Petals perigynous, as many as the segments of the calyx, and alternating with them, sometimes slightly united at the very base; rarely none: estivation imbricate. Stamens inserted with the petals, twice as many as the petals, or (usually) indefinite: filaments either all distinct, or monadelphous, or variously polyadelphous, in estivation curved inwards. Anthers ovate, bilocular, small, bursting longitudinally. Ovarium cohering with the tube of the calyx, formed of two, four, five, or six carpels, the dissepiments rarely imperfect, and hence one to six-celled: style and stigma simple. Placentæ in the axis. Fruit dry or fleshy, dehiscent or indehiscent, 2-6 or many-celled, or by the obliteration of the dissepiments one-celled. Seeds rarely solitary, or few, usually indefinite. Albumen 0. Embryo straight or curved: radicle next the hilum: cotyledons distinct, or sometimes consolidated into one mass with the radicle.—Trees or shrubs. Leaves usually opposite, entire, and with transparent dots, sometimes alternate, rarely serrated, and rarely without dots.—Ex. *Chamaelaurium*, *Calytrix*: *Leptospermum*, *Eucalyptus*: *Myrtus*, *Eugenia*: *Barringtonia*, *Gustavia*: *Bertholletia*, *Lecythis*.

This very extensive family has been separated into five sections by De Candolle; but, however desirable it might be to erect these into independent orders, no good characters have yet been pointed out. We shall here give a summary of the sections. 1. *Chamaelauriæ* has a one-

¹ Jamieson's Jour. Jan. 1830, p. 170.

Arrange-
ment and
Characters.

celled ovary and capsule, with leaves opposite, and dotted. 2. *Leptospermæ* has a plurilocular capsule, opposite or alternate leaves, which are usually dotted. 3. *Myrtæ* has a berry or balausta, distinct stamens, opposite leaves, which are almost always dotted. 4. *Barringtonæ* has a fleshy, one-celled fruit, monadelphous stamens, opposite or verticillate leaves without dots. 5. *Lecythideæ* has a plurilocular woody capsule that opens with a lid or remains closed, monadelphous stamens, and leaves alternate, and not dotted. To the *Myrtæ* we, with Mr Lindley, unite the *Granatæ*, because *Punica* or the pomegranate only differs by having its two verticels of carpels developed instead of one, as in plants not in a state of cultivation: the inner series (or those at the bottom of the fruit) have their placenta in the axis; but the outer series, forced to the top of the fruit by the contraction of the mouth of the tube of the calyx, having their placenta in the ovary at the back of the inner carpels, exhibit them in the ripe fruit in a horizontal position on the upper surface of the lower cells.—The dots on the leaves and other parts indicate the presence of a volatile oil, which is aromatic and pungent, and gives the perfume to the cloves of commerce, and to several fruits of this order. The fleshy seeds of the *Lecythideæ* are eatable, and highly esteemed.

Order 73. *Onagrarieæ*. JUSS.

Calyx tubular, with the limb usually quadripartite, sometimes sexpartite, very rarely 2-3-partite, the lobes sometimes cohering in various degrees: estivation valvate. Petals usually equal in number to the lobes of the calyx, regular (or rarely irregular), inserted at the top of the tube: estivation twisted. Stamens definite: filaments distinct: anthers oblong or ovate: pollen triangular. Ovary plurilocular, cohering with the tube of the calyx: ovules indefinite, rarely definite: style filiform: stigma capitate or lobed. Fruit baccate or capsular, dehiscent or indehiscent, 1-2-4-celled. Seeds indefinite, rarely definite, or solitary in each cell. Albumen 0. Embryo straight: radicle long and slender, pointing to the hilum: cotyledons short, equal, or rarely unequal.—Leaves alternate or opposite, not dotted.—Ex. *Montinia*, *Fuchsia*, *Epilobium*, *Jussiaea*, *Circæa*, *Trapa*.

Distinguished from *Salicariæ* by the adherent fruit; from *Myrtæ* by the definite stamens and leaves not dotted; from *Haloragæ* by the filiform style and absence of albumen; and from *Loasæ* by the seeds attached to the central axis, and not to the wall of the fruit. With all these, however, *Onagrarieæ* are intimately allied. Lindley has separated from this family *Circæa* and *Trapa*; the former on account of its solitary seeds, but then *Gaura* is in the same predicament. *Trapa* is chiefly remarkable for its very large seeds and unequal cotyledons.—Almost no properties have been recorded of these beautiful plants. The seeds of *Trapa*, which are very large, are eatable.

Order 74. *Haloragææ*. R. BROWN.

Suborder 1. *Cercodææ*. RICH. Calyx with the limb 3-4-partite or entire. Petals inserted at the top of the tube of the calyx, and alternate with its segments, or wanting. Stamens inserted with the petals, twice as many, or equal to them in number, rarely fewer. Ovary closely cohering with the tube of the calyx, 1-3-4-celled: ovules solitary, pendulous: style 0: stigmas equal in number to the cells, papulose on their inner surface, or penicilliform. Fruit dry and indehiscent, membranous or bony, with as many cells as stigmas (rarely fewer by abortion). Seeds solitary, pendulous. Albumen fleshy, sometimes thin. Embryo straight, in the axis of the albumen: radicle superior, long: cotyledons minute.—Leaves alternate, opposite, or whorled. Flowers axillary, sessile, occasionally unisexual.—Ex. *Haloragis*, *Hippuris*, *Myriophyllum*.

Suborder 2. *Callitricheæ*. LINK. Calyx exceedingly minute, inconspicuous, surrounding the ovary, soon rupturing. Petals wanting. Stamen one, rarely two: filament filiform, grooved in the inside: anther reniform, one-celled, bursting transversely. Ovary solitary, tetragonal, compressed, two-celled (of two carpels, the dorsal sutures being slightly inflexed towards the axis): ovules in pairs, peltate: styles none: stigmas two, filiform, papulose on their inner surface. Fruit two-celled, contracted at the dorsal sutures, at once loculicidal and septicidal (thus as if composed of four achenia, attached round the base of the stigmas by the centre of their inner angle). Seeds, two in each cell, divaricating (or in each achenium solitary), peltate. Embryo slightly curved, in the axis of a thin fleshy albumen: radicle superior, long: cotyledons very short.—Aquatic herbaceous plants. Leaves opposite, simple, entire. Flowers axillary, very minute, usually unisexual, sometimes with two small bractæ at the base of the short peduncle.—Ex. *Callitriche*.

Between these two suborders there is little difference except the seeds solitary or in pairs; the last is usually described with four cells to the fruit, although with only two stigmas, an incongruity too obvious to require discussion; the structure is as in the *Boraginææ* and *Labiataæ*. The nearest affinity is with the *Onagrarieæ*, from which they only differ by the presence of albumen, which, however, is sometimes very thin indeed.

Order 75. *Loasææ*. JUSS.

Calyx five-parted, persistent, in estivation spreading. Petals five, cucullate, arising from the top of the tube of the calyx, and alternate with its segments, sometimes with an inner series of five, either similar to the outer or dissimilar: estivation inflexed, valvate. Stamens indefinite, in several rows, distinct, or polyadelphous, each parcel opposite the outer petals: filaments subulate, unequal, the outer ones often sterile. Ovary adherent with the tube of the calyx, or (rarely) only inclosed within it, one-celled: ovules several: styles 3-7, combined into one: stigma one or several. Placenta parietal. Fruit capsular or succulent, one-celled, 3-7-valved, septicidal. Seeds usually indefinite, rarely definite, without an arillus. Embryo in the axis of a fleshy albumen, straight: radicle pointing to the hilum: cotyledons small, flat.—Herbaceous plants, hispid, with sharp stinging hairs. Leaves opposite or alternate. Peduncles axillary, one-flowered.—Ex. *Loasa* (Plate CXVIII.), *Mentzelia*.

This family is most readily distinguished from those, with which it might be otherwise confounded, by the parietal placenta. With *Onagrarieæ* it has much, but with *Cucurbitaceæ*, as we conceive, little affinity. The cuticle of the stem sometimes separates readily while growing.—The stinging property is the only one known.

Order 76. *Cucurbitaceæ*. JUSS.

Calyx 5-toothed, sometimes obsolete. Petals five, distinct or more or less united, sometimes scarcely distinguishable from the calyx, strongly marked with reticulating veins, sometimes fringed. Stamens five, distinct or triadelphous: anthers 2-celled, usually long and sinuous, rarely ovate. Ovary adhering to the tube of the calyx, of 3-5-carpels, spuriously one-celled: ovules solitary or indefinite: style short: stigmas 3-5, two-lobed, very thick, velvety or fringed. Fruit a pepo. Seeds usually ovate and flat, enveloped in a juicy, or dry and membranous, arilla: testa coriaceous, often thick at the margin. Albumen 0. Embryo straight: radicle next the hilum: cotyledons foliaceous, palminerved.—Stem succulent, climbing by means of lateral tendrils formed of abortive stipules. Leaves palminerved, alternate. Flowers usually unisexual.—Ex. *Cucumis*, *Bryonia*.

This order bears considerable affinity to the last. Brown

Arrange-
ment and
Characters.

and Jussieu consider the calyx and corolla together as a double calyx; and were it not for the obvious affinity of Belvisiaceæ, we would have removed it to the Monochlamydeæ.—The melon, the cucumber, and the gourds, come here, of which the uses are well known. Some, as the colocynth, are extremely bitter and purgative. The seeds of all are sweet and oily, and from some a considerable quantity of fine flavoured oil may be expressed.

Order 77. *Papayaceæ*. AGARDH.

Flowers unisexual. Calyx minute, five-toothed. Corolla monopetalous, inserted into the base of the calyx, in the male tubular and five-lobed, in the female divided nearly to the base into five segments. Stamens ten, inserted on the throat of the corolla: anthers introrse, two-celled, bursting longitudinally; those alternate with the lobes of the corolla on short filaments, those opposite to the lobes sessile. Ovarium free, one-celled: ovules indefinite: stigmas sessile, five-lobed, lacerated. Placentas five, parietal. Fruit succulent, indehiscent, one-celled. Seeds indefinite, parietal, enveloped in a loose mucous coat: testa brittle, pitted. Embryo in the axis of a fleshy albumen: radicle slender, turned towards the hilum: cotyledons flat.—Trees without branches. Leaves alternate, lobed, on long slender petioles.—Ex. *Carica* (Plate CXXIV.)

Formerly referred to the neighbourhood of the Urticeæ, but now considered as more allied to the Cucurbitaceæ and Passifloreæ, especially in the structure of its fruit.—The tree yields an acrid milky juice. The fruit is cooked and eaten. Its juice, when unripe, is a very powerful vermifuge. When newly-killed meat of any kind is suspended among the leaves, it in the course of a few hours becomes quite tender.

Order 78. *Belvisiaceæ*. R. BROWN.

Calyx monosepalous, persistent; limb divided. Corolla monopetalous, plaited, deciduous, inserted on the summit of the tube of the calyx. Stamens either indefinite, or ten with an outer row of abortive ones converted into a much lacinated inner monopetalous corolla, distinct or polyadelphous: anthers two-celled. Ovarium adhering to the tube of the calyx, one-celled: ovules indefinite: style one, short: stigma one, lobed or angular. Placentas parietal. Fruit a fleshy berry, crowned by the lobes of the calyx, one-celled. Seeds numerous, parietal.—Shrubs. Leaves alternate, simple, exstipulate. Flowers axillary and solitary, bisexual.—Ex. *Belvisia*, *Asteranthos*.

This small order exhibits much affinity to both Cucurbitaceæ and Passifloreæ. *Belvisia* is the same genus as *Napoleonea*, an older name, and which ought therefore to be retained. A comparison of *Asteranthos* will readily show that the inner corolla of *Belvisia* is, as we have stated, formed of an outer row of stamens.

Order 79. *Passifloreæ*. JUSS.

Sepals five or ten, united below into a more or less elongated tube, in one or two series, the outer being larger and foliaceous, the inner more petaloid, and sometimes wanting. Petals perigynous, usually represented by an annular or many filamentous processes, rarely five, distinct, and with the usual appearance of petals. Stamens five (very rarely indefinite), monadelphous, usually with processes from the torus between them and the petals: anthers versatile, turned outwards, two-celled, bursting longitudinally. Ovarium free, one-celled: ovules indefinite: styles three, or four, or none. Fruit naked or surrounded by the calyx, one-celled, usually three-valved, sometimes deliscent and loculicide, sometimes fleshy and indehiscent. Seeds indefinite, compressed, with an arillus or strophida: testa brittle, sculptured. Embryo straight, in the centre of a thin fleshy albumen: radicle pointing to the hilum.

Tribe 1. *Paropsiæ*. Petals five, membranaceous. Sta-

mens five or numerous: ovarium sessile: stigma of three, four, or five divisions: capsule with as many valves as divisions of the stigma. Seeds with a thick fleshy arilla: cotyledons foliaceous.—Shrubs, not climbing, without tendrils. Leaves alternate, without glands, exstipulate.—Ex. *Patrisia*, *Smeathmannia*.

Tribe 2. *Passifloreæ veræ*. Petals deformed. Stamens five, opposite the outer divisions of the calyx: ovarium stipitate: stigma sessile, three-lobed: capsule three-valved: seeds with a pulpy arillus: cotyledons foliaceous.—Usually climbing plants, with tendrils. Leaves alternate, stipulate, usually with glands on the petioles.—Ex. *Passiflora*, *Tacsonia*.

Tribe 3. *Malesherbiæ*. Calyx tubulous: petals changed into a ten-toothed membranous corona: stamens five, opposite the inner segments of the calyx (DON) or ten: ovarium stipitate: styles three, inserted below the apex of the ovary: capsule three-valved: placentas not higher up than the dehiscence of the valves: seeds strophiolate, cotyledons fleshy.—Suffrutescent plants, not climbing, without tendrils. Leaves alternate, simple, exstipulate, without glands.—Ex. *Malesherbia*.

We think the view we have taken of the corolla is borne out by a comparison of the different genera in this with all those in the allied neighbouring orders. There is a considerable affinity between these and the Violariæ, Flacourtiæ, and Cappariæ; but through *Malesherbia* it is strongest with the Turneraceæ.—In several species the succulent arillus and pulp has been found to be fragrant, cooling, and agreeable to the taste.

Order 80. *Turneraceæ*. D. C.

Calyx with five equal lobes: estivation imbricated. Petals five, inserted into the tube of the calyx: estivation twisted. Stamens five, inserted a little below the petals, and alternating: filaments distinct: anthers oblong, erect, two-celled. Ovarium free, one-celled: ovules indefinite: styles three, more or less cohering, or bifid: stigmas multifid. Placentas three, parietal. Capsule one-celled, three-valved, loculicide, bursting only half-way down. Seeds indefinite, crustaceous, reticulated, with a thin arillus on one side. Embryo slightly curved, in the middle of a fleshy albumen: radicle pointing to the hilum: cotyledons plano-convex.—Herbaceous or suffrutescent plants, pubescent, but not stinging. Leaves alternate, exstipulate, sometimes biglandular at the apex of the petiole.—Ex. *Turnera*, *Piriqueta*.

Considerably allied in habit to the Cistineæ, but differing in several respects in character. Kunth makes it a section of Loasæ; but the hairs are not stinging, the estivation of the corolla is twisted, and the styles only united at the base.

Order 81. *Fouquieriaceæ*. D. C.

Sepals five, persistent, ovate, or roundish: estivation imbricated. Petals five, regular, combined in a long tube, arising from the base of the calyx. Stamens 10-12, exserted, distinct, inserted with the petals, but not cohering with them: anthers two-celled. Ovarium free, sessile, somewhat three-celled: ovules indefinite: style filiform, trifid. Capsule triangular, imperfectly three-celled, three-valved, loculicide. Seeds partly abortive, compressed, winged, pendulous. Embryo straight, in the axis of a thin fleshy albumen: radicle at the opposite extremity from the hilum: cotyledons flat.—Trees or shrubs. Leaves fleshy, clustered in the axilla of a spine or cushion.—Ex. *Fouquieria*, *Bronnia*.

A family very little known, chiefly allied to the Portulacæ and Crassulacæ: to Turneraceæ their affinity is slight, as the fruit is really trilocular, and not one-celled.

Order 82. *Portulacææ*. JUSS.

Sepals two, seldom three or five, cohering at the base.

Arrangement and Characters.

Arrangement and Characters.

Petals usually five, sometimes three, four, or six, or rarely wanting, distinct, or cohering at the base, inserted at the very base of the sepals, sometimes hypogynous, alternate with the sepals when of the same number. Stamens inserted with the petals, variable in number, all fertile: filaments distinct, when definite opposite to the petals or alternating with the sepals: anthers versatile, two-celled, bursting longitudinally. Ovary one, free, one-celled: style single or none: stigmas several. Capsule one-celled, dehiscing transversely (a pyxidium), or by three valves. Seeds numerous or three (solitary? (by abortion), in one plant scarcely known), attached to a central placenta or to the base of the fruit, campulitropous: testa usually crustaceous and black. Embryo curved round the circumference of a farinaceous albumen: radicle long.—Succulent plants. Leaves usually alternate, without stipules, or with scarious ones at each side at the base.—Ex. *Portulaca*, *Talinum*, *Calandrinia* (Plate CXVI.), *Montia*.

This family bears so much affinity to the Caryophyllæ, and to Illecebræ, that it is difficult to discriminate them. Caryophyllæ have, however, no stipules, nor a pyxidium, nor a calyx of two sepals; and the stamens (when few) are opposite to the sepals, and hypogynous. Illecebræ and Scleranthæ, on the other hand, have fertile stamens opposite the sepals, alternating with others that are either fertile or sterile, or with petals, which are sometimes wanting. We exclude from this order the genus *Aylmeria*, of which the two bracteas, five sepals, alternately sterile stamens and scarious stipules, mark it to belong to the Illecebræ near to *Cordia*.—Insipidity and want of smell are the usual qualities of this tribe.

Order 83. *Paronychiaceæ*. ST HIL.

Suborder 1. *Illecebræ*. R. BROWN. Sepals five, sometimes distinct, sometimes more or less cohering. Petals between the lobes of the calyx, sometimes conspicuous, usually small, and resembling sterile stamens, sometimes wanting. Stamens perigynous or hypogynous, opposite the sepals (when equal to them in number), some of them occasionally wanting: filaments distinct, or rarely united: anthers two-celled. Ovary superior: styles two or three, distinct or partially combined. Fruit small, one-celled, an utricle, or a 3-5-valved capsule. Seeds either numerous upon a free central placenta, or solitary and pendulous from a long funiculus arising from the bottom of the fruit. Embryo lying on one side of a farinaceous albumen, more or less curved: radicle pointing to the hilum: cotyledons small.—Leaves opposite or alternate, entire, with scarious stipules.—Ex. *Telephium*, *Illecebrum*, *Polycarpæa*, *Pollichia*.

Suborder 2. *Scleranthæ*. R. BROWN. Sepals 4-5, more or less cohering. Petals between the lobes of the calyx, perigynous, resembling sterile or fertile stamens, sometimes wanting. Stamens equal to the sepals in number, and opposite to them, sometimes fewer: filaments distinct: anthers two-celled, or rarely one-celled. Ovary superior: styles 2-3, distinct, or combined into one. Fruit one-celled, either an utricle covered by the calyx, or a three-valved capsule. Seeds campulitropous, solitary, pendulous from a long funiculus proceeding from the base of the utricle; or one or several attached to a central placenta. Embryo cylindrical, curved round a farinaceous albumen.—Leaves opposite, usually setaceous, without stipules.—Ex. *Scleranthus*, *Queria*, *Minuartia*.

Upon carefully examining these suborders, they will be found to present no difference but the presence or absence of the membranous stipules. These, however, will distinguish the Illecebræ from both the Caryophyllæ and Amaranthaceæ, and the accessory stamens or petals will separate the Scleranthæ from the Chenopodæ. The Paronychiæ, as a whole, form the passage to the Mono-

chlamydeæ; for what are here termed petals or abortive stamens, constitute in the Amaranthaceæ what are often called processes or teeth between the stamens, nor is there any practical difference between them. *Lithophila*, referred here by De Candolle, having three scarious bracteæ, a calyx of five unequal sepals, no corolla, two stamens united at their base with a membranous tube round the ovary, unilocular anthers, an utricular fruit, two long subulate stigmas, and no stipules, evidently belongs to the Amaranthaceæ, next to *Gomphrena*.

Order 84. *Crassulaceæ*. D. C.

Suborder 1. *Sempervivæ*. JUSS. Sepals 3-20, more or less united at the base. Petals equal in number to the sepals, and alternate with them, inserted in the bottom of the calyx, either distinct or cohering in a gamopetalous corolla. Stamens inserted with the petals, equalling them in number, and alternate, or twice as many, those opposite the petals being shortest, and arriving at perfection before the others. Filaments distinct, subulate: anthers bilocular, bursting longitudinally. Nectariferous scales (abortive stamens), one at the base of each ovary, sometimes obsolete. Ovaria equal in number to the petals, and opposite to them, one-celled, tapering each into a short style, distinct, or slightly connected at the base. Fruit of several follicles, opening by the ventral suture. Seeds variable in number. Embryo straight, in the axis of a thin, fleshy albumen: radicle pointing to the hilum.—Leaves succulent (or very rarely membranaceous), entire, or pinnatifid, exstipulate.—Ex. *Crassula*, *Sempervivum*, *Cotyledon*, *Penthorum*.

Suborder 2. *Galacineæ*. DON. Sepals 4-5, united at the base, persistent. Petals as many as the sepals, and inserted upon their bases, alternate with them, caducous. Stamens fertile, either equal in number to and alternate with the petals, or twice as many, inserted along with them, with sterile filaments alternating with them, either distinct or monadelphous: anthers two-celled bursting longitudinally, or one-celled bursting transversely. Ovary 3-4-celled, free: ovules indefinite, attached to the inner angles of the carpels: stigma three-cornered or four-lobed. Fruit of 3-4 follicles attached to each other by their inner angles and the stigma, dehiscing at their ventral and dorsal sutures. Seeds indefinite, minute. Embryo (only observed in *Galax*) straight in the midst of a copious fleshy albumen: radicle long, pointing to the hilum: cotyledons very short.—Herbaceous plants. Leaves radical, simple or pinnatifid, with glandular serratures: stipules none.—Ex. *Francoa*, *Galax*.

These two suborders are principally allied by their carpels not being attached to a central axis or column, and thus bear affinity to the Saxifragæ. The Galacineæ perhaps merit being considered as distinct; but in *Galax* the sterile filaments opposite to the petals have an affinity with the alternate fertile stamens of *Sedum*, a relation which is confirmed by the similarly-situated stamens in *Francoa* being also fertile. In this last genus the sterile filaments are placed between the stamens and petals, and therefore belong, a pair to each petal, and are the choristate lepalis of Dunal: in neither genera are there hypogynous scales, as is usual in the Sempervivæ.—This order possesses refrigerant and abstergent properties, mixed sometimes with a good deal of acidity.

Order 85. *Ficoideæ*. JUSS.

Suborder 1. *Aizoideæ*. SPRENG. Sepals definite (usually five, but varying from four to eight), more or less combined at their base, equal or unequal: estivation valvate or imbricate. Petals indefinite, coloured, sometimes wanting. Stamens perigynous, distinct, definite or indefinite: anthers oblong, incumbent. Ovary cohering with the tube of the calyx, or free, plurilocular (usually five-celled):

stigmata several, distinct. Capsule of several cells bursting in a stellate form at the apex. Seeds usually indefinite, rarely definite, or even solitary. Embryo on the outside of a mealy albumen, curved, or rarely spiral.—Leaves succulent, opposite or alternate, simple.—Ex. *Mesembryanthemum*, *Aizoon*.

Suborder 2. *Nitrariæ*. LINDL. Calyx five-toothed, fleshy, persistent. Petals five, perigynous: estivation inflexed, valvular. Stamens perigynous, three times the number of the petals: anthers erect, bursting longitudinally. Ovary free, three- (rarely six-) celled: ovules pendulous, attached by a long funiculus: style none: stigmata sessile on the attenuated apex of the ovary, as many as there are cells. Fruit drupaceous, one-celled: sarcocarp bursting at the apex by 3-6 valves: endosperm osseous. Seed solitary. Albumen none. Embryo straight: radicle next the hilum.—Shrubs. Leaves deciduous, succulent, alternate, sometimes fascicled.—Ex. *Nitraria*.

Suborder 3. *Neuradæ*. Calyx five-cleft, persistent: estivation slightly imbricated. Petals five, perigynous: estivation imbricated. Stamens ten, perigynous. Ovary syncarpous, cohering at the base with the short tube of the calyx, 5-10-celled: ovules solitary, pendulous: styles 5-10. Capsule 5-10-celled, depressed, indehiscent. Seeds solitary, pendulous, germinating within the capsule. Albumen none. Embryo slightly curved: radicle small, superior, next the hilum: cotyledons large.—Leaves pinnatifid or bipinnatifid, membranaceous, tomentose, stipulate.—Ex. *Neurada*, *Grieliun*.

This order is much allied to the Crassulacæ, but is distinguished by the truly syncarpous ovary; and also to the Portulacæ. The Nitrariæ show an affinity with the Rhamnæ, and the Neuradæ with the Rosacæ.—The succulent leaves of a few are eaten; some yield an abundance of soda.

Order 86. *Cactæ*. JUSS.

Sepals numerous, usually indefinite, and confounded with the petals, either crowning the ovary or covering its whole surface. Petals numerous, usually indefinite, sometimes irregular, inserted at the orifice of the calyx. Stamens indefinite, cohering more or less with the petals and sepals: filaments long, filiform: anthers ovate, versatile. Ovary fleshy, cohering with the tube of the calyx, one-celled: ovules indefinite: style filiform: stigmata several. Placentæ parietal, as many as the stigmata. Fruit succulent, one-celled. Seeds many, after having lost their adhesion nestling in a pulp, ovate or obovate: albumen none. Embryo straight, curved, or spiral: radicle thick, obtuse, next the hilum.—Succulent shrubs. Leaves almost always wanting; when present fleshy, smooth, entire, or spiniform. Flowers sessile.—Ex. *Cactus*, *Rhipsalis*.

Connected chiefly with Grossulariæ, and somewhat with Portulacæ: there is also an affinity with the Ficoideæ. The ovules in *Rhipsalis* are decidedly parietal, notwithstanding that this has been made an exception by De Candolle.—The fruit of several, known under the name of Indian Figs, is eaten: it resembles somewhat that of the Grossulariæ, but is more insipid, and is entirely destitute of the acidity found in that order. It is upon the *Cactus* (*Opuntia*) *Tuna*, and *cochinillifera*, principally, that the cochineal insect feeds.

Order 87. *Grossulariæ*. D. C.

Calyx 4-5-cleft, regular, coloured. Petals perigynous, as many as the segments of the calyx, alternate with them. Stamens 4-5, alternate with the petals, and inserted with them: filaments equal, distinct, usually short: anthers bilocular, bursting longitudinally (or occasionally transversely). Ovary one-celled, cohering with the tube of the calyx: ovules indefinite: style one, 2-4-cleft. Placentas

two, parietal, opposite. Berry crowned with the remains of the flower, one-celled, filled with pulp. Seeds numerous, suspended among the pulp by long filiform recurved funiculi: testa externally gelatinous. Albumen horny. Embryo straight, very minute at the opposite extremity from the hilum: radicle pointing to the hilum.—Shrubs. Leaves alternate, lobed: vernation plicate.—Ex. *Ribes*.

From the Cactæ they may be distinguished by the structure of the seed, and the habit; and from Onagariæ, Homaliniæ, and Loasæ, to all which they are related, by the same and various other characters.—Gooseberries and currants are well known as agreeable acid fruits, owing to the presence of malic acid in them. The black currant is tonic and stimulant, and the leaf is sometimes used to heighten the flavour of bad tea.

Order 88. *Saxifragæ*. JUSS.

Sepals usually five (rarely three, four, seven, or nine), more or less cohering at their base: the limb usually persistent. Petals as many as sepals (except in *Donatia*), inserted on the tube of the calyx, alternate with its lobes, deciduous or persistent, very rarely wanting. Stamens perigynous, either equal to (or rarely fewer than) the petals, and alternate with them; or twice as many as the petals, some alternate, some opposite to them (in one species, by the abortion of the alternating stamens, there are only five, and opposite to the petals); or (in *Bauera*) indefinite: filaments subulate: anthers ovate, two-celled, bursting longitudinally (in *Bauera*) by two pores. Ovary partly coherent with the tube of the calyx, formed of two (rarely 3-5) carpels, cohering by their introflexed sides, or margins: styles as many as the carpels, distinct, or more or less combined: stigmata capitate or clavate. Placentæ along the introflexed margins of the carpels, either throughout the whole length, or at the base only, or at the apex, usually separating with the carpels, rarely attached to a central axis. Fruit capsular, usually of two (rarely 3-5) carpels or valves, the margins of which are either entirely introflexed, or partly introflexed, or scarcely at all when the fruit is one-celled: carpels dehiscing at the ventral suture, separating from each other, either from the base upwards, or from the apex downwards. Seeds usually numerous, rarely definite: albumen fleshy. Embryo small, in the midst of the albumen: radicle pointing towards the hilum.

Tribe 1. *Escalloniæ*. R. BR. Petals and stamens five (rarely six): ovary adherent, or rarely free: styles two or three combined into one.—Shrubs or trees. Leaves alternate, simple, exstipulate.—Ex. *Escallonia*, *Itca*.

Tribe 2. *Cunoniæ*. R. BR. Petals 4-5, or none: stamens 8-10: ovary usually free: styles 2-3, distinct, or rarely combined.—Shrubs or trees. Leaves opposite, with interpetiolar stipules.—Ex. *Cunonia*, *Weinmannia*.

Tribe 3. *Bauerei*. LINDL. Petals 7-9: stamens indefinite: anthers biporse: ovary almost free: styles 2-3, distinct.—Shrubs. Leaves opposite, ternate, exstipulate.—Ex. *Bauera*.

Tribe 4. *Hydrangeæ*. D. C. Petals five: stamens ten: ovary adherent, or rarely free: styles 2-5, distinct, or combined.—Shrubs. Leaves opposite, exstipulate. Flowers corymbose; the exterior, and sometimes all of them, sterile and dilated.—Ex. *Hydrangea*, *Broussaisia*.

Tribe 5. *Saxifragæ*. D. C. Petals 4-5, or wanting: stamens 8-10, or 3-5: ovary adherent or free: styles 2-3, distinct, or rarely combined.—Herbs. Leaves exstipulate, alternate, or rarely opposite. Flowers in a raceme or panicle, rarely solitary, all fertile.—Ex. *Saxifraga*, *Chrysosplenium*, *Heuchera*.

We follow De Candolle in not breaking up this large order, each tribe passing imperceptibly into another. It seems to form a central point between several other or-

Arrangement and Characters.

Arrangement and Characters.

ders. Thus, through Escalloniæ it is allied to the Grossulariæ and Vacciniæ; to the Philadelphæ and Caprifoliæ through Hydrangæ; and to Hypericiniæ through Saxifragæ. De Candolle also compares it with the Umbellifera. The albumen of *Escallonia*, though fleshy, is very oily; and the embryo is in the centre of the albumen, with the radicle pointing to the hilum. Mr Lindley says, erroneously, that the embryo is "in the apex of the albumen, and the radicle at the opposite extremity of the hilum."—The species of Saxifragæ are astringent; the properties of the other tribes are unknown.

Order 89. *Bruniaceæ*. R. BROWN.

Calyx five-cleft: estivation imbricated. Petals alternate with the segments of the calyx, inserted on its throat: estivation imbricated. Stamens alternate with the petals, arising with them, or from a discoid torus: anthers turned inwards, two-celled, bursting longitudinally. Ovarium free, or usually cohering with the tube of the calyx, 1-3-celled: ovules suspended, solitary, or two collateral ones in each cell, very rarely numerous: style simple or bifid: stigmas one, or 2-3, small, and papilliform. Fruit dry, bicoccos, or indehiscent and one-celled, usually crowned by the persistent calyx. Seeds (some of them usually abortive) suspended, sometimes with a short arillus. Embryo minute, at the base (next the hilum) of a fleshy albumen: radicle pointing to the hilum: cotyledons short, fleshy.—Branched, heath-like shrubs. Leaves small, imbricated, rigid, entire. Flowers small, capitate, or rarely paniced, spiked, or terminal, and solitary.—Ex. *Brunia*, *Staavia*, *Berardia*.

An order thought by De Candolle to be allied to Rhamnæ, but now considered as much nearer to Hamamelidæ, or even Myrtacæ. *Thamnea* has a one-celled ovary with a central columnar axis, from the apex of which the ovules hang, indicating a tendency in this order to have a plurilocular fruit.

Order 90. *Hamamelidæ*. R. BROWN.

Calyx four-lobed or truncate, with 5-7 callous teeth. Petals inserted on the calyx, usually long and linear, equal in number to (rarely by abortion fewer), and alternating with, the calycine segments, rarely changed into fertile stamens. Stamens twice as many as the petals; all fertile when the petals bear anthers, half of them (those opposite to the petals) sterile when there are true petals: anthers erect, two-celled, each cell dehiscing longitudinally at the side, either by a valve opening inwards, or by a simple fissure. Ovarium coherent at the base with the tube of the calyx, two-celled: styles two (rarely by accident three). Capsule two-celled, two-valved, loculicide. Seeds solitary, pendulous. Embryo straight, in the axis of a fleshy albumen: radicle superior, next the hilum: cotyledons foliaceous, plane, or slightly involute at their base.—Shrubs. Leaves alternate, petiolate, penninerved, with two stipules. Flowers axillary, nearly sessile, fasciculate, usually with bractæas, sometimes unisexual.—Ex. *Hamamelis*, *Fothergilla*.

The above character is perhaps a little strained to include *Fothergilla*, a genus, however, referred here both by Nuttall and Brown: perhaps it must be even still more modified when *Trichocladus*, another genus of the order, becomes better known. The relation of *Fothergilla* to *Pachysandra* shows some affinity between this family and Euphorbiacæ; and there is a manifest connection also between it and the Amentacæ. There is likewise an affinity to the Alangiæ, Bruniacæ, the Rhamnæ, and the Haloragæ.

Div. II.—*Dichlamydeæ Calycifloræ*. D. C.

(3. Epipetalæ.¹ Juss.)

Order 91. *Umbellifera*. Juss.

Calyx five-toothed, or entire. Petals five, inserted on the outside of a fleshy disc, around the top of the ovary, alternate with the teeth of the calyx, often inflexed at the point, the inflexed portion cohering with the middle vein of the lamina: estivation somewhat imbricate, rarely valvate. Stamens five, alternate with the petals, distinct, during estivation inflexed: anthers ovate, two-celled, dehiscing longitudinally. Ovarium cohering entirely and closely with the calyx, crowned by a double fleshy disc (an expansion of the torus), two-celled: ovules solitary, pendulous: styles two, distinct: stigmas simple. Fruit dry (a *cremocarpium*), consisting of two carpels (or *mericarpia*) which adhere by their face (*commissura*) to a common axis (*carpopodium*), but in maturity separate from it, and are pendulous: each carpel indehiscent, traversed by five longitudinal ridges (*juga primaria*), one opposite to each petal and each stamen; and often also by alternating nerves (*juga secundaria*), the ridges being separated by channels. In the substance of the pericarp are linear receptacles of oily matter (*vitæ*), usually opposite the channels, sometimes below the ridges, rarely wanting. Seed pendulous, usually cohering with the carpel, rarely loose. Embryo minute, at the base (that is, at the apex of the fruit) of a copious horny albumen: radicle superior, pointing to the hilum.—Herbaceous, or rarely suffrutescent plants: stem usually fistular and furrowed. Leaves alternate, very rarely opposite, simple (without articulations), variously cut, sometimes reduced to the petiole (*phylloodium*). Flowers in umbels, the umbel sometimes capitate, usually with an involucre.—Ex. *Conium*, *Eryngium*, *Hydrocotyle*.

Supposed to be allied to Saxifragæ (through *Hydrocotyle*), to Araliacæ, and through them to Ampelidæ. Lindley seems to think them nearest to Ranunculacæ. Perhaps each flower is made up of two, a structure explained by that of *Dampiera* among the Campanulacæ (*Scævolæ*), and rendered probable by that of *Heteromorpha*. Then each petal being formed of two cohering by their margins and an intervening stamen, we should have two flowers each with five petals, five stamens, and one style, united together; and thus other affinities must be looked for.—The fundamental organs of this order are usually very poisonous, at all events ought to be looked on with suspicion, although the roots of a few by cultivation seem to lose their virulent qualities. The fruit is in no case hurtful, and is usually a warm and agreeable aromatic. Gum ammoniac, galbanum, assafœtida, and opoponax, are obtained from plants of this family.

Order 92. *Araliacæ*. Juss.

Calyx entire or toothed. Petals 5-16, alternate with the teeth of the calyx, very rarely wanting, and then (in *Adoxa*) perhaps changed into petals: estivation valvate. Stamens as many as the petals, rarely twice as many, inserted below the margin of a large epigynous disc: anthers two-celled. Ovarium cohering with the tube of the calyx, of two or more cells: ovules solitary, pendulous: styles two or more, distinct, concrete, or rarely wanting: stigmas simple. Fruit usually fleshy, 2-15-celled, crowned by the limb of the calyx: endocarp crustaceous. Seeds solitary, pendulous. Embryo small, surrounded by a copious fleshy albumen, close to the hilum: radicle pointing to the hilum, superior.—Trees, shrubs, or herbaceous plants.

¹ We keep the subdivisions Epipetalæ, Epicorollæ, and Epistamina, although the plants belonging to them have in reality the stamens and petals as much perigynous as the Grossulariæ, Ficoidæ, &c. which have a perfectly adherent fruit.

Arrangement and Characters.
3. Epipetalæ.

Arrangement and Characters.

Leaves alternate, exstipulate. Flowers umbelled or capitate.—Ex. *Aralia*, *Adoxa*, *Hedera*.

This borders strongly on the Umbelliferae, Ampelideae, and also the Corneae.—The famed Ginseng, which, when first introduced into Europe at the beginning of the seventeenth century, sold for its weight in gold, is a species of *Panax*; it is supposed to have a stimulating and invigorating property when fresh, but when dry has now been found of little use. The berries of *Hedera* are purgative.

Order 93. *Corneae*. D.C.

Calyx four-lobed. Petals four, oblong, broad at the base, regular, inserted on the top of the tube of the calyx: estivation valvate. Stamens four, alternate with the petals, inserted with them: anthers two-celled. Ovarium closely cohering with the tube of the calyx, two-celled: ovules pendulous, solitary: style filiform: stigma simple. Fruit fleshy, crowned by the remains of the calyx, two-celled (or rarely one-celled by abortion): endocarp thick and bony. Seeds solitary, pendulous: albumen fleshy. Embryo straight: radicle superior, shorter than the oblong cotyledons.—Trees, shrubs, or herbs. Leaves opposite (in two species only alternate). Flowers capitate, umbelled, or corymbose, naked or with an involucre.—Ex. *Cornus*.

Approaching to the Hamamelideae and Araliaceae (from which it is best distinguished by the opposite leaves, bony endocarp, and a ternary arrangement of the parts of the flower); and also to Caprifoliaceae; but this last has a gamopetalous corolla, and a quinary arrangement in the flowers. One species among the Corneae, however, the *Mastixia pentandra*, is said to have the quinary arrangement and alternate leaves, but is not well known.—The fleshy part of the fruit is sometimes eaten. The bark of *Cornus florida* and *C. sericea* is tonic and febrifuge, and has been substituted in North America for the Peruvian bark.

Div. II.—*Dichlamydeae Calyciflorae*. D. C.

(4. *Epicorollae Corisantherae*. Juss.)

Epicorollae Corisantherae.

Order 94. *Loranthaceae*. Rich. and Juss.

Calyx with a smaller calyx or bractae at the base of its tube; limb short, entire or lobed. Petals 4-8, free or more or less united: estivation valvate. Stamens as many as the petals, and opposite to them: filaments more or less combined with the petals: anthers versatile, or erect, or adnate to the corolla. Ovarium cohering with the tube of the calyx, one-celled: ovule solitary, pendulous: style filiform or none: stigma capitate. Fruit fleshy, crowned by the calyx, one-celled: endocarp membranaceous. Seed one, pendulous. Embryo straight in the axis of a fleshy albumen: radicle superior, next the hilum.—Shrubs almost all parasitical. Leaves fleshy, entire, opposite, rarely alternate or wanting.—Ex. *Viscum*, *Loranthus*.

Distinguished from Caprifoliaceae, Corneae, and the other orders in the neighbourhood, by the position of the stamens before the petals. Mr Brown suggests their relation to Proteaceae.—The berries contain a viscid matter, that is insoluble in water and alcohol. The bark is usually astringent. The well known Mistletoe of the oak is the *Viscum album*. *Loranthus tetrandrus* (the *Lonicera corymbosa* of authors), is used in Chili for dyeing black.

Order 95. *Caprifoliaceae*. Juss.

Calyx with its limb 5- (very rarely 4-) lobed. Corolla of one piece, lobed, sometimes irregular; the divisions alternate with those of the calyx: estivation not valvate

(D. C). Stamens equal in number to the lobes of the corolla (or sometimes one of them abortive), alternating with them, and inserted towards its base: filaments subulate: anthers ovate, bilocular. Ovarium cohering with the tube of the calyx, three-celled (rarely four or five-celled): ovules few in each cell, pendulous: style one, exserted, or none: stigmas as many as the cells, either distinct or combined into one capitate stigma. Fruit crowned by the limb of the calyx, fleshy, or rarely almost dry, plurilocular, or one-celled (either by the disappearance of the dissepiments, or by the abortion of the other cells). Seeds solitary, in pairs, or several (some often abortive) in each cell, pendulous. Embryo straight, in the centre of a fleshy albumen: radicle superior, next the hilum.—Shrubs. Leaves opposite without stipules (or rarely with two small stipules or glands at the base of each petiole). Flowers terminal, corymbose, or axillary.—Ex. *Sambucus*, *Viburnum*, *Lonicera*, *Linnaea*.

Arrangement and Characters.

Tribe 1. *Sambuceae*. KUNTH. Corolla regular, rotate, seldom tubular: style none: stigmas three, sessile; raphe on the inner side of the ovule.

Tribe 2. *Lonicereae*. R. BROWN. Corolla more or less tubular, often irregular: style filiform: raphe on the outer side of the ovule. (Br.)

In *Sambucus* and *Viburnum* the testa of the seed is membranous, but the endocarp is bony: in *Lonicera* and *Triosteum* the testa itself is bony; and care must be had to distinguish whether the bony part belong to the carpel or the seed. This order bears a striking relation to the Rubiaceae; it is also allied to the Apocynae.—The flowers of the elder (*Sambucus nigra*) are fragrant and sudorific, but the leaves emetic and purgative. The fruit of *Viburnum* has an austere astringent pulp, which becomes eatable after fermentation. The honeysuckle is a purgative.

Order 96. *Rubiaceae*. JUSS.

Tube of the calyx adherent with the ovary, the limb variable, truncate, or lobed, consisting of as many sepals as petals, rarely with accessory intermediate teeth. Petals 4-5, rarely 3-8, united, inserted upon the summit of the tube of the calyx: estivation twisted or valvate. Stamens as many as the lobes of the corolla, alternate with them (rarely some of them suppressed): filaments more or less combined with the tube: anthers oval, two-celled, turned inwards: pollen elliptical. Ovarium adherent, usually two-celled, or with several cells, rarely (by abortion) one-celled, crowned by a fleshy urceolate disc: style single, sometimes partly divided: stigmas usually two, rarely several, distinct, or more or less concrete. Fruit a cremocarpium, or capsular, or baccate, or drupaceous, two or many-celled. Seeds one or many in each cell, in the former case attached to the apex, or more usually to the base of the cell; in the latter to a central placenta. Albumen horny or fleshy, copious. Embryo straight or slightly curved, inclosed in the albumen: radicle turned to the hilum: cotyledons foliaceous.—Leaves simple, entire, opposite (very rarely verticillate): stipules two at the base of each leaf, entirely distinct, or cohering either with the leaf or with each other, or both ways; their apex sometimes produced into setae, sometimes into foliaceous expansions, resembling verticillate leaves.—Ex. *Cinchona*, *Gardenia*, *Hedyotis*, *Isertia*, *Hamelia*, *Cordia*, *Guetarda*, *Paderia*, *Coffea*, *Spermacoce*, *Anthospermum*, *Rubia*, *Opercularia*.

The above thirteen genera have been taken by De Candolle¹ as the types of as many tribes, but our limits do

¹ Prodr. Syst. Regn. Veg. vol. iv. p. 342.

Arrange-
ment and
Characters.

not permit us to give the characters. The Rubiaceæ are allied to the Caprifoliaceæ, to Valerianæ, Dipsacæ, and Compositæ; but perhaps it was with the Apocynæ and Gentianæ that they were most generally confounded, previous to the separation of the Loganiaceæ. *Houstonia*, referred still by De Candolle to the Gentianæ, has an inferior (adherent) ovary, interpetiolar stipules, a bilocular polyspermous capsule, and seeds not winged, and consequently must be arranged here, at the end of the Hedyotideæ.—The roots (as in *Rubia* or the Madder) sometimes yield an excellent red dye; in others they are acrid, emetic, purgative, or diuretic. The bark (as in *Cinchona* or Peruvian bark) is sometimes bitter, tonic, astringent, and aromatic, and eminently powerful in intermittent fevers. The horny albumen of the *Coffea Arabica* is what is roasted, and made use of, under the name of Coffee; and it is probable that such other seeds, of this order, as have a horny albumen, might be used as a substitute. The fruit of a few is succulent and eatable.

Order 97. *Valerianæ*. JUSS.

Calyx with a limb of various kinds, either membranous, or resembling a pappus. Corolla inserted into the top of the ovary, tubular, usually five-lobed, rarely 3-4-lobed, lobes obtuse; tube equal, or gibbous, or spurred, at the base. Stamens 1-5, inserted into the tube of the corolla, and alternate with its lobes: anthers ovate, two-celled. Ovary cohering with the tube of the calyx (inferior), 1-3-celled: ovule solitary, pendulous: style filiform: stigmas 1-3, distinct or combined. Fruit dry, indehiscent, crowned with the limb of the calyx, one-celled, or three-celled (two being abortive). Seed solitary, pendulous. Albumen none. Embryo straight: radicle superior: cotyledons flat.—Leaves opposite, exstipulate.—Ex. *Patrinia*, *Valeriana*.

Most intimately connected with Dipsacæ, but distinct by having no albumen, and by the absence of an involucre.—The roots of several are tonic, bitter, vermifuge, and antispasmodic; and some seem to be even febrifugal. The smell is disagreeable, although esteemed in some countries: thus the *Nardostachys Jatamansi* is the spike-nard of the ancients. The young leaves of *Valerianella olitoria* make a good spring salad.

Order 98. *Dipsacæ*. JUSS.

Calyx with a limb short or elongated, entire, or toothed, or papose. Corolla inserted on the apex of the tube of the calyx, tubular, limb oblique, 4-5-lobed, rarely ringent: estivation imbricated. Stamens four, inserted on the tube of the corolla, alternate with its lobes, almost always distinct: anthers two-celled. Ovary cohering with the tube of the calyx, either closely, or only by the apex, or at first free and afterwards cohering, one-celled: ovule solitary, pendulous: style filiform: stigma simple. Fruit dry, indehiscent, crowned by the limb of the calyx, usually covered by an outer calyx or involucre, one-celled. Seed solitary, pendulous. Embryo straight, in the axis of a fleshy albumen: radicle superior.—Leaves opposite, very rarely verticillate, variable in shape on the same plant. Flowers densely capitate, or very rarely verticillate.—Ex. *Morina*, *Scabiosa*.

The involucre to each flower in this order is of a very singular kind, and may be distinguished into three parts: the *base*, or the lower portion; the *tube*, which is furnished with several deep furrows or grooves; and the *crown*, or the portion above the grooves,—the modifications of which are well suited for generic characters. This family is most allied to the Calyceræ and Valerianæ. The teasel (the head of *Dipsacus fullonum*) is used by fullers in dressing cloth.

Div. II.—*Dichlamydeæ Calycifloræ*. D. C.

(5. *Epicorollæ Synantheræ*.)

Order 99. *Calyceræ*. R. BROWN.

Calyx with a limb of five unequal segments. Corolla regular, funnel-shaped, with a long slender tube and a five-lobed limb; the lobes with three principal veins. Stamens five, inserted on the tube, with as many alternating glands inserted a little below them: filaments united: anthers introrse, partially connate. Ovary cohering with the tube of the calyx, crowned by a disc, one-celled: ovule solitary, pendulous: style single, smooth: stigma capitate. Fruit an achenium, crowned by the rigid teeth of the calyx. Seed solitary, pendulous. Embryo in the axis of a fleshy albumen: radicle superior.—Herbaceous plants. Leaves alternate, exstipulate. Flowers sessile, capitate, surrounded by an involucre: sometimes the ovary mutually cohere into one mass.—Ex. *Calycera Boopis*.

In this, the preceding order, and the following, the flowers are sometimes termed florets, and the whole capitulum a flower; but this is incorrect. From Compositæ this order is easily known, by the radicle being superior.

Order 100. *Compositæ*. ADANSON.

Limb of the calyx either wanting or membranous, and divided into bristles, paleæ, or hairs, and called pappus. Corolla monopetalous, five-toothed or lobed, tubular, or ligulate, or bilabiate, inserted on the top of the ovary, alternate with the lobes, which have each two marginal nerves: estivation valvate. Stamens five, alternate with the teeth of the corolla: filaments distinct: anthers connate (very rarely free), erect, articulated with the filaments. Ovary cohering with the tube of the calyx, one-celled: ovule solitary, erect: style single: stigmas two, distinct or united. Fruit an achenium, crowned with the limb of the calyx. Seed solitary, erect. Albumen none. Radicle inferior.—Leaves alternate or opposite, usually simple, exstipulate. Flowers bi- or unisexual, capitate, surrounded by a many-leaved involucre (*bracteoles*), the scales of which are sometimes also interspersed with the flowers on the receptacle, and are then called *paleæ*.—Ex. *Carduus*, *Centaurea*; *Achillea*, *Artemisia*; *Trixis*, *Chaetanthera*; *Sonchus*, *Heiracium*.

Of this there are four principal groups: 1. *Cynarocephalæ*, where the flowers are all tubular, the receptacle hairy or pitted, the style swollen and furnished with hairs below the stigma: 2. *Corymbifereæ*, where the external flowers are usually ligulate, and the inner ones tubular: 3. *Labiatifloræ*, where the flowers have two deep unequal lips to the corolla: 4. *Cichoraceæ*, where all the flowers are ligulate. Various subdivisions have been also attempted, but their limits are hitherto very unsettled.—All the Compositæ are bitter. The Cynarocephalæ are some of them stomachic, others febrifugal, and others sudorific and diaphoretic; but the bitter principle is not found in the unexpanded leaves or receptacle. The Corymbifereæ possess tonic, stomachic, and febrifugal qualities; some are sudorific, others diuretic: the roots of *Helianthus tuberosus*, or the Girasole (*vulgo* Jerusalem) artichoke, are eatable. The Cichoraceæ have usually a milky, bitter, astringent, and narcotic juice, which induces sleep; but before this is formed, many of the species may be used as articles of food.

Div. II.—*Dichlamydeæ Calycifloræ*. D. C.

(6. *Pericorollæ*. JUSS.)

Order 101. *Brunoniaceæ*. R. BROWN.

Calyx five-partite, with four bracteas at its base, persistent: tube very short, afterwards enlarged. Corolla in-

Arrange-
ment and
Characters

5. Epico-
rollæ Sy-
nantheræ

6. Peri-
corollæ

Arrangement and Characters.

serted in the base of the calyx (truly hypogynous?): monopetalous, infundibuliform, nearly regular, marcescent: tube ultimately split at the back, with the primary nerves opposite its divisions: limb five-partite, the upper segments most deeply divided; nerves central, dividing at the top into two recurrent marginal branches: estivation valvular. Stamens five, inserted with, but free from, the corolla, alternating with its segments: filaments very short, distinct: anthers connate, erect, articulated with the filaments, bilocular, bursting longitudinally. Ovarium free, one-celled: ovule solitary, erect: style single: stigma single, inclosed in a two-valved cup (indusium). Fruit a utricle, inclosed in the indurated tube of the calyx. Seed one, erect. Albumen 0. Embryo straight: radicle small, inferior: cotyledons fleshy, plano-convex.—Herbaceous plants, without stems. Leaves radical, exstipulate. Flowers capitate, on a scape: heads surrounded by an involucre of enlarged bractæ.—Ex. *Brunonia*.

Very nearly allied indeed to the Dipsacæ and Compositæ, but having the ovary free. We do not feel quite certain that the corolla is hypogynous, having observed a kind of disc at the base of the calyx, to which it seemed attached; but although it were so, it would be impossible to remove this order from the side of the Goodenoviæ. The habit is that of the Globularinæ. Perhaps this and the three following ought to be made suborders of one great order.

Order 102. *Goodenoviæ*. R. BROWN.

Calyx five-cleft, sometimes 5-3-partite, sometimes obsolete, equal, or rarely unequal, persistent. Corolla inserted into the calyx, sometimes at its base; monopetalous, more or less irregular, marcescent or deciduous: its tube split at the back, and sometimes separable into five petals when the ovary is almost free: its limb five-partite, with one or two lips, the edges of the segments being thinner than the middle: primary nerves of the tube alternate with the divisions; the thick part of the lobes with lateral nerves: estivation valvate. Stamens five, distinct, inserted with, but free from, the corolla, alternate with its lobes: anthers distinct or cohering, continuous with the filaments, two-celled, bursting longitudinally: pollen simple or compound. Ovarium more or less cohering with the tube of the calyx, 1-2 or four-celled, sometimes with a gland between the two anterior filaments: ovules erect: style one, simple (rarely divided): stigma fleshy, simple, or two-lobed, surrounded by a membranous cup. Fruit various. Seeds erect, definite or indefinite: testa thick, sometimes bony. Embryo straight, inclosed in a fleshy albumen: radicle inferior: cotyledons foliaceous.—Plants without milky juice. Leaves scattered, exstipulate. Flowers distinct, never capitate.

Tribe 1. *Goodeniæ*. R. BROWN. Ovarium of two (rarely four) carpels, 2-4-celled: ovules indefinite: fruit a two or rarely four-celled capsule, septicidal, rarely loculicidal: seeds numerous, attached to the axis.—Ex. *Goodenia*, *Velleia*.

Tribe 2. *Scævoleæ*. R. BR. Ovarium of two or four carpels, 1-2 or four-celled: ovules solitary in each carpel: fruit indehiscent, drupaceous, or nut-like: seed one, or two (by abortion of the dissepiment), in each cell, attached to the bottom of the cell.—Ex. *Scævola*, *Dampiera*.

The above two tribes, differing little from each other, but agreeing in a multitude of extraordinary characters, we cannot consider even as suborders. We consider the indusium to the stigma as an abortive gynandrous column, both in this order and the last.

Order 103. *Styldiæ*. R. BROWN.

Calyx with 2-6 divisions, bilabiate or regular, persistent. Corolla monopetalous, falling off late: its limb 5-6-partite, irregular, or rarely equal: lobes with a central nerve:

estivation imbricated. Stamens two: filaments longitudinally connate with the style into a column: anthers didymous, rarely simple, lying over the stigma: pollen globular, simple, sometimes angular. Ovarium cohering with the side of the calyx, crowned often with one gland in front or two opposite ones, two-celled, or, by the contraction of the dissepiment, sometimes one-celled: ovules indefinite: style one: stigma entire or bifid. Capsule two-valved, two or one-celled, septicidal. Seeds indefinite, small, erect. Embryo minute, inclosed in a fleshy, somewhat oily albumen.—Plants, destitute of milky juice. Leaves alternate, scattered, or apparently verticillate.—Ex. *Stygidium*, *Forstera*.

The position of the anthers in this order, combined with the tubæ at the base of the style in some of the Campanulacæ, serves to explain the structure of the indusium to the stigma in the two preceding. This family is readily distinguished by the gynandrous stamens, from those in its vicinity.

Order 104. *Campanulacæ*. JUSS.

Calyx usually five-lobed (sometimes 3-8-lobed), rarely entire, persistent. Corolla monopetalous, inserted on the calyx, usually five (sometimes 3-4-6-8) cleft, deciduous or marcescent: lobes with a central principal nerve: estivation valvate. Stamens inserted with the corolla, alternating with its lobes, and equal to them in number: anthers two-celled, distinct or cohering, erect, two-celled, bursting longitudinally. Ovarium cohering, wholly or by its lower half, with the tube of the calyx, of two or more carpels: ovules indefinite: style simple: stigma naked, simple, or with as many lobes as cells to the ovary. Placentæ in the axis of the plurilocular, or parietal in the one-celled ovary. Fruit capsular, one or more celled, loculicidal, dehiscing either by lateral fissures, or by valves at the apex. Seeds indefinite. Embryo straight, in the axis of a fleshy albumen: radicle pointing to the hilum.—Plants, yielding a milky juice. Leaves alternate or rarely opposite, exstipulate.

Tribe 1. *Lobeliæ*. JUSS. Odd segment of the calyx anterior: corolla irregular: anthers cohering: pollen ovate, elongated, smooth, marked by a longitudinal furrow: style glabrous, with a fringe of hairs below the stigma.—Ex. *Lobelia*.

Tribe 2. *Campanulæ*. D. C. Odd segment of the calyx posterior: corolla regular: anthers free, or rarely cohering: pollen spherical, papillose: style pubescent.—Ex. *Campanula*.

The distinguishing characters of these two tribes are perhaps too few to afford ordinal characters. The hairs on the style or under the stigma seem to be intended for the absorption of the vivifying part of the pollen. There is an expansion of the torus (or abortive stamens) at the insertion of the corolla and stamens, and this sometimes not only covers the top of the ovary, but even forms a tube round the style (as in *Adenophora*). The cells of the fruit are usually opposite the calycine segments, rarely alternate with them. In the *Lobeliæ* the odd sepal is really anterior, although by a twist in the pedicel it appears posterior.—The milky juice is acrid, and in some cases poisonous.

Order 105. *Gesneriæ*. RICH. and JUSS.

Calyx five-parted: estivation valvate. Corolla monopetalous, tubular, more or less irregular, five-lobed: estivation imbricate. Stamens four (rarely two), two being longer than the others, with the rudiment of a fifth inserted on the corolla: anthers two-celled, with a thick tumid connectivum. Ovarium partly free, surrounded by glands alternating with the stamens, of two carpels whose margins are introflexed and placentiferous: ovules indefinite: style continuous with the ovary: stigma capitate,

Arrangement and Characters.

Arrange-ment and Characters. concave. Fruit capsular or succulent, one-celled, two-valved, loculicidal. Seeds minute, indefinite: testa thin, finely and obliquely veined. Embryo in the axis of a fleshy albumen: radicle pointing to the hilum.—Leaves opposite, rugose, exstipulate.—Ex. *Gesnera*, *Sarmienta*, *Gloxinia*.

More allied to the Bignoniaceæ, and especially Orobanchæ, from which last order the present is most readily distinguished by the usually adherent ovary: perhaps, as hinted by Richard, the two orders may be conjoined. Being allied, however, to the Orobanchæ, the Gesneriaceæ form a link between the Campanulaceæ and the following order (Monotropæ).

Order 106. *Ericineæ*. Juss.

Suborder 1. *Monotropææ*. Nutt. Calyx 3-4-5-partite, persistent. Corolla monopetalous, regular, deciduous, more or less deeply 4-5-lobed, inserted at the base of the calyx (hypogynous?): estivation imbricated. Stamens inserted with the corolla, twice as many as its lobes, distinct, free from the corolla: anthers two (often imperfectly) celled, dry, opening by fissures or pores, with or without appendages. Torus discoid. Ovary free, 4-5-celled: ovules indefinite: style one: stigma simple, discoid. Fruit capsular, 4-5-celled, 4-5-valved, loculicidal: axis 4-5-lobed. Seeds indefinite, minute: testa long and linear, loose, membranous, largely reticulated with veins: nucleus globose in the centre of the testa. Albumen fleshy. Embryo at one extremity of the albumen, extremely minute.—Herbaceous, or rarely suffrutescent plants. Leaves simple, entire, or toothed, or wanting.—Ex. *Pyrola*, *Monotropa*.

Suborder 2. *Ericææ*. Calyx 4-5-cleft, nearly equal, persistent. Corolla inserted at the base of the calyx (hypogynous?), monopetalous, 4-5-cleft (occasionally separable into four or five petals), regular or irregular, often marcescent: estivation imbricated. Stamens definite, equal in number to the segments of the corolla, or twice as many, distinct, inserted with the corolla, free from it, or attached to its base: anthers two-celled, hard and dry, usually (rarely not) bifid and furnished with some kind of appendages, dehiscing by terminal pores, or rarely by clefts. Torus discoid, or in the form of scales. Ovary free, plurilocular: ovules indefinite, very rarely solitary in each cell: style one, straight: stigma one, entire or toothed. Placentæ central. Fruit capsular or baccate, with several cells, loculicidal, or septicidal. Seeds indefinite, minute, very rarely definite, testa adhering closely to the tegmen and nucleus. Embryo cylindrical, in the axis of a fleshy albumen: radicle next the hilum.—Shrubby or suffrutescent plants. Leaves evergreen, rigid, entire, whorled, or opposite, exstipulate.—Ex. *Erica*, *Arbutus*, *Rhododendrum*, *Andromeda* (Plate CXXIV.)

Suborder 3. *Vacciniææ*. D. C. Calyx entire, or 4-6-lobed. Corolla monopetalous, with as many lobes as the calyx. Stamens distinct, twice as many as the lobes of the corolla: anthers dry, two-celled, deeply bifid, with narrow horn-like lobes. Torus forming a disc round the top of the ovary. Ovary adherent to the tube of the calyx, 4-5-celled: ovules indefinite: style simple: stigma simple. Fruit baccate, crowned by the persistent limb of the calyx, succulent, 4-5-celled. Seeds numerous. Embryo straight, in the axis of a fleshy albumen: radicle long, pointing to the hilum: cotyledons very short.—Ex. *Vaccinium*, *Oxycoccus*.

Suborder 4. *Epacrideææ*. R. Br. Calyx five- (rarely four-) parted, often coloured, persistent. Corolla inserted at the base of the calyx (hypogynous?), deciduous or marcescent, monopetalous, sometimes separable into five petals; limb five (rarely four), divided, sometimes by the cohesion of the segments, bursting transversely: estivation imbricated or valvular. Stamens as many as, and al-

ternate with, the segments of the corolla, rarely fewer, inserted with or on the corolla: anthers dry, simple, entire, without appendages, bursting longitudinally: pollen round or three-lobed, attached to a single central receptacle. Torus in the form of scales. Ovary sessile, free, plurilocular (rarely uni-) locular: ovules solitary or indefinite: style one: stigma simple, or sometimes toothed. Fruit drupaceous, baccate, or capsular. Embryo slender, straight, in the axis of a fleshy albumen, and about half its length.—Shrubs or small trees. Leaves usually alternate, exstipulate.—Ex. *Epacris*, *Styphelia*.

Between Monotropææ and Ericææ there is no certain character but in the testa of the seed; the mode by which the anthers dehisce being variable in both, even although we exclude *Pyrola*, as has been already done by Don. Ericææ is usually described with indefinite ovules; but *Cyrtilla*, usually referred here, has them solitary in each cell. Between Ericææ and Vacciniææ no character can be given, farther than the ovary free or adherent: the habit of several species in both is the same. Between Ericææ and Epacrideææ, again, there is almost nothing but the structure of the anthers and a difference of habit; we therefore consider them all as suborders. As a whole, it is difficult to say what are the affinities. In some points they slightly approach to the Campanulaceæ, and in others to the Saxifrageæ (Escalloniææ and Cunoniææ).—Their general properties are astringent and diuretic. The berries of the succulent fruited species are mostly grateful and eatable: the Bilberries, Cranberries, Bearberries, &c. belong to this family. The fruit of the *Arbutus unedo* (so called because one was sufficient) is, however, exceedingly disagreeable.

Order 107. *Columelliæææ*. Don.

Calyx turbinate; limb persistent, five-lobed, or multi- (10-11-) partite. Corolla perigynous, rotate, 5-8-lobed: estivation convolute. Stamens two, inserted in the throat of the corolla: anthers linear, sinuous, and one-celled, or straight and two-celled. Torus expanded into a perigynous disc. Ovary cohering with the tube of the calyx, two-celled: ovules indefinite (Don): style simple, declinate: stigma capitate. Fruit capsular, two-celled, two-valved, septicidal, each valve often splitting at the apex. Seeds indefinite, ascending: testa coriaceous, smooth. Embryo straight, in the axis of a fleshy albumen: radicle pointing to the hilum.—Leaves opposite, entire, exstipulate. Flowers solitary, yellow.—Ex. *Columella*, *Menodora*.

A very little known order, lately established, and imperfectly characterised. Thus, Don says of *Menodora*, that the ovary is adherent (inferior), and the ovules indefinite; while Kunth, and Bonpland, who formed the genus, says the stamens are hypogynous, the ovary superior, and the ovules only two in each cell. The nearest affinity of this order is with Styracineæ, Jasminaceæ, and Ebenaceæ.

Order 108. *Symploceææ*. Juss.

Calyx monosepalous, limb entire or divided, persistent. Corolla perigynous or rarely hypogynous (?), monopetalous, regular: estivation imbricated or valvate. Stamens definite or indefinite, inserted into the tube of the corolla, unequal, mono- or polyadelphous at their base. Ovary cohering with the tube of the calyx either entirely or in part, or free, three, four, or five-celled: ovules four in each cell, of which two are ascending and two suspended: style simple: stigma simple: placentæ central. Fruit surrounded by or inclosed in the calyx, being a carcerulus, or a one- (by abortion) celled, three-valved, loculicidal, coriaceous capsule. Seeds usually solitary in the capsule, or in each cell of the carcerulus, erect or suspended: testa membranous or bony. Embryo straight, in the axis of a fleshy albumen: radicle pointing to the hilum: cotyledons

ange- flat, foliaceous.—Trees or shrubs. Leaves alternate, ex-
stipulate.—Ex. *Styrax*, *Symplocos*, *Ciponima*, *Halesia*.
Characters. In *Styrax* there is usually but one bony seed, but that
genus, although the corolla be certainly perigynous, is by
some referred with *Strigilia* to the Meliaceæ. Don asserts
that *Halesia* forms a very distinct group, so that the pre-
sent order would thus consist of *Symplocos*, to which
Kunth joins *Ciponima*, of which the characters are how-
ever still less understood than the other two. It may be
therefore considered as a dubious order, of which the
genera chiefly agree in the position of the ovules.—*Storax*
and benzoin are derived from the genus *Styrax*.

DIV. III.—*Dichlamydeæ Corollifloræ*. D. C.

(7. Hypocorollæ.¹ Juss.)

Order 109. *Ebenaceæ*. VENT.

Flowers uni- (rarely bi-) sexual. Calyx 3-6-divided,
nearly equal, persistent. Corolla monopetalous, regular,
deciduous, somewhat coriaceous, 3-6 divided: estivation
imbricated. Stamens inserted on the corolla, or hypogy-
nous, definite (two or four times as many as the segments
of the corolla, and rarely of the same number when they
alternate with them), filaments usually in two rows: an-
thers erect, linear-lanceolate, two-celled, bursting longitu-
dinally. Ovary free, sessile, plurilocular: ovules one
or two in each cell, pendulous: style divided, rarely sim-
ple: stigmas simple or bifid. Fruit fleshy, round or oval,
the pericarp sometimes opening regularly. Seeds few: testa
membranous. Embryo straight, nearly in the axis
of a cartilaginous albumen: radicle next the hilum: coty-
ledons foliaceous.—Trees or shrubs, without milky juice.
Leaves coriaceous, alternate, exstipulate.—Ex. *Diospyrus*,
Ferreola.

Allied to the Symplocæ, to the Sapotæ, and several
others that we have placed in the neighbourhood.—The
fruit is eatable, but the chief peculiarity of this order con-
sists in the extreme hardness of its wood. Ebony and
iron-wood both belong to it.

Order 110. *Ricineæ*. BRONGNIART.

Sepals 4-6: estivation imbricated. Corolla monopeta-
lous, hypogynous, 4-5-partite: estivation imbricated. Sta-
mens inserted into the base of the corolla, alternate with
its lobes, and equal to them in number: filaments straight:
anthers introrse. Torus not discoid. Ovary free, fleshy,
somewhat truncate, 2-6-celled: ovules solitary, pendulous
from a cup-shaped funiculus: stigma nearly sessile, lobed.
Fruit fleshy, indehiscent, containing from two to six one-
seeded nucules. Seed suspended. Embryo small, lying
at the end next the hilum of a large fleshy albumen: ra-
dicle superior: cotyledons small.—Trees or shrubs. Leaves
coriaceous, alternate, or opposite.—Ex. *Ilex*, *Prinos*.

Separated by Brongniart from the Celastrineæ. They
are much allied to the Ebenaceæ.—The leaves of some
species are used as tea. The bark and berries of others
are tonic, astringent, and antiseptic.

Order 111. *Sapotææ*. Juss.

Flowers bisexual. Calyx divided, regular, persistent.
Corolla hypogynous, deciduous, monopetalous, regular, its
lobes usually equal to, rarely twice or thrice as many as,
those of the calyx. Stamens inserted on the corolla, defi-
nite, distinct; the fertile ones as many as (rarely more than)
the segments of the calyx, with which they alternate; the
sterile ones between them rarely wanting. Ovary pluri-
locular: ovules solitary, erect: style one: stigma simple,
sometimes lobed. Fruit fleshy, plurilocular, or, by abor-

tion of the dissepiments, one-celled. Seeds solitary, erect: Arrange-
ment and Characters. testa bony, shining. Embryo large, erect, white, usually
inclosed in a fleshy albumen, which, however, is some-
times wanting: radicle short, straight, or slightly curved,
turned towards the hilum: cotyledons foliaceous (in the
albuminose seeds), or fleshy (in the exalbuminose seeds).
—Trees or shrubs, with copious milky juice. Leaves co-
riaceous, entire, alternate, exstipulate.—Ex. *Achras*, *Lu-
cuma*.

Closely allied to the Ebenaceæ, from which, however,
they differ by their having milky juice, bony seeds, bi-
sexual flowers, and various other important characters.—
The fruit of many, as the star-apple, the sappodilla plum,
and others, is much prized in their native countries. The
bark of some species of *Achras* is astringent and febrifugal.

Order 112. *Myrsineæ*. R. BROWN.

Flowers bisexual, rarely unisexual. Calyx 4-5-cleft,
persistent. Corolla monopetalous, hypogynous, 4-5-cleft,
equal. Stamens 4-5, inserted into the corolla, and oppo-
site its segments: filaments distinct, rarely connate, short,
sometimes wanting, with sometimes five sterile petaloid
alternating ones: anthers sagittate, erect, two-celled,
bursting longitudinally. Ovary free, one-celled: ovules
definite or indefinite, peltate, immersed in the placenta:
style one: stigma simple or lobed. Placenta free, central,
fleshy. Fruit fleshy. Seed usually solitary, sometimes
2-4, peltate: hilum concave: testa membranous, incorpo-
rated with the tegmen. Albumen horny. Embryo slen-
der, slightly curved, heterotropous (or lying across the
hilum): radicle horizontal when the seed is solitary, or
inferior when there are several seeds: cotyledons short.—
Trees or shrubs, rarely suffrutescent. Leaves coriaceous,
exstipulate, usually alternate.—Ex. *Myrsine*, *Ardisia*.

Allied to Sapotæ, but particularly to Primulaceæ in
the structure of the fruit, though with a very different
habit.—Bread is prepared from the pounded seeds of
Theophrasta Jussiei in St Domingo.

Order 113. *Jasminaceæ*.

Suborder 1. *Jasmineæ*. Juss. Flower bisexual. Calyx
divided or toothed, persistent. Corolla hypogynous, mono-
petalous, regular, hypocrateriform, 5-8-divided: estiva-
tion imbricated and twisted. Stamens two, inserted on
the corolla, inclosed within its tube: anthers two-celled,
bursting longitudinally. Ovary free, two-celled: ovules
solitary, rarely in pairs, at first pendulous, afterwards erect:
style one: stigma two-lobed. Fruit a double berry, or
pyxidium, or a bivalved capsule. Seeds usually solitary,
rarely in pairs, erect. Albumen none, or very thin. Em-
bryo straight: radicle inferior.—Shrubs, with usually twin-
ing stems. Leaves opposite, pinnate.—Ex. *Jasminum*, *Bo-
livaria*.

Suborder 2. *Oleineæ*. HOFFM. and LINK. Flowers
bisexual, or sometimes unisexual. Calyx gamosepalous,
divided, persistent. Corolla hypogynous, gamopetalous,
and four-cleft, sometimes of four petals, connected in
pairs by the intervention of the filaments, rarely wanting:
estivation somewhat valvate. Stamens two, alternate
with the segments of the corolla: anthers two-celled,
bursting longitudinally. Ovary free, two-celled: ovules
in pairs, collateral, pendulous: style one or none: stig-
ma entire or bifid. Fruit drupaceous, baccate, or capsu-
lar. Seeds often by abortion solitary. Albumen dense,
fleshy, abundant. Embryo straight, about half the length
of the albumen: radicle superior: cotyledons foliaceous.—
Trees or shrubs. Leaves opposite.—Ex. *Olea*, *Ligustrum*,
Fraxinus.

¹ Such orders as Brunoniaceæ, &c. which have the insertion of the corolla doubtfully hypogynous, but the stamens free from it, we,
with De Candolle, have referred to the Peripetalæ. Plumbaginæ, however, we have retained.

These two suborders are so very much allied that few separate them. *Bolivaria* has two seeds in each cell, and thus partakes of the character of both. In both the radicle points to the hilum. Their affinities extend on the one side to the Ebenaceæ and Columelliaceæ, and on the other to the Verbenaceæ.—The flowers are usually fragrant. The bark of the olive and ash is astringent and highly febrifuge. Olive oil is expressed from the pericarp, the oil of Jasmine from the flowers.

Order 114. *Asclepiadeæ*. R. BROWN.

Calyx five-divided, persistent. Corolla hypogynous, gamopetalous, regular, five-lobed, deciduous: estivation contorted-imbricate: rarely valvate. Stamens five, inserted into the base of the corolla, and alternate with its segments: filaments usually connate: anthers two-celled, each cell sometimes divided by incomplete septa: pollen, when the anther bursts, coalescing into masses which are as numerous as the cells, or sometimes confluent by pairs, and sticking to the five processes of the stigma, either by twos, by fours, or singly. Ovaria two: ovules indefinite: styles two, close to each other, often very short: stigma one, common to both styles, dilated, with five corpusculiferous angles. Placentas at the ventral sutures. Follicles two (sometimes one by abortion). Seeds indefinite, imbricate, pendulous, usually with a coma at the hilum. Albumen thin. Embryo straight: radicle superior: cotyledons foliaceous.—Plants, with usually a milky juice, often twining. Leaves entire, usually opposite, with interpetiolar ciliæ instead of stipules.—Ex. *Asclepias*, *Stapelia*.

Separated by Mr Brown from the Apocynæ on account of the very remarkable structure of the anthers and stigma.—The milky juice is usually acrid and bitter, and must always be regarded with suspicion, even although it seems in some few species to be used as aliment. The roots are generally acrid and stimulating; some few are diaphoretic and sudorific. The root and bark of the mudar plant (*Calotropis Mudara*), is a powerful purgative and alterative; and an extract, a new principle, called *mudarinc*, has the singular property of diliquescing by cold and congealing by heat.

Order 115. *Apocynææ*. JUSS.

Calyx five- rarely four-divided, persistent. Corolla hypogynous, gamopetalous, regular, five- rarely four-lobed, deciduous: estivation contorted-imbricate, rarely valvate. Stamens five, rarely four, inserted on the corolla, alternate with its lobes: filaments distinct: anthers two-celled, bursting longitudinally: pollen granular, globose, or three-lobed, immediately applied to the stigma. Ovaria two and each one-celled, or one and bilocular: ovules usually indefinite, rarely solitary or few: styles two or one: stigma one. Fruit follicular, or capsular, or baccate, or drupaceous, double or single. Seeds indefinite or rarely definite: albumen fleshy, cartilaginous, or horny, rarely wanting. Embryo foliaceous: radicle pointing to the hilum.—Plants, with usually a milky juice. Leaves entire, generally opposite, without stipules, but with interpetiolar ciliæ or glands.—Ex. *Apocynum*, *Vinca*, *Strychnos*.

We have now entered upon a group to be distinguished with great difficulty, so much do the orders run into each other; and indeed more than one botanist have suggested that the Rubiaceæ, Apocynææ, Loganiaceæ, and Gentianeæ, may form one class. Gentianeæ, however, touches upon Scrophularineæ, and this again on various others, so that we scarcely know what limits to impose on the series. *Strychnos*, *Carissa*, and some others, have been separated by Jussieu as a distinct order, having a simple fruit, and peltate seeds without a coma. To this, perhaps, *Gardnera* belongs, having a quaternary divided flower, valvate corolla, like *Strychnos*, simple fruit, and ecomose seeds. But then, some still referable to Apocynææ have a simple fruit

and comose seeds, others a double fruit and ecomose seeds, all of which might as well be made orders; besides, we doubt if, by having only one stigma, the ovarium ought to be ever considered as different from a syncarpous one.—The milk seems still more deleterious than that of the last order, being known to be used as food in only two plants. The root of some is poisonous, in others cathartic; in some the bark has these properties, in others the fruit. One seed of the Tanghin tree of Madagascar is sufficient to poison twenty persons. The nux-vomica is prepared from the seeds of the *Strychnos*. Of some species the bark is febrifugal.

Order 116. *Loganiaceæ*. R. BROWN.

Suborder 1. *Loganieæ*. Calyx quinque-partite. Corolla hypogynous, regular, or irregular: estivation convolute. Stamens inserted on the corolla, five or one (and therefore not corresponding with the divisions of the corolla): anthers bilocular, bursting longitudinally: pollen marked by three bands (MARTIUS). Ovarium free, two-celled: ovules indefinite: style continuous: stigma simple. Fruit either a two-celled capsule, with placentæ finally becoming loose; or a nuculanum with one or two-seeded nucules. Seeds peltate: testa finely reticulated, sometimes winged. Albumen fleshy or cartilaginous. Radicle turned towards the hilum.—Leaves entire, opposite, usually with interpetiolar sheathing stipules.—Ex. *Logania*, *Gartneria*.

Suborder 2. *Potalieæ*. MARTIUS. Calyx 4-5-6-partite. Corolla hypogynous, regular, 5-10-divided (not corresponding with the segments of the calyx): estivation contorted-convolute. Stamens inserted on the corolla: pollen elliptical, simple. Ovarium free: style continuous: stigma simple. Placentæ central, four-lobed. Fruit succulent, two- (or spuriously four-) celled. Seeds indefinite, peltate: testa and tegmen distinct. Albumen cartilaginous. Embryo heterotropous (MART.).—Trees or shrubs. Leaves entire, opposite, with interpetiolar sheathing stipules.—Ex. *Potalia*, *Fagraea*.

Suborder 3. *Spigeliææ*. MARTIUS. Calyx quinque-partite, regular. Corolla hypogynous, five-lobed: estivation valvate. Stamens five, inserted into the corolla: pollen triangular, the angles globular. Ovarium free, two-celled: ovules few: style articulated with the ovarium: stigma simple. Fruit capsular, two-celled, two-valved, septicidal, valves separating from the central placenta. Seeds few, nearly definite, small. Albumen copious, fleshy. Embryo very minute: radicle next the hilum.—Leaves entire, opposite, with stipules or a tendency to produce them.—Ex. *Spigelia*.

The genera of these three suborders have perhaps no very great affinity with each other. Some have been lopped off the Apocynææ, some taken from the Gentianeæ, others from the Rubiaceæ. All botanists now agree that they are osculating eccentric plants; and we have therefore brought them all here under the head of Loganiaceæ. Their general character lies in the free, two-celled ovary, and opposite stipulate leaves.—Their properties seem to be bitter, like the Gentians: some are acrid and emetic like the Apocynææ. The root of *Spigelia marilandica* is vermifuge, and in large doses cathartic.

Order 117. *Gentianeæ*. JUSS.

Calyx gamosepalous, usually 5- (sometimes 4-6-8 or 10-) divided, persistent. Corolla hypogynous, gamopetalous, usually regular, marcescent, or deciduous: limb divided into as many lobes as the calyx: estivation imbricate-twisted. Stamens inserted upon the corolla, alternate with the segments, and equal to them in number, some of them occasionally abortive: pollen three-lobed or triple. Ovarium single, of two carpels, the edges of which are either slightly inflexed, or meet in the axis, hence

Arrangement and Characters.

Arrangement and Characters.

1-2-celled: ovules indefinite: style one, continuous: stigmas one or two. Fruit capsular or fleshy, one-celled, usually two-valved, septicidal, or rarely (in *Menyanthes*) loculicidal. Seeds small, indefinite. Embryo straight, in the axis of a soft fleshy albumen: radicle next the hilum.—Leaves exstipulate, opposite, and entire (in *Menyanthes* and *Villarsia*, usually alternate, toothed, or divided).—Ex. *Gentiana*, *Chlora*.

From an examination of very imperfectly ripe fruit, we had concluded that the capsule of *Villarsia* was loculicidal, and thought ourselves confirmed by Brown, "Valvularum axibus seminiferis." But Gärtner and others assert the contrary: otherwise this character might serve to remove both *Menyanthes* and *Villarsia*, and form a distinct suborder. Martius says that the two carpels of the Gentianeæ are right and left, and not anterior and posterior; but certainly the one is (at all events where the quinary arrangement holds) opposite to the odd sepal, and the other to the odd petal, which again, with regard to the bractea, appear to us anterior and posterior. The torus presents a disc or gland in *Tachia* and *Villarsia*.—The Gentianeæ are intensely bitter; and this renders them, without exception, tonic, stomachic, and febrifugal.

Order 118. *Bignoniaceæ*. Juss.

Suborder 1. *Bignoniæ*. Calyx divided or entire, sometimes spathaceous. Corolla hypogynous, usually irregular, 4-5-lobed. Stamens five, unequal (one and sometimes three of them being sterile): anthers two-celled. Torus discoid. Ovarium superior, one or two-celled, each cell being often spuriously divided: ovules indefinite: style one: stigma bilamellate. Capsule one or two-celled, sometimes spuriously two or four-celled, two-valved. Seeds transverse, compressed, winged. Albumen none. Embryo straight, foliaceous: radicle next the hilum.—Trees or shrubs, or rarely herbaceous. Leaves opposite or rarely alternate, exstipulate.—Ex. *Bignonia*, *Spathodea*, *Eccremocarpus*.

Suborder 2. *Didymocarpeæ*.¹ Don. Calyx five-divided, equal. Corolla tubular, irregular, five-lobed, more or less bilabiate: estivation imbricate. Stamens four, didynamous (two sometimes sterile), rarely with the rudiment of a fifth: anthers two-celled, bursting longitudinally. Torus an annular disc. Ovarium superior, one-celled, of two carpels, the contiguous introflexed margins of which diverge, and form two or four spurious cells: ovules indefinite: style filiform: stigma two-lobed or bilamellate, or infundibuliform and entire. Fruit succulent, or capsular or siliquose, and two-valved. Seeds indefinite, small, ovate, or cylindrical, suspended, apterous, sometimes with a coma. Albumen none. Embryo straight: radicle next the hilum.—Usually herbaceous, sometimes shrubby plants. Leaves in general opposite, or radical.—Ex. *Didymocarpus*, *Cyrtandra*, *Fieldia*.

Suborder 3. *Pedalineæ*. R. BROWN. Calyx five-divided, nearly equal, rarely spathaceous. Corolla irregular, the tube ventricose, the limb five-lobed, bilabiate. Stamens four, didynamous (two sometimes sterile), with the rudiment of a fifth: anthers bilocular. Torus a glandular disc. Ovarium one or two-celled, of two carpels, the introflexed margins of which, by splitting and diverging, constitute several spurious cells: ovules few in each spurious cell: style one: stigma bilamellate or 2-4-cleft. Fruit drupaceous, or rarely capsular and two-valved, spuriously many-celled. Seeds few, large, apterous; pendulous, erect, or transverse. Albumen none. Embryo

straight, next the hilum.—Herbaceous plants. Leaves opposite.—Ex. *Pedaliium*, *Sesamum*.

Most botanists now agree that these three form but one order. The true *Incarvillea* has winged and perhaps transverse seeds, and belongs to Bignoneæ; while other species, by some united to it, have pendulous, apterous seeds, and belong to Didymocarpeæ. *Ramondia* is referred to Didymocarpeæ by Martius, but we know of none who has examined the mature seeds. If these be exalbuminose, then the character of the order may be slightly altered for its reception; in the mean time, on account of the anthers dehiscing by terminal pores, we refer it to the Solaneæ. *Bignonia* seems to have a one-celled fruit, with a transverse septum or projection from its parietal placentæ. *Arragoa* is too imperfectly known for any one to judge of its place. The Bignoniaceæ are nearly allied to Scrophularineæ and Solaneæ, but have no albumen.—Nothing almost is known of their medical properties.

Order 119. *Polemoniideæ*. Juss.

Suborder 1. *Cobææ*. Don. Calyx foliaceous, five-cleft, equal. Corolla campanulate, equal, limb five-lobed: estivation imbricate. Stamens five, equal, inserted on the base of the tube: anthers entire, two-celled. Torus large, discoid, five-angular. Ovarium free, simple, of three carpels, one-celled (spuriously three-celled, by means of the placentæ of each carpel being introflexed and attached to the sides of a solid triangular centre axis): ovules indefinite, ascending: style simple: stigma trifid. Capsule somewhat fleshy, spuriously three-celled, three-valved, septicidal: placentæ attached to the central axis, and separating from the valves. Seeds flat, winged, ascending, in a double row. Albumen thin, fleshy, soft. Embryo straight, large: radicle cylindrical, pointing to the hilum, inferior: cotyledons broad, compressed, cordate.—Climbing diffuse shrubs. Leaves alternate, pinnate, terminated by a tendril.—Ex. *Cobæa*.

Suborder 2. *Polemoniæ*. Juss. Calyx five-divided, persistent, sometimes irregular. Corolla regular, rarely irregular, five-lobed. Stamens five, inserted on the middle of the tube of the corolla, and alternate with its segments. Anthers entire. Torus discoid, lobed. Ovarium free, of three carpels, three-celled, or one-celled (and spuriously three-celled by the introflexed placentæ being united with a triangular central axis): ovules ascending: style simple: stigma trifid. Capsule three-celled, or spuriously so, three-valved, loculicidal: placentæ in the axis, and separating from the valves. Seeds few or numerous, angular or oval, often enveloped in mucus, ascending, in a single row. Embryo straight, in the axis of a horny albumen: radicle inferior, next the hilum; cotyledons elliptical, foliaceous.—Herbaceous, erect plants. Leaves opposite or alternate, simple or variously divided.—Ex. *Polemonium*, *Phlox*, *Bonplandia*.

This order borders very close on the Bignoniaceæ, especially *Cobæa*, in which genus, had the seeds been attached to the margins of the valves, and consequently the septa been merely projections of the placentæ, as in *Bignonia*, we should have referred it to that order, notwithstanding the trifid stigma, and the presence of some albumen. On the other side, Polemoniideæ are allied to Convolvulaceæ, but from this the shape of the embryo is sufficient to distinguish them.

Order 120. *Hydroleaceæ*. R. BROWN.

Calyx five-parted, persistent: estivation imbricated. Corolla regular, not always agreeing with the calyx in

¹ On account of its priority, we have adopted this name, instead of Cyrtandraceæ given to these plants by Dr Jack. Jack's paper was read in May 1822, and published long afterwards in the 14th volume of the *Linnean Transactions*; Don's was read on 26th January 1822, and published in July that same year.

Arrangement and Characters.

the number of its divisions: estivation plicate or imbricate. Stamens five, inserted on the corolla, equal: anthers deeply lobed at the base, two-celled. Torus an annular disc. Ovary free, 2-3-celled: ovules indefinite: styles two or three: stigmas incrassated. Fruit capsular, 2-3-celled, loculicidal. Seeds indefinite, very small. Embryo straight, in the axis of a fleshy albumen: radicle next the hilum: cotyledons flat.—Leaves alternate, exstipulate, often covered with glandular or stinging hairs.—Ex. *Hydrolea*, *Diapensia*.

Almost exactly intermediate between Polemoniaceæ and Convolvulaceæ; like the former, having the placenta often adhering to the axis and separating from the valves, and principally differing in the plurality of styles. From Convolvulaceæ the dehiscence of the capsule, the number of seeds, the albumen, and flat cotyledons, will distinguish them.

Order 121. *Convolvulaceæ*. Juss.

Calyx five-divided, persistent. Corolla deciduous, regular, five-lobed: estivation usually plicate. Stamens five, inserted on the base of the corolla, alternate with its segments. Torus discoid. Ovary free, of two, three, or four carpels, usually syncarpous, rarely apocarpous, usually with two, three, or four cells, rarely by abortion one-celled: ovules erect, definite; when more than one, collateral: style one, sometimes entire, usually bifid, rarely two: stigmas obtuse or acute. Capsule 1-4-celled, septifragal and septicidal; sometimes without valves, or a pyxidium. Seeds at the base of the placenta. Albumen mucilaginous. Embryo curved: radicle inferior: cotyledons corrugated, rarely inconspicuous.—Herbaceous plants or shrubs, usually twining and with a milky juice. Leaves alternate, exstipulate.—Ex. *Convolvulus*, *Falkia*, *Cuscuta*. (Plate CXIX.)

Cuscuta, from its having no leaves developed, has, as may be presumed, no conspicuous cotyledons. Analogy, however, enables us to assert that they do exist, although in an abortive state. In *Cuscuta* the calyx and corolla are sometimes four-lobed, the stamens four. *Dichondra* and *Falkia*, usually described as with apocarpous ovaria, ought rather, by analogy, to be considered as syncarpous, with a deeply-divided style.—An acrid, purgative, milky juice abounds in the roots: the Jalap and Scammony are obtained from those of species of *Convolvulus*. The roots of *C. batatas* (or sweet potato) and *C. edulis* are eaten.

Order 122. *Cordiaceæ*. R. BROWN.

Calyx five- (rarely four-) toothed. Corolla with the limb 5-4- (rarely 10-) cleft. Stamens inserted on the corolla, alternate with its segments: anthers versatile. Ovary free, four-celled: ovule solitary: style continuous: stigma four-cleft. Fruit with a fleshy epicarp; sarcocarp bony, four-celled (some of them occasionally abortive). Seed erect, attached to a long funiculus that proceeds from the apex of the cell to the base. Albumen none. Radicle superior: cotyledons plaited longitudinally.—Trees. Leaves alternate, scabrous, exstipulate. Flowers paniced.—Ex. *Cordia*, *Varronia*.

Perhaps not distinct from Boraginaceæ, but somewhat allied to Convolvulaceæ by the plaited cotyledons.—The flesh of the fruit is mucilaginous and emollient. The *Sebesten* plums are produced by *Cordia Myxa* and *C. Sebestena*.

Order 123. *Boraginaceæ*. Juss.

Suborder 1. *Ehretieæ*. MART. Calyx five-parted: estivation imbricate. Corolla tubular, limb five-divided: estivation imbricated. Stamens five, inserted on the base of the corolla, alternate with its segments: anthers erect. Torus an annular disc. Ovary free, simple, two or four celled: ovules four, suspended: style terminal: stigma simple, two-lobed. Fruit a nuculanum. Seeds four, sus-

ended, some occasionally abortive. Albumen very thin and fleshy, or wanting. Embryo straight or curved: radicle next the hilum: cotyledons plano-convex.—Trees or shrubs. Leaves alternate, scabrous, or harshly pubescent, exstipulate. Flowers in corymbose spikes, or panicles.—Ex. *Ehretia*, *Tournefortia*.

Suborder 2. *Heliotropiceæ*. MART. Calyx five-parted, persistent. Corolla regular, five-lobed: estivation imbricate. Stamens inserted on the tube of the corolla, alternate with its segments: anthers erect. Torus discoid. Ovary free, entire, or two-lobed, four-celled: ovules four, pendulous: style terminal or between the lobes, simple: stigma simple or bifid. Fruit dry, separable into four achenia. Seed pendulous, solitary. Albumen none, or very thin and fleshy. Radicle minute, next the hilum, superior: cotyledons fleshy, plano-convex, or convolute.—Somewhat shrubby or herbaceous plants. Leaves alternate, scabrous, exstipulate. Flowers in terminal, fasciculated or corymbose spikes.—Ex. *Heliotropium*, *Tiaridium*, *Coldenia*.

Suborder 3. *Borageæ*. Calyx five-divided, persistent. Corolla regular, five-cleft: estivation imbricate. Stamens inserted on the corolla, alternate with its segments: anthers erect. Ovary four-lobed, four-celled: ovules four, each suspended from the inner angle and near the summit of the cell: style simple, arising from the base of the lobes of the ovary: stigma simple or bifid. Fruit a microbasis, separable into four achenium-like, or two bilocular bony, portions. Seed suspended. Albumen none. Radicle superior, short: cotyledons plano-convex.—Herbaceous plants or shrubs: stem terete. Leaves alternate, scabrous, exstipulate. Flowers usually spicate.—Ex. *Borago*, *Myosotis*.

There is scarcely any good character between these. The first may be best distinguished by its fleshy fruit, the last by the fruit being a microbase, and the second by the fruit being dry and yet not a microbase. In the *Borageæ*, as may be easily seen in *Cerithe*, a placenta, or rather a conducting thread, passes up through the sarcocarp at the inner angle of each part of the fruit, and enters the cell between the middle and the summit, bearing the seeds, which are thus suspended, not erect as some botanists say. In *Tiaridium* the fruit has two divaricating lobes, between which the style is inserted: a cord passes from its base along the middle of each lobe, to near the apex, where it enters each cell, forming a double placenta. *Coldenia* seems to have a thin albumen, and somewhat convolute cotyledons. The *Ehretieæ*, on account of the fleshy fruit, formed part of the original family of *Sebesteniæ* (*Cordiaceæ*) of Ventenat. Although we have termed the fruit in all these four-celled, it, however, consists only of two cells, each of which is divided into two by an incrassation and inflexion of the dorsal nerve. A fifth part is sometimes suppressed from the calyx, corolla, and stamens.—The *Borageæ* are mucilaginous and emollient. Some contain nitrate of potash, which gives a coolness to the beverage in which their leaves are steeped. The roots of others give out a reddish brown dye.

Order 124. *Hydrophyllææ*. R. BROWN.

Calyx five- or ten-divided, persistent. Corolla regular or nearly so, five-lobed, with two lamellæ towards the base of each constituent petal. Stamens alternate with the lobes of the corolla: anthers ovate, two-celled, versatile, bursting longitudinally. Ovary free, simple, one-celled: ovules definite or indefinite, suspended: style terminal, bifid: stigmas two. Placenta two, parietal, or on stalks from the base of the cavity. Fruit capsular, one-celled, two-valved, loculicide. Seeds definite or indefinite. Embryo small at the umbilical extremity of a copious cartilaginous albumen: radicle superior.—Herbaceous his-

Arrangement and Characters.

pid plants. Leaves opposite, or alternate and lobed.—

Ex. *Hydrophyllum*, *Phacelia*.

Closely allied to Boraginæ, from which Mr Brown separated them in the *Prodromus Floræ Nov. Holl.*, and in the appendix to Franklin's *Overland Expedition*. What are termed here stalked placenta, are, we suspect, the parietal placenta detached from the back of each valve, but remaining attached to the base of the cell.

Order 125. *Solanæ*. Juss.

Calyx five- (rarely four-) parted, persistent. Corolla with the limb five- (rarely four-) cleft, regular, or somewhat unequal, deciduous: estivation plicate, or in some imbricate. Stamens inserted on the corolla, alternate with its segments, sometimes one abortive: anthers bursting longitudinally or by terminal pores. Ovarium two or more celled, rarely one-celled: ovules usually indefinite: style continuous: stigma obtuse, rarely lobed. Fruit either a capsule, which is 2-4-celled, 2-4-valved, and septicidal, or opening transversely with a double dissepiment; rarely one-celled, two-valved, the margins introflexed, and bearing the placenta; or a 2-4-celled berry, with the placenta adhering to the dissepiment; or a nuculanum, with five or more nucules which have spurious one or more cells with one seed in each. Seeds sessile. Embryo more or less curved, often eccentric, lying in a fleshy albumen: radicle next the hilum.—Herbaceous plants or shrubs. Leaves alternate.—Ex. *Solanum*, *Nicotiana*; *Nolana*; *Verbascum*, *Anthocercis*.

Allied to both Convolvulaceæ and Boraginæ, with which last, and also with Hydrophyllæ, it has sometimes been proposed to associate *Nolana*: this genus, indeed, merits being made into a suborder. As to *Verbascum*, *Ramondia*, *Celsia*, *Anthocercis*, and *Duboisia*, they have the habit of the Solanæ, but the imbricate corolla, unequal stamens, and almost straight embryo, of the Scrophularinæ; and if they are not conjoined with these, and the character of the present order thus made more rigorous, we cannot point out a decided distinguishing character between the two families. *Ramondia* has a unilocular fruit. *Triguera* seems to have an irregular, plicate corolla, and the fruit a tetrachenium; but this genus is little known.—Upon the whole, the leaves of the Solanæ are narcotic and acrid: those of *Verbascum*, however, and probably of the others with an imbricate corolla, are mucilaginous. The roots are usually poisonous. The fruit is also in general very poisonous, although, whether by the effects of cultivation, or some peculiarity in the plants themselves, that of the Love-apple, Tomato, Capsicum, and a few others, are eaten without inconvenience. The tubers formed on the potato-plant are, when boiled, highly alimentary. The dominant property of these vegetables is their stupifying action, which is usually joined to an acrid principle. The *νυκτερινός* of Homer (*Od.* iv. l. 221), supposed by some to be the poppy, seems rather to be the *Hyoscyamus*, which has still a similar name applied to it in some eastern languages.

Order 126. *Orobanchæ*. VENT.

Calyx divided, persistent. Corolla irregular, usually bilabiate, persistent: estivation imbricated. Stamens four, didynamous. Torus a fleshy disc. Ovarium free, one-celled, of two carpels, whose edges are sometimes slightly introflexed and divaricated: ovules indefinite: style one: stigma two-lobed. Fruit capsular, inclosed within the withered corolla, one-celled, loculicide. Seeds indefinite, minute. Embryo very minute, lodged in a lateral hollow near the apex of a fleshy albumen.—Herbaceous, leafless, parasitical plants.—Ex. *Orobanche*, *Lathræa*.

Richard, and Nuttall (under his genus *Epiphagus*), describe the embryo situated as above: Gærtner, how-

ever, figures it in *Lathræa* at the base of the albumen; but the character is too minute to be of much use. This order approaches very close to the following, from which, however, it is easily distinguished; and also to the Gesneriaceæ.—*Orobanche major* is powerfully astringent.

Order 127. *Scrophularinæ*. Juss.

Calyx divided, unequal, persistent. Corolla usually irregular and bilabiate or personate, deciduous: estivation imbricate. Stamens usually four, didynamous, rarely equal, sometimes two. Torus discoid. Ovarium free, two-celled: ovules definite or indefinite: style simple: stigma two-lobed, rarely entire. Fruit capsular (rarely fleshy), two-celled (rarely, by the obliteration of the dissepiments, one-celled), 2-4-valved, loculicidal or septicidal: dissepiment distinctly double, or apparently single. Placenta central in maturity, either remaining attached to the dissepiment, or becoming loose. Seeds definite or indefinite. Embryo straight, included within a fleshy albumen.—Herbaceous, seldom shrubby, plants. Leaves usually opposite.—Ex. *Veronica*, *Erimus*, *Scrophularia*, *Rhinanthus*, *Melampyrum*.

After Brown, we unite the Pediculares of Jussieu to the Scrophularinæ, the two kinds of dehiscence of the capsule being found sometimes in the same genus. Richard, in 1828, proposed to make use of another character, viz. the direction of the embryo, which he supposes to be orthotropous in the true Scrophularinæ, and heterotropous or inverted in the Pediculares or Rhinanthaceæ. Mr Lindley has therefore lately availed himself of this structure. But the only genera we can discover with a heterotropous embryo are, *Rhinanthus*, *Melampyrum*, and *Pedicularis*; *Euphrasia* and *Bartsia*, so allied to them, having it orthotropous. In the above three the embryo is minute, while in all the others it occupies a great part of the length of the albumen.—This family presents no great uniformity in its properties; the greater number, nevertheless, containing a principle more or less acrid, purgative in *Gratiola* and some *Scrophulariæ*, but so powerful in *Digitalis purpurea* (the fox-glove), that this plant is very poisonous unless in small doses. *Euphrasia* is slightly astringent and aromatic, without the deleterious qualities of the other genera.

Order 128. *Labiata*. Juss.

Calyx tubular, regular, or bilabiate, persistent. Corolla bilabiate; upper lip entire or bifid, lower three-cleft: the upper in estivation overlapping the lower. Stamens four, didynamous (two being sometimes abortive), inserted on the corolla, alternate with the lobes of the lower lip: anthers two-celled, sometimes apparently one-celled, either by the obliteration of the septum, or by the abortion of a cell. Ovarium free, deeply four-lobed: ovules four: style one, proceeding from the base of the lobes: stigma bifid, usually acute, sometimes unequal or dilated. Fruit a microbasis, separable into four achenia. Seeds erect, some of them occasionally abortive. Albumen none, or very thin. Radicle inferior: cotyledons flat.—Herbaceous or suffrutescent plants, with quadrangular stems. Leaves opposite, exstipulate.—Ex. *Salvia*, *Teucrium*, *Scutellaria*.

The Labiata approach to the Boraginæ, and also to the Verbenaceæ. The leaves are full of little utricles of oil.—Two principles are found in these plants; the one aromatic and stimulant owing to the abundance of the essential oil, the other bitter; and, according as the one or the other predominates, so they are cordial, sudorific, and antispasmodic, or tonic and stomachic. The order contains no dangerous plants.

Order 129. *Verbenaceæ*. Juss.

Suborder 1. *Myoporinæ*. R. BROWN. Calyx five-parted, persistent. Corolla nearly equal, or bilabiate. Stamens four, didynamous, with the rudiment of a fifth some-

Arrangement and Characters.

Arrangement and Characters. times bearing pollen. Torus an annular disc. Ovary free, 2-4-celled: ovules four, pendulous: style one: stigma scarcely divided. Fruit an osteocarpium, with a fleshy epicarp and bony sarcocarp, with 2-4-cells: seeds four. Embryo cylindrical, in the axis of a firm albumen: radicle superior.—Shrubs. Leaves alternate or opposite, exstipulate.—Ex. *Myoporum*, *Bontia*.

Suborder 2. *Verbenææ*. Calyx tubular, persistent. Corolla tubular, deciduous, limb usually irregular. Stamens four, didynamous, rarely equal, sometimes only two. Ovary free, 2-4-celled: ovules four, erect, rarely pendulous, and then becoming erect after fecundation: style one: stigma bifid or entire. Fruit an osteocarpium, or nuculanum, or a tetrachenium (the epicarp being sometimes extremely thin). Seeds erect, four, or by abortion three or one. Albumen none, or very thin. Embryo straight: radicle inferior.—Trees or shrubs, rarely herbaceous plants. Leaves usually opposite, exstipulate.—Ex. *Verbena*, *Vitex*, *Avicennia*.

Suborder 3. *Selaginææ*. Juss. Calyx tubular, rarely of two sepals, persistent. Corolla tubular; limb five-lobed, irregular. Stamens four, usually didynamous, seldom only two, inserted on the top of the tube of the corolla: anthers one-celled. Ovary free, very minute: style one, filiform. Fruit membranous, two-celled, one cell often abortive. Seed solitary in each cell, erect. Embryo in the axis of a fleshy albumen: radicle superior, at the opposite extremity from the hilum.—Herbaceous or shrubby plants. Leaves alternate, exstipulate.—Ex. *Selago*, *Hebenstreitia*.

These have a somewhat similar habit, and only differ from each other by very minute characters. Through *Verbena* they are allied to the last order; and through *Selaginææ* to both *Scrophularinææ* and *Acanthaceææ*.—Their properties are of little importance; the Vervein has long since fallen into disrepute; and the fruit of the *Vitex Agnus-castus*, being hot and aromatic, may be expected to produce a contrary effect from that from which the plant derived its name. The bark of *Avicennia tomentosa* is used in Brazil for tanning. The Teak-tree of East India belongs to this family.

Order 130. *Acanthaceææ*. Juss.

Calyx 5-4-divided, equal or unequal, rarely either multifid or entire and obsolete, persistent. Corolla mostly irregular, with the limb ringent or bilabiate, or occasionally with one lip, sometimes nearly equal, deciduous. Stamens mostly two, sometimes with other two or three shorter ones, two of which are sometimes fertile: anthers either two-celled or one-celled, bursting longitudinally. Torus a glandular disc. Ovary free, two-celled: ovules two or many in each cell: style one: stigma two-lobed or entire. Placentæ in the axis. Capsule two-celled, elastically two-valved, loculicidal. Seeds two or many in each cell, sometimes by abortion solitary, ascending, usually subtended by rigid subulate persistent ascending processes from the placentæ: testa loose. Albumen none. Embryo curved or straight: radicle cylindrical, descending, next the hilum: cotyledons large, foliaceous.—Herbaceous plants or shrubs. Leaves opposite, exstipulate. Flowers with three (or by abortion two) bractæas to each.—Ex. *Acanthus*, *Justicia*.

The flowers, as in *Thunbergia*, have sometimes large bractææ inclosing an obsolete calyx. They approach the *Scrophularinææ* in habit, and *Bignoniaceææ* in character, from which it is extremely difficult to separate those genera that want the hooked processes of the placentæ.—*Acanthus mollis* is considered emollient. The properties of the other genera of this order are almost unknown.

Order 131. *Lentibulariææ*. RICHARD.

Calyx divided, persistent. Corolla irregular, bilabiate,

with a spur. Stamens two, included within the corolla, arranged and inserted into its base: anthers one-celled, sometimes contracted in the middle. Ovary free, of two carpels, one-celled: ovules indefinite: style one, very short: stigma unequally bilamellate. Placentæ central, erect, globular. Fruit capsular, one-celled, opening transversely, or by a longitudinal cleft at the apex. Seeds minute. Albumen none. Embryo with two (sometimes inconspicuous) cotyledons.—Herbaceous, marsh or water plants, or parasites. Leaves radical, often abortive. Flowers on scapes.—Ex. *Pinguicula*, *Utricularia*.

These are most closely allied to the *Scrophularinææ*, from which they are distinguished by the ovary being one-celled, or, in other words, by the inflexed part of the carpellary leaves being at an early age obliterated. The large, central, free placenta allies them to the *Primulaceææ*; but these have more than two carpellary leaves and a copious albumen.

Order 132. *Primulaceææ*. Juss.

Calyx five- (rarely four-) cleft, regular, persistent. Corolla hypogynous, rarely perigynous, with the limb regular, five- (rarely four-) cleft, rarely wanting. Stamens inserted upon the corolla or hypogynous, equal in number, and opposite to its segments. Ovary free (rarely with its base adherent to the calyx), one-celled, of five (rarely four) carpels: ovules indefinite: style one: stigma capitate. Placentæ central, free. Capsule opening by valves, or a pyxidium. Seeds numerous, peltate. Embryo straight, cylindrical, inclosed within a fleshy albumen, transverse, or rarely in the axis.—Herbaceous plants. Leaves usually opposite.—Ex. *Primula*, *Trientalis*.

Closely allied through the last order to *Scrophularinææ* and the other *Hypocorollææ*; to *Myrsinææ* however it has the greatest affinity, from which it is best known by its capsular and not fleshy fruit. *Samolus* has the ovary only partly free, and has five sterile stamens alternate with the fertile ones, but cannot be confounded with any of the *Pericorollææ* if we consider the structure of the fruit and seed. *Glaux* has no petals, but the stamens are still alternate with the sepals; Don has united it with the *Plantaginæææ* on account of the embryo being in the axis of the albumen; but the stamens are erect in estivation, and the fruit one-celled.—The Cowslip is slightly narcotic, and the root of the *Cyclamen* acrid; but little is known about their properties.

Order 133. *Globularinæææ*. D. C.

Calyx five-cleft, usually equal, sometimes bilabiate, persistent. Corolla tubular, five-parted, bilabiate, or rarely of one lip. Stamens four, somewhat didynamous, inserted into the top of the tube of the corolla, alternate with the segments of the lower lip: anthers reniform, one-celled. Ovary free, one-celled: ovule solitary, pendulous: style filiform, persistent: stigma bifid. Fruit indehiscent. Seed pendulous. Embryo straight, in the axis of a fleshy albumen: radicle superior.—Shrubby or herbaceous plants, with perennial roots. Leaves alternate. Flowers capitate, on a paleaceous bracteated receptacle.—Ex. *Globularia*.

Jussieu and De Candolle considered this allied to the *Primulaceææ*. Cambessedes has lately demonstrated their affinity with the *Verbenaceææ* (*Selaginæææ*), and more particularly with the *Dipsaceæææ*. Perhaps they ought to be placed in the vicinity of the *Brunoniaceæææ* and *Goodenoviææææ*, with which last they agree in the irregular corolla: but in the *Dipsaceææææ* and these two the torus surrounds the ovary, and either appears on its surface in the shape of a disc, or incloses the style and forms a cup under the stigma, whereas here it is almost imperceptible at the bottom of the calyx.—Bitter, tonic, and purgative.

Order 134. *Plumbaginææææ*. Juss.

Calyx tubular, persistent: estivation plicate: corolla

gamopetalous, or of five distinct petals, regular. Stamens five, hypogynous when the petals are combined, inserted into the base of the petals when distinct. Ovarium free, one-celled: ovule solitary, pendulous from the extremity of an umbilical cord arising from the bottom of the cell: styles five, seldom three or four, each bearing a subulate stigma. Fruit a utricle. Seed pendulous: testa and tegmen combined. Embryo straight, in the axis of a farinaceous albumen: radicle superior.—Herbaceous or suffrutescent plants. Leaves alternate or fasciated, somewhat sheathing at the base. Flowers panicled, either loosely or in a capitate manner.—Ex. *Plumbago*, *Statice*, *Armeria*.

Jussieu and De Candolle consider the calyx as a kind of involucre, and the petals as a perianth, probably on account of other points of resemblance between this order and Nyctagineæ, in which there is no corolla.—The genus *Plumbago* is caustic and acrid. *Statice* is tonic and astringent.

Order 135. *Plantagineæ*. Juss.

Sepals four (rarely three), somewhat unequal, persistent: estivation imbricate. Corolla tubular, with a four- (rarely three-) parted limb, scarious, persistent. Stamens four, inserted into the tube of the corolla, or its base, alternate with its segments: filaments long, filiform, doubled inwards before fecundation: anthers versatile, two-celled. Torus inconspicuous. Ovarium free, two- seldom four- and very rarely one-celled: ovules solitary, in pairs, or indefinite: style simple capillary: stigma hispid, simple or rarely bifid. Fruit a pyxidium, inclosed within the persistent corolla. Seeds sessile, peltate or erect: testa mucilaginous. Embryo in the axis of a fleshy albumen: radicle inferior.—Herbaceous and generally stemless plants. Flowers bisexual in spikes, or unisexual and solitary, the male on a long peduncle, the female sessile.—Ex. *Plantago*, *Littorella*.

We agree with Brown and some others, that this has a true calyx. In the genus *Plantago*, the filaments, although only freed from the corolla in their upper part, really have the same origin as the corolla, but are adnate to its tube.—The Plantains are bitter, astringent, and slightly febrifugal.

Div. IV.—*Monochlamydeæ*. D. C.

(8. Hypostamineæ. Juss.)

Order 136. *Nyctagineæ*. Juss.

Perianth tubular, coloured, contracted in the middle, becoming indurated at the base; limb entire or toothed: estivation plicate. Stamens definite, hypogynous: anthers two-celled. Torus a glandular disc. Ovarium free, one-celled: ovule solitary erect: style one; stigma one. Fruit a caryopsis, inclosed within the enlarged persistent tube of the perianth. Embryo rolled round a farinaceous albumen: radicle inferior: cotyledons foliaceous.—Leaves opposite, rarely alternate. Flowers with an involucre, which is either common or proper, one or many-leaved, or sometimes minute.—Ex. *Mirabilis*, *Boerhaavia*.

The nearest affinity of this order is with Plumbagineæ, but particularly with Polygoneæ: it is, however, very distinct from either. The genus *Mirabilis*, that word being an adjective, ought to be called *Nyctago*.—The root of the Marvel of Peru, and most others of this family, is purgative.

Order 137. *Amaranthaceæ*. Juss.

Perianth 3-5-partite, scarious, persistent, with usually two bracteoles at the base. Stamens as numerous as the segments of the perianth, distinct, or united into a membranous cup or tube, occasionally partly abortive, often with intermediate barren filaments or processes: anthers two-celled or one-celled. Ovarium single, free, one-celled: ovules solitary or several, suspended from a free cen-

tral funiculus: style one or none. Stigma simple or compound. Fruit an utricle or a pyxidium, rarely a berry. Seeds lentiform, pendulous: testa crustaceous. Embryo curved round a central farinaceous albumen: radicle near the hilum.—Herbaceous plants or shrubs. Leaves opposite or alternate, exstipulate. Flowers capitate or in spikes, usually bisexual.—Ex. *Amaranthus*, *Gomphrena*, *Deeringia*.

Closely allied in many respects to the Illecebreæ: nor is it easy to point out any general distinguishing character. Martius supposes the bracteoles to be a true calyx, and the perianth a corolla.—The leaves are mucilaginous. This order is chiefly cultivated for its showy flowers.

Div. IV.—*Monochlamydeæ*. D. C.

(9. Peristamineæ. Juss.)

9. Peristamineæ.

Order 138. *Chenopodeæ*. D. C.

Perianth ebracteate, deeply divided, sometimes tubular at the base, persistent: estivation imbricate. Stamens inserted into the base of the perianth, or sometimes hypogynous opposite its segments, and equal to them in number, occasionally fewer. Ovarium single, free, or sometimes cohering with the tube of the perianth, one-celled: ovule solitary, attached to the base of the cell: style 2-4-divided: stigmas simple. Fruit indehiscent, membranous, inclosed in the calyx, which becomes often enlarged or fleshy. Seed erect or resupinate. Embryo curved, placed round a farinaceous albumen, or spiral, or doubled together without albumen: radicle next the hilum.—Leaves alternate, sometimes opposite, exstipulate. Flowers bi- or unisexual.—Ex. *Chenopodium*, *Atriplex*.

Very difficult to be distinguished by a character from the last order, although usually with a habit very different.—Some, as the Spinage, are used as pot-herbs: of others, the root, as of the Beet, is eaten.—Many possess an essential oil. The *Salsola*, *Salicornia*, and others, yield much soda.

Order 139. *Phytolaccaceæ*. R. BROWN.

Suborder 1. *Phytolaccæ*. Perianth 2-4-5-partite. Stamens inserted into the base of the perianth, indefinite, or as few as the segments of the perianth, alternate with them. Ovarium of one or several carpels, syncarpous or apocarpous: ovule one in each carpel, ascending: styles equal to the number of the carpels, terminal in the simple ovary, lateral in the apocarpous: stigmas simple or divided. Fruit baccate or dry, indehiscent. Seeds solitary, ascending. Embryo curved round a mealy (rarely a fleshy) albumen: radicle next the hilum.—Leaves alternate, exstipulate, often with pellucid dots.—Ex. *Phytolacca*, *Rivina*, *Giskia*, *Theligonum*.

Suborder 2. *Petiveriæ*. Ag. Perianth 4-5-partite. Stamens perigynous, indefinite; or, if occasionally equal in number to the leaves of the perianth, alternate with them. Ovarium one, free, one-celled: ovule solitary, erect: style one, lateral: stigma simple or penicillate. Fruit dry, one-celled, indehiscent. Seed erect. Albumen 0. Embryo straight: radicle inferior: cotyledons convolute.—Leaves alternate, often dotted, with minute deciduous stipules (in *Petiveria*).—Ex. *Petiveria*, *Sequiera*.

We do not see why these ought to be separated; their habit is precisely the same. *Microtea* and *Ancistrocarpus*, both with albumen, approach closely to *Petiveria* by the prickles on the fruit. *Rivina* also exhibits a tendency to have the cotyledons convolute. We have joined to them *Theligonum*, although with an oily and somewhat fleshy albumen. De Candolle and Richard do not separate this family from Chenopodeæ.—*Phytolacca decandra* is a purgative: its root is emetic, as also is a spirit distilled from its berries: but a tincture from them seems to be much

esteemed for chronic rheumatism. The leaves are acrid; but young shoots, when boiled, are used instead of asparagus.

Order 140. *Polygonææ*. Juss.

Suborder 1. *Persicariææ*. Flowers solitary. Perianth divided: estivation imbricate. Stamens definite, inserted into the bottom of the perianth: anthers bursting longitudinally. Ovary one, free: ovule solitary, erect: styles or stigmas several. Fruit a nut, naked, or covered by the enlarged perianth. Seed erect. Albumen farinaceous, rarely very thin and fleshy. Embryo usually on one side of the albumen: radicle superior.—Herbaceous, rarely shrubby plants. Leaves alternate, sheathing at the base, or adhering there to intrafoliaceous stipules, revolute when young. Flowers often unisexual.—Ex. *Polygonum*, *Rumex*.

Suborder 2. *Eriogonææ*. Flowers bisexual, collected in a campanulate involucre. Perianth campanulate, six-cleft: estivation imbricate. Stamens nine, inserted into the bottom of the perianth: anthers bursting longitudinally. Ovary one, free: ovule solitary, erect: stigmas three. Fruit an achenium, covered by the persistent perianth. Seed erect. Albumen farinaceous. Embryo straight, in the axis of the albumen: radicle superior, remote from the hilum.—Herbaceous plants. Leaves alternate, usually tomentose, neither sheathing nor with intrafoliaceous stipules.—Ex. *Eriogonum*.

The erect ovule and superior radicle will distinguish this at once from the two last orders. The second suborder contains, in addition to *Eriogonum*, an allied genus from South America, in which the segments of the involucre terminate in spiny processes, and the fruit is lenticular, although with a triangular beak.—In almost all the species the root and young leaves have an astringent and acid taste, the first owing to the presence of tannin and gallic acid, the second to oxalic acid, which makes them rank among tonic medicines. The roots of some, as the rhubarb, possess, in addition, a purgative property. The seeds of all, with the exception of those of *Polygonum hydropiper*, which are hot and acrid, may be used as food, like those of most other orders with a copious farinaceous albumen.

Order 141. *Begoniæææ*. R. BROWN.

Flowers unisexual. Perianth coloured; of four or sometimes 3-9 in the males, or 5-6 in the females, tepals or leaves, of which some are smaller than the others: estivation imbricate. Stamens indefinite, distinct, or united into a solid column: anthers collected in a head, continuous, clavate, two-celled, bursting longitudinally, with a very thick connectivum. Ovary coherent with the tube of the perianth, of three carpels, each with the dorsal nerve winged, three-celled: ovules indefinite: stigmas three, sessile, two-lobed, somewhat spirally twisted. Placentæ in the axis. Fruit membranous, capsular, triangular, three-celled, loculicide (bursting at the angles) below. Seeds indefinite: testa thin, reticulated. Albumen 0. Embryo oblong: radicle next the hilum.—Herbaceous or suffrutescent plants. Leaves alternate, oblique at the base, with scarious stipules.—Ex. *Begonia* (Plate CXVIII.)

Closely allied to the *Polygonæææ* in several respects, but distinguishable from them by a multitude of characters: some slight relation they also bear to *Loasæææ* and *Onagraræææ*. Mr Lindley once considered them as having affinity with *Saxifragæææ* (*Hydrangæææ*), and Link places them near *Umbelliferæææ*.—The leaves and young shoots are acid, and may be used, like those of the rhubarb, for tarts. The roots are astringent and slightly bitter.

Order 142. *Laurinæææ*. Juss.

Perianth 4-6-cleft, the limb sometimes obsolete: esti-

vation imbricate. Stamens perigynous, definite, opposite to the segments of the perianth; more often twice as many, and in two rows, in which case the outer row is almost always fertile, while such of the inner row as are opposite the inner segments of the perianth are sterile: filaments of the inner row often with glands at their base: anthers 2-4 celled, cells opening by a longitudinal persistent valve from the base to the apex, outer row introrse, inner row extrorse. Ovary single, free or rarely adherent, one-celled: ovule solitary, pendulous: style one: stigma obtuse. Fruit fleshy, naked, or covered by the enlarged and fleshy perianth. Seed one, pendulous. Albumen none. Radicle short, superior: cotyledons large, usually plano-convex and peltate near the base, rarely convolute: plumule conspicuous, two-leaved.—Trees. Leaves exstipulate, alternate, or seldom opposite. Sometimes twining, parasitic, suffrutescent, or herbaceous plants, without leaves.—Ex. *Laurus*, *Cassia*.

Perhaps *Gyrocarpus*, having an adherent ovary, a drupe with two winged processes at its apex, and convolute petiolate cotyledons, ought to form a small suborder. The *Laurinæææ* are allied to the *Berberidæææ* and *Monimæææ* by their valvular anthers.—Cinnamon, camphor, benzoin, and sassafras, are the products of this family: indeed all the species are aromatic, warm, and stomachic.

Order 143. *Hernandiææææ*. BLUME.

Perianth petaloid, tubular, 4-8-parted, deciduous, with a small involucre or outer perianth around the flowers that contain pistils. Stamens perigynous definite, in two rows, of which the outer is often sterile: anthers bursting longitudinally. Ovary free, one-celled: ovule pendulous: style one or none: stigma peltate. Fruit a fibrous drupe. Seed solitary, pendulous. Albumen none. Radicle superior: cotyledons somewhat lobed, shrivelled, oily.—Trees. Leaves alternate, entire.—Ex. *Hernandia*, *Inocarpus*.

Allied to *Laurinææææ* and *Myristicææææ*, differing from the former by its anthers, from the latter by its want of albumen. Mr Lindley has also explained its affinity to the *Thymelæææææ*.—The bark, young leaves, and seed of *Hernandia*, are slightly purgative. The seeds of the *Inocarpus* are eaten, and have a taste similar to chestnuts.

Order 144. *Myristicæææææ*. R. BROWN.

Flowers unisexual. Perianth trifold, in the female deciduous: estivation valvular. Stamens 3-12 (definite): filaments combined closely into a cylinder: anthers connate or distinct, two-celled, extrorse, bursting longitudinally. Ovary free, sessile, one-celled: ovule solitary, erect: style very short: stigma somewhat lobed. Fruit baccate, one-celled, two-valved. Seed solitary, erect, nut-like, covered by a deeply laciniated arillus. Albumen ruminated, between fatty and fleshy. Embryo small, at the base of the albumen. Radicle inferior: cotyledons foliaceous: plumule conspicuous.—Trees, with often a red juice. Leaves alternate, exstipulate, coriaceous, not dotted.—Ex. *Myristica* (Plate CXX.)

Mr Brown remarks that the stamens or anthers, however numerous, are always a multiple of the number of the segments of the perianth, and therefore definite.—The use of the mace or arillus, and albumen, of the nutmeg, is well known, as highly aromatic. The bark, however, has an acrid juice, and the fleshy part of the fruit is caustic.

Order 145. *Proteacæææææ*. Juss.

Perianth more or less deeply 4-divided: estivation valvular. Stamens perigynous, four (one sometimes sterile), opposite the segments of the perianth: anthers two-celled, bursting longitudinally. Ovary solitary, free, sessile or stalked, one-celled: ovules solitary, or rarely in pairs: style simple: stigma discoid, slightly oblique. Fruit dehiscent or indehiscent, one-celled. Seed sometimes winged: testa thick. Albumen none. Embryo straight:

radicle inferior, and below the hilum: cotyledons sometimes more than two.—Shrubs or small trees. Leaves hard, dry, opposite or alternate, exstipulate.—Ex. *Protea*, *Banksia*, *Perseonia*.

A very distinct order, and scarcely to be confounded with any other.—They are handsome evergreens, much prized by gardeners, but of no use except as firewood.

Order 146. *Elæagnææ*. Juss.

Perianth tubular, the limb entire or 2-4-toothed; consisting, in purely stamiferous flowers, of 3-4 tepals; persistent. Stamens three, four, or eight, alternate with the segments of the perianth: anthers nearly sessile, two-celled, erect, bursting on the inner side and longitudinally. Ovary free, one-celled: ovule solitary, ascending, on a short funiculus: style short: stigma simple, subulate, glandular. Fruit a crustaceous achenium, inclosed within the persistent, enlarged, and fleshy tube of the perianth. Seed ascending. Embryo straight, surrounded by a thin fleshy albumen: radicle short, inferior: cotyledons fleshy.—Trees or shrubs. Leaves simple, entire, alternate or opposite, exstipulate, covered beneath with leprous scales. Flowers diœcious or rarely bisexual.—*Elæagnus*, *Hippophaë*.

This order is allied to several in the neighbourhood, and also to Combretaceæ.—The fleshy enlarged perianth of several species is eaten.

Order 147. *Penæacææ*. R. BROWN.

Perianth coloured, more or less deeply 4-divided, regular, persistent. Stamens perigynous, four (or eight, and then the four additional ones are longer than the others), alternate with the segments of the perianth: anthers two-celled, opening inwards and longitudinally. Ovary free, 4-celled: ovules two, collateral in each cell, resupinately erect, or pendulous; foramens near the hilum: style one, entire or 4-fid: stigmas four, or one entire or 4-lobed. Fruit a capsule, 4-celled, 4-valved, loculicide, with no persistent axis: seeds erect (by resupination), or pendulous, two in each cell, rarely solitary, with an imperfect fungus-like arillus at the hilum: testa brittle: nucleus fleshy. Radicle next the hilum.—Shrubs. Leaves opposite, simple, entire, exstipulate. Flowers with two or more bractæ at their base.—Ex. *Penæa*, *Sarcocolla*.

We have examined the structure of the seeds of this order, and have come to the same conclusions as Gærtner, Lindley, and Kunth. The nucleus seems quite homogeneous, solid, and fleshy. There is no part in particular that one can describe as albumen, or cotyledons, or radicle; but from the situation of the foramen in the ovule, it may be presumed that the radicle points to the hilum. In those with erect seeds, the raphe is on the outer side of the seed, that is, at the opposite side from the placenta, and therefore we consider them resupinate.—The Gum-resin called Sarcocolla is obtained from several species.

Order 148. *Thymelææ*. Juss.

Perianth tubular, coloured, 4- (rarely 5-) cleft: estivation imbricate. Stamens definite, perigynous, usually eight, sometimes four (or more rarely two) and then opposite to the segments of the perianth: anthers two-celled, bursting longitudinally. Ovary free, one-celled: ovule one, pendulous: style one: stigma entire. Fruit a nut or a drupe. Albumen none, or thin and fleshy. Embryo straight: radicle short, superior: cotyledons plano-convex: plumule inconspicuous.—Shrubs, or rarely herbaceous plants, with a tough bark. Leaves entire, alternate or opposite, exstipulate.—Ex. *Daphne*, *Passerina*.

Allied to Santalacææ, Elæagnææ, and Proteacææ, from which they are readily known by one or two of the characters given.—The bark is caustic: it is composed of tenacious interlaced fibres, easily separable, which are sometimes worked into cordage: in the lace bark tree

(*Daphne Laghetto*), the inner bark resembles a piece of fine lace; that of *Daphne Gardneri*, and some others, is manufactured into paper. The berries of *D. Laureola* are poisonous to all animals except birds.

Order 149. *Aquilarinææ*. R. BROWN.

Perianth coriaceous, tubular, five-lobed. Stamens monadelphous; ten fertile, alternating with ten that are sterile and sometimes petaloid: anthers erect, two-celled, bursting longitudinally. Ovary free, ovate, of two carpels, one-celled: ovules two, suspended, acuminate, with the foramen at the apex: stigma sessile, simple. Placentas parietal. Capsule pyriform, one-celled, two-valved, loculicide. Seeds two (one to each placenta), arillate, or winged.—Trees. Leaves alternate, exstipulate.—Ex. *Aquilaria*, *Gyrinops*.

The above account of this little-known order we owe to Mr Lindley; and, if his observations be correct, the seed is probably suspended, and the radicle at the opposite extremity from the hilum. On account of the capsule being extremely compressed at the sutures of the valves, it is very difficult to determine whether the margins are not so much introflexed as to meet, and thus form a true dissepiment, and the fruit two-celled, as it has hitherto been described by Gærtner and Lamarck. Gærtner, moreover, describes and figures the seeds of *Gyrinops* as ascending. Nothing yet is known of the internal structure of the seed. Mr Brown arranges this order next to, if it do not form part of, Chailletiacææ, and mentions its relation to Thymelææ. The ambiguous kind of capsule, and appendage to the seeds, seem to point out some affinity with Penæacææ and Polygalææ. If the above description be correct, this order borders very closely on the Samydeæ.

Order 150. *Chailletiacææ*. R. BROWN.

Perianth five-partite, tepals persistent: estivation imbricate (D. C.) or valvate (LINDL.). Stamens inserted into the base of the perianth, and opposite its lobes, with alternating, sterile, petaloid, often bifid, filaments, each of which has usually a gland at its base on the inside: anthers ovate, versatile, two-celled. Ovary free, 2-3-celled: ovules two in each cell, collateral, pendulous: styles 2-3, distinct or combined: stigmas capitate. Fruit an osteocarpium, with the epicarp rather dry and coriaceous, or a capsule, 2-3-celled, one or two cells being often abortive. Seeds solitary in each cell, pendulous. Albumen none. Embryo thick: radicle short, superior: cotyledons fleshy.—Trees or shrubs. Leaves alternate, with two stipules. Peduncles axillary, often cohering with the petiole.—Ex. *Chailletia*, *Tapura*.

Plants with the appearance of *Celtis* (Amentacææ); they are allied somewhat to Terebinthaceæ, and also to Rosacææ.—*Chailletia toxicaria* is said to be poisonous.

Order 151. *Samydeæ*. GÆRTNER.

Perianth usually 5- (sometimes 3-7-) divided, coloured on the inside: estivation somewhat imbricate, seldom completely valvate. Stamens inserted on the tube of the perianth, two, three, or four times as many as its segments, either all fertile, or the alternate ones shorter, villous or ciliated, and sterile: filaments monadelphous at the base: anthers erect, ovate, two-celled. Ovary free, one-celled: ovules indefinite: style one, filiform: stigma capitate, or slightly lobed. Placentæ parietal. Capsule coriaceous, one-celled, 3-5-valved, dehiscing imperfectly; the inside often somewhat pulpy, and coloured. Seeds attached to the valves, not in any evident order, on the papillose or pulpy part, with a fleshy arillus and excavated hilum. Albumen fleshy. Embryo minute: radicle at the opposite extremity from the hilum: cotyledons ovate, foliaceous, plicate.—Leaves alternate, simple, with round and linear pellucid dots mixed, stipulate.—Ex. *Samyda*, *Casearia*.

Arrangement and Characters.

Arrangement and Characters.

Arrange-
ment and
Characters.

The structure of the fruit shows great affinity with the Bixineæ and Flacourtianæ; in some respects also it is allied to Rosaceæ; but it approaches most to Chailletiacæ.—The bark and leaves are said to be slightly astringent.

Order 152. *Homalineæ*. R. BROWN.

Perianth with a short tube, the limb 4-15-partite, with usually as many alternating petaloid segments, either in the same row or forming an inner series. Glands or scales generally present in front of the outer or proper divisions of the perianth. Stamens perigynous, alternating singly, or in parcels of threes or sixes, with the outer segments of the perianth: anthers three-celled, bursting longitudinally. Ovarium partly cohering with the tube of the calyx or free, syncarpous, one-celled: ovules numerous: styles 3-5 (sometimes combined), simple, filiform, or subulate: stigmas 3-5. Placentæ 3-5, parietal. Fruit baccate or capsular, one-celled. Seeds sometimes arillate. Embryo in the axis of a fleshy albumen: radicle inferior, pointing to the hilum: cotyledons foliaceous.—Trees or shrubs. Leaves alternate, with deciduous stipules.—Ex. *Homalium*, *Pineda*, *Azara*.

This order is closely allied to Bixineæ and Samydeæ. Some botanists consider the alternate segments of the perianth as petals, and arrange it near to Rosaceæ.—The properties are unknown.

Div. IV.—*Monochlamydeæ*. D. C.

(10. Epistaminæ. Juss.)

10. Epista-
minæ.

Order 153. *Santalaceæ*. R. BROWN.

Suborder 1. *Exocarpeæ*. Perianth five- (rarely four-) partite, or of three tepals. Stamens perigynous, as numerous as the segments of the perianth, and opposite to them. Ovarium free, or partly cohering with the tube of the perianth: style short or none: stigma obtuse or lobed. Fruit a nut or drupe. Seed solitary. Embryo minute, in a fleshy albumen; radicle superior.—Shrubs or trees. Leaves alternate, exstipulate.—Ex. *Exocarpus*, *Anthobolus*.

Suborder 2. *Santaleæ*. Perianth 4-5-cleft: estivation valvate. Stamens 4-5, opposite the segments of the perianth, and inserted at their base. Ovarium cohering with the tube of the calyx, one-celled: ovules 2-4, pendulous from near the apex of a central placenta: style one: stigma often lobed. Fruit nut-like or drupaceous. Seed solitary. Embryo cylindrical, in the axis of a fleshy albumen: radicle superior.—Trees, shrubs, or herbaceous plants. Leaves alternate, or nearly opposite, exstipulate.—Ex. *Santalum*, *Thesium*.

Suborder 3. *Nysseæ*. Juss. Perianth 4-5-cleft. Stamens (in the bisexual flowers) opposite the segments of the perianth, as numerous, and inserted at their base: in the male flowers usually twice as many as the segments. Ovarium cohering with the tube of the perianth, one-celled: ovule one, occasionally two, pendulous from the apex of the cavity: style one: stigma simple or divided. Fruit drupaceous. Seed solitary. Albumen fleshy. Radicle superior: cotyledons broad, foliaceous.—Trees. Leaves alternate, exstipulate. Flowers polygamous.—Ex. *Nyssa*.

Notwithstanding that *Exocarpeæ* has the fruit wholly or partly free, and therefore belongs to the Peristaminæ, and that *Nysseæ* has no central placenta, and has foliaceous cotyledons, these three suborders can scarcely be separated. *Cervantesia* has petaloid scales alternating with the stamens, and, according to Ruiz and Pavon, an erect seed, an embryo at the apex of the albumen, and an inferior radicle, and therefore may be associated with *Exocarpus* till better understood. Sanders wood is the produce of *Santalum album*.

Order 154. *Aristolochiææ*. Juss.

Perianth tubular, three-cleft, regular, or sometimes very unequal: estivation valvate. Stamens (6-12) a multiple of the segments of the perianth, epigynous, distinct, or adhering to the style and stigmas. Ovarium cohering with the tube of the perianth, 3-6-celled: ovules indefinite, horizontal: style simple, short: stigmas radiating, as numerous as the cells of the ovary. Fruit dry or succulent, 3-6-celled. Seeds numerous. Embryo very minute, placed at the base of a cartilaginous albumen.—Herbaceous plants or shrubs, often climbing. Leaves alternate, with often leafy stipules. Flowers axillary, solitary, bisexual.—Ex. *Aristolochia*, *Asarum*.

In this family the root is the most active part; it has, particularly in *Aristolochia*, a bitter, aromatic, and sometimes even slightly acrid taste. This acidity is predominant in *Asarum*, which is emetic, whilst the other plants are generally stimulant.

Order 155. *Cytineæ*. R. BROWN.

Suborder 1. *Rhizanthææ*. BLUME. Perianth divided: estivation imbricated. Male flowers containing a solid central column, from the apex of which arise some horned processes: filaments none: anthers cohering with the column, extrorse, bursting longitudinally or by terminal pores. Ovarium cohering with the tube of the perianth, one-celled: ovules indefinite. Placentæ several, broad, parietal. Fruit a pulpy berry. Seeds indefinite, very minute.—Parasitic plants. Stem simple. Leaves in the form of scales. Flowers unisexual.—Ex. *Cytinus*, *Rafflesia*.

Suborder 2. *Nepentheæ*. LINK. Perianth four-parted: estivation imbricated. Male flowers containing a solid central column: filaments none: anthers about 16, sessile on and agglomerated into a spherical head at the apex of the column, extrorse, bursting longitudinally. Ovarium free, four-cornered, spuriously four-celled: ovules indefinite: stigma sessile, somewhat four-lobed. Placentæ parietal, constituting the spurious dissepiments. Fruit a capsule, spuriously four-celled, four-valved, loculicide. Seeds ascending, indefinite, very minute: testa loose, setaceous: tegmen ovate oblong, with a filiform process at each extremity. Embryo oblong, in the midst of a fleshy albumen: radicle pointing to the hilum: cotyledons plano-convex.—Leaves alternate, slightly sheathing at the base, with a foliaceous petiole that is pitcher-shaped at the extremity, with a lid-like lamina. Flowers unisexual, densely racemose.—Ex. *Nepenthes*.

Notwithstanding the diversity of habit, we consider these two to be extremely closely allied. In both, the solid central column of the male flowers may be viewed, in whole or in part, as an abortive pistillum. The stamens will thus be epigynous, although in *Nepenthes* the ovary be free. Perhaps Mr Brown was right in uniting this order as a section to the last.—The properties of *Nepenthes* are unknown. *Cytinus* and *Rafflesia* are astringents.

Div. IV.—*Monochlamydeæ*. D. C.

(11. Diclinales. Juss. § 1. Angiospermæ.)

Order 156. *Datisceæ*. R. BROWN.

Flowers unisexual. *Male*: Perianth deeply divided. Stamens several: anthers linear, membranous, two-celled, bursting longitudinally. *Female*: Perianth toothed. Ovarium cohering with the tube of the perianth, one-celled: ovules indefinite, parietal: styles three or four. Placentas parietal, as many as the styles. Fruit capsular, opening at the vertex, one-celled. Seeds indefinite, parietal: testa reticulated. Albumen none. Embryo straight: radicle pointing to the hilum.—Herbaceous branched plants. Leaves alternate, exstipulate.—Ex. *Datisca*, *Tetrameles*.

Arrange-
ment and
Character.

11. Dic-
lines.
1. Ang-
spermæ

Arrangement and Characters.

Mr Lindley considers this as a connecting link between Resedaceæ and Urticeæ; Mr Brown, however, thinks that they differ widely. Both the above genera are dioecious.

Order 157. *Empetreeæ*. NUTTAL.

Flowers unisexual. Perianth gemmaceous, in four (rarely two) imbricated rows: each series of two or three hypogynous scales alternating with those of the next row; the inner often petaloid. Stamens 2-3, equal in number to the scales of each series, and alternating with the innermost, hypogynous: anthers roundish, two-celled, bursting longitudinally at their margin. Ovarium free, seated on the small fleshy discoid torus, with as many cells as stamens, or twice or thrice as many: ovules solitary, ascending: style one, short, deciduous: stigma radiating, multifid. Fruit a nuculanum, seated within the persistent perianth. Seeds solitary in each nucule, ascending: testa membranous: embryo cylindrical, in the axis of a fleshy albumen, and about the same length: radicle inferior: cotyledons semicylindrical, much shorter than the radicle.—Small heath-like shrubs. Leaves alternate, or somewhat verticillate, exstipulate.—Ex. *Empetrum*, *Corema*, *Ceratiola*.

Closely allied to Euphorbiaceæ. It has little or no affinity with the Ericaceæ, with which it is usually arranged; and as little with Coniferæ, where Nuttal places it. Don and most others view the inner series of the perianth as petals, the next as a calyx, and the outer, when present, as bracteas, and therefore consider them as allied to Celastriaceæ.

Order 158. *Euphorbiaceæ*. JUSS.

Flowers unisexual. Perianth lobed (sometimes wanting), with various internal glandular or petaloid scales (abortive petals) alternating with the lobes. Stamens definite or indefinite, distinct or monadelphous: anthers two-celled. Ovarium free, sessile, or rarely stalked, 2-3- or sometimes many-celled; carpels arranged round a central column: ovules solitary or in pairs, suspended: styles equal in number to the cells, distinct or combined, sometimes none: stigmas several, or one with several lobes. Fruit of two, three, or more cocci, which are usually distinct and elastically two-valved, sometimes indehiscent or closely cohering. Seeds solitary or in pairs, suspended, arilate. Embryo inclosed in a fleshy albumen: radicle superior, pointing to the hilum: cotyledons flat.—Trees, shrubs, or herbaceous plants, often lactescent. Leaves usually with stipules, opposite or alternate, sometimes none.—Ex. *Euphorbia* (Plate CXXI.), *Buxus*, *Croton*, *Ianipha* (Plate CXXII.)

This order is usually arranged among the Monochlamydeæ, and next the Urticeæ; but if Coriariæ belong to the Thalamifloræ, so ought the Euphorbiaceæ, for the petaloid bodies, often in this family reduced to mere glands, are of the same nature in both. The stigmas of many Euphorbiaceæ resemble much those of Coriariæ; and perhaps the true place for them in a linear series is between the Coriariæ and Celastrineæ.—The plants of this order are acrid, caustic, and poisonous. Their deleterious effects are owing to the milky juice which most of them possess; but they may be deprived of this very easily by means of heat, so that the root of the *Ianipha Manioc* becomes a wholesome food. The albumen of the seed contains much fat and sweet oil, but the embryo is acrid and purgative. It is impossible to give here the various modifications of the properties to be found in this family. They are discussed at length by Ad. de Jussieu, in his treatise on this family.

Order 159. *Urticaceæ*. JUSS.

Suborder 1. *Urticeæ*. JUSS. Flowers unisexual, scattered or clustered. Perianth membranous, lobed, persistent.

Stamens definite, distinct, inserted into the base of the perianth, and opposite its lobes: filaments sometimes curved inwards during estivation. Ovarium free, one-celled: ovule solitary, erect: stigma simple. Fruit an indehiscent nut, surrounded by the membranous or fleshy perianth. Seed solitary, erect. Albumen 0, or very thin. Embryo straight, or curved, or spiral: radicle superior, remote from the hilum.—Trees, shrubs, or herbaceous plants. Leaves alternate, hispid, or scabrous, stipulate.—Ex. *Urtica*, *Cannabis*, *Humulus*.

Suborder 2. *Ulmææ*. MIRBEL. Flowers bisexual or polygamous, scattered. Perianth campanulate, divided. Stamens definite, inserted into the base of the perianth, erect during estivation: ovarium free, two-celled: ovules solitary, pendulous: style 0: stigmas two. Fruit one or two-celled (one of them abortive), a samara or a drupe. Seed one, pendulous: albumen 0, or very thin. Embryo straight: radicle superior: cotyledons foliaceous.—Trees or shrubs. Leaves simple, alternate, stipulate.—Ex. *Ulmus*, *Celtis*.

Suborder 3. *Artocarpeæ*. R. BROWN. Flowers unisexual, in heads or catkins. Perianth usually divided, sometimes tubular or entire. Stamens solitary or several, straight during estivation. Ovarium free, or rarely cohering with the perianth, 1-2-celled: ovule suspended: style one, filiform: stigma bifid. Fruit a sorosus or syconus, which is sometimes, but very rarely, reduced to a single flower. Seed solitary, suspended. Albumen thin or inconspicuous. Embryo straight or curved: radicle pointing superior.—Trees, shrubs, or herbaceous plants, with milky juice. Leaves alternate: stipules deciduous, convolute in veneration. Ex. *Artocarpus* (Plate CXXV.), *Morus*, *Ficus*.

We follow Richard and some others in combining these three. The Ulmaceæ, however, from the two-celled ovarium, ought perhaps, as has been done by De Candolle and Duby, to be united to the Amentaceæ. Mr Brown says that they should be rejected on account of the pendulous ovules. But then he states Artocarpeæ to have the ovules erect. Mr Lindley, however, finds them suspended. We have in several species observed them to be peritropal, and in general attached to a point opposite the base of the style: the radicle is however always superior, wherever be the hilum.—In the Urticeæ the fibres of the stem are very tenacious. The leaves of the hemp are narcotic. The hop is extremely bitter, and the effluvia is said to cause sleep. The nettles are well known for the stinging property of the hairs on their leaves. The bark of the Elm (*Ulmus*) is bitter and astringent. The fruit of most of the Artocarpeæ is edible; but the juice is usually acrid, and contains more or less of caoutchouc. The *Antiaris toxicaria*, the celebrated Upas or poison-tree of Java, belongs to this tribe. *Brosimum galactodendron*, or the cow-tree of Humboldt, is a solitary instance of the milk being wholesome. The banyan-tree of India is the *Ficus religiosa*.

Order 160. *Monimieæ*. JUSS.

Flowers unisexual, collected together, the males and females into different involucre: involucre toothed or lobed, valvular during estivation. Perianth 0. Stamens numerous, covering the whole interior of the involucre: anthers two-celled, bursting longitudinally. Ovaria several, sessile, and inclosed within the tube of the involucre, each with one style and one stigma: ovule solitary, pendulous. Fruit a dry syconus. Seed pendulous. Embryo in the midst of a copious albumen: radicle superior.—Trees or shrubs. Leaves opposite, exstipulate. Flowers axillary, in short racemes.—Ex. *Monimia*, *Boldoa*.

Closely allied to the Urticaceæ.—The bark and leaves give out when bruised a highly aromatic smell.

Arrangement and Characters.

Arrange-
ment and
Characters.

Order 161. *Atherospermeæ*. R. BROWN.

Flowers unisexual, collected together, males and females usually in distinct, rarely in the same, involucre: involucre tubular, divided at the extremity, the divisions usually in two rows, of which the inner, and sometimes all, are petaloid, accompanied in the pistilliferous involucre with a few scales. Stamens in the purely stamiferous involucre very numerous, inserted into the bottom of the involucre, mixed with scales; in the involucre having also pistilla, they are fewer, and arise from its orifice: anthers adnate, two-celled, bursting with a valve that separates from the base to the apex. Ovaria several, usually indefinite: ovule solitary, erect: styles simple, sometimes arising from the side or the base: stigma undivided. Achenia furnished with the persistent styles, become feathery, included within the enlarged tube of the involucre. Seed solitary, erect. Embryo short, at the base of a soft fleshy albumen: radicle inferior.—Trees. Leaves opposite, exstipulate. Flowers axillary, solitary.—Ex. *Atherosperma*, *Laurelia*.

The anthers indicate some affinity to the Berberideæ and Laurineæ. Mr Brown and Mr Lindley consider the involucre a perianth. We have been induced to differ from them only by the analogy subsisting between this order and Monimieæ, with which they agree in many very important points; like them they are aromatic.

Order 162. *Lacistemeæ*. MARTIUS.

Perianth in several narrow divisions, covered by a dilated bractea. Stamen one, hypogynous: anther two-celled, separated by a thick two-lobed connectivum, bursting transversely. Torus a fleshy disc. Ovarium free, one-celled: ovules several, ascending: style scarcely any: stigmas two, three, or four; small, subulate, spreading. Placentas parietal. Fruit capsular, 2-3- or 4-valved, loculicide. Seed usually (by abortion) solitary, suspended from a long funiculus, with a fleshy arillus: testa crustaceous. Embryo in a fleshy albumen: radicle straight, cylindrical, superior: cotyledons flat.—Small trees or shrubs. Leaves simple, alternate, exstipulate. Flowers in axillary clustered catkins.—Ex. *Lacistema*.

Martius and Lindley attribute to this a fleshy albumen; St Hilaire and Kunth say there is none. Some authors suppose the perianth to consist only of four pieces, accompanied with one or more bractea, and the whole surrounded by a large bractea. We, however, are rather inclined to consider the supposed perianth as mere processes from the torus, and consequently this tribe approaches very near to the Chlorantheæ. Although all the flowers are bisexual, the upper ones only of the catkin are fertile, whence we have arranged the order among the Diclinales, with which it is otherwise most allied.

Order 163. *Chlorantheæ*. R. BROWN.

Flowers without a perianth, bisexual or unisexual, with a supporting scale. Stamens definite, lateral; if more than one, connate: filament adhering slightly to the ovary: anthers one-celled, bursting longitudinally, each adnate to a fleshy connectivum, which coheres laterally in various degrees, so as to represent usually only one anther with several cells. Ovarium one-celled, ovule solitary, pendulous: stigma simple, sessile. Fruit drupaceous, indehiscent. Seed pendulous. Embryo minute, at the apex of a fleshy albumen: radicle inferior, pointing to the opposite extremity from the hilum: cotyledons divaricate.—Herbaceous or suffrutescent plants. Stems jointed. Leaves opposite, simple, with sheathing petioles, and minute intervening stipules. Flowers in terminal spikes.—Ex. *Chloranthus*, *Ascarina*, *Hedyosmum*.

Allied to Piperaceæ. "Their anthers consist of a fleshy mass, upon the face of which the cell lies that bears the pollen. Whether these anthers are one or two-celled, is a

matter of doubt; one botanist considering those which have two cells to be double anthers, another considering those with one cell to be half anthers."—(Lindl.) *Chloranthus officinalis* has an aromatic fragrant smell, which is combined in the root with a somewhat bitter flavour, giving it the same properties as *Aristolochia serpentaria*.

Order 164. *Piperaceæ*. RICHARD.

Suborder 1. *Piperineæ*. Flowers without a perianth but with a bractea, bisexual. Stamens definite or indefinite, arranged on one side, or all round the ovary, to which they adhere more or less: anthers one or two-celled, with or without a fleshy connectivum: pollen smooth. Ovarium solitary, free, one-celled: ovule solitary, erect: stigma simple, sessile, rather oblique. Fruit somewhat fleshy, one-celled. Seed erect. Embryo inclosed in a fleshy endosperm, placed on the outside of the perisperm, at the opposite extremity from the hilum.—Shrubs or herbaceous plants. Leaves opposite (sometimes alternate by abortion), or verticillate, exstipulate. Flowers in spikes.—Ex. *Piper*, *Peperomia*.

Suborder 2. *Saurureæ*. RICHARD. Flowers without a perianth, seated on a scale or bractea, bisexual. Stamens three or six, clavate, hypogynous or cohering with the angles of the germen, persistent: anthers continuous with the filament, with a thick connectivum, and two lobes bursting longitudinally. Ovaria four, apocarpous, with one ascending ovule and a sessile recurved stigma to each; or syncarpous, consisting of three or four carpella, one or 3-4-celled, with several ascending ovules, and 3-4 sessile recurved stigmas. Fruit either consisting of four fleshy achenia, or a one or 3-4-celled capsule, opening at the apex and containing several ascending seeds. Seeds with a membranous testa. Embryo minute, inclosed in a fleshy endosperm, situated on the outside of a hard mealy perisperm at the extremity remote from the hilum.—Herbaceous plants, growing in marshy places, or floating in water. Leaves alternate, stipulate. Flowers in spikes, rarely with a four-leaved involucre at the base of the spike.—Ex. *Saururus*, *Aponogeton*, *Houttuynia*.

This order has floated for some time between the Dicotyledones and Monocotyledones; but what Richard and others took for a monocotyledonous embryo, proves now to be merely the embryonic sac, or endosperm. As to *Houttuynia*, we have referred it here, notwithstanding several botanists have considered it as more allied to the Aroidæ.—The common pepper is well known as pungent, stimulant, and aromatic, and this represents the ordinary property of the Piperineæ.

Order 165. *Amentaceæ*. JUSS.

Suborder 1. *Salicineæ*. RICHARD. Flowers in unisexual amenta. Stamens distinct or monadelphous: anthers two-celled. Ovarium free, one or two-celled: ovules numerous, erect, attached to the bottom of the cell or to the base of two parietal placentas: style one or none: stigmas two. Fruit a coriaceous capsule, one or two-celled, two-valved, loculicide. Seeds numerous, adhering as in the ovary, comose. Albumen 0. Embryo straight: radicle pointing to the hilum.—Trees or shrubs. Leaves alternate, with stipules that are often deciduous.—Ex. *Salix*, *Populus*.

Suborder 2. *Myricææ*. RICH. Flowers unisexual in an amentum, which is sometimes globose. Stamens one or several, each subtended by a scale: anthers two-celled, 2-4-valved, opening longitudinally. Ovarium one-celled, with several hypogynous scales: ovule solitary, erect: stigmas two, subulate. Fruit drupaceous, often covered with waxy granules; surrounded by the scales of the ovary become fleshy and adherent; or dry and dehiscent, with the scales distinct. Seed solitary, erect. Albumen 0. Embryo straight: radicle short, superior: cotyledons

Arrange-
ment and
Characters.

Arrangement and Characters. two, plano-convex.—Shrubs with resinous glands and dots, or leafless shrubs or trees, with filiform branches bearing membranous toothed sheaths. Leaves alternate.—Ex. *Myrica*, *Casuarina*.

thers erect, two-celled, bursting longitudinally. *Females* with a single or double perianth: the exterior four-parted, the inner (when present) of four pieces. Ovarium cohering with the perianth, one-celled: ovule solitary, erect: styles one or two, very short, or none: stigmas large, either two and lacerated, or discoid and four-lobed. Fruit (a drupe) fleshy, containing a 2-4-valved, one-celled, putamen. Seed four-lobed, with a membranaceous testa. Albumen none. Embryo large: radicle superior: cotyledons fleshy, two-lobed, wrinkled.—Trees. Leaves alternate, without pellucid dots or stipules.—Ex. *Juglans*.

Arrangement and Characters.

Suborder 3. *Betulineæ*. RICH. Flowers unisexual in an amentum, the males sometimes having a membranous toothed perianth (or rather an expansion of the torus). Stamens distinct, or rarely monadelphous: anthers two-celled. Ovarium two-celled: ovules definite, pendulous: style one or none: stigmas two. Fruit membranous, indehiscent, by abortion one-celled. Seeds pendulous, not comose. Albumen 0. Embryo straight: radicle superior.—Trees or shrubs. Leaves alternate: stipules deciduous.—Ex. *Betula*, *Alnus*.

Suborder 4. *Platanææ*. JUSS. Flowers in unisexual globose amenta. Stamens distinct, with several small scales and appendages mixed among them: anthers linear, two-celled. Ovaria terminated by a thick style, with the stigma lateral and adnate: ovules solitary or in pairs, pendulous. Fruits in consequence of mutual compression clavate, bony, with a persistent recurved style. Seeds solitary, or rarely in pairs, pendulous, elongated: testa thick. Embryo long, cylindrical, in the axis of a fleshy albumen; radicle inferior.—Trees or shrubs. Leaves alternate, with scarious sheathing stipules.—Ex. *Platanus*.

Suborder 5. *Cupuliferææ*. RICH. Flowers unisexual, in amenta, the females sometimes aggregated. Stamens 5-20, generally distinct, inserted into the base of the scales or of a membranous perianth. Ovarium seated in a coriaceous involucre (*cupula*), crowned by the rudiments of an adherent perianth, plurilocular: ovules two or one, pendulous: stigmas several, nearly sessile, distinct. Fruit a gland. Seed solitary, pendulous. Albumen 0. Embryo large: radicle superior, small: cotyledons plano-convex.—Trees or shrubs. Leaves alternate, exstipulate.—Ex. *Quercus*, *Corylus*, *Fagus*.

We leave this order entire, nearly as done by Jussieu. With regard to the suborders, their limits are not yet well fixed. Thus De Candolle excludes *Liquidamber* from the *Myricææ*, on account of the globular catkins and palm-nerved leaves, and alters materially the character of *Platanææ* for its reception; but although more allied in habit to *Platanus*, these two genera seem to differ widely in the structure of the seed.—As to medical properties, the *Salicineææ* have the bark bitter and febrifugal. The *Myricæææ* are aromatic. The bark of *Betulineææ* is astringent and somewhat febrifugal. *Cupuliferæææ* are tonic, stomachic, and febrifugal. The bark of the oak is employed for tanning. Cork is the bark of the *Quercus Suber*. The Hazel, Beech, and Sweet Chestnut, belong to this suborder.

Order 166. *Stilagineææ*. AGARDH. Flowers unisexual. Perianth 3-5-partite. Stamens two or more, arising from a tumid receptacle: filaments capillary: anthers erect, two-lobed, with a fleshy connectivum, and vertical cells opening transversely. Ovarium free: ovules two: stigma sessile, 3-4-toothed. Fruit drupaceous. Seed solitary, suspended. Embryo in the midst of a copious fleshy albumen: cotyledons foliaceous.—Trees or shrubs. Leaves alternate, with deciduous stipules.—Ex. *Stilago*, *Antidesma*.

An order by no means understood. In some points it appears to approach the *Amentaceæææ*, particularly *Cupuliferææææ* and *Platanææææ*.

Order 167. *Juglandææææ*. D. C. Flowers unisexual. *Males* in an amentum. Perianth scaly, oblique, irregularly lobed. Stamens inserted on the receptacle, indefinite: filaments short, distinct: an-

Div. IV.—*Monochlamydeææææ*. D. C.

(11. *Diclinesææææ*. JUSS. § 2. *Gymnospermeææææ*.)

11. *Diclinesææææ*.
2. *Gymnospermeææææ*.

Order 168. *Conifereææææ*. JUSS.

Flowers unisexual. *Male* florets consisting of one or several monadelphous stamens, collected in an amentum about a common rachis: anthers two or many-lobed, bursting outwardly; often terminated by a crest, which is an uncovered portion of the scale out of which each stamen is formed. *Females* usually in cones, sometimes solitary. Ovarium none (in the solitary flower), or spread open (in the cone) and resembling a flat scale, destitute of style or stigma, arising from the axil of a membranous bractea: ovules exposed; in the cones in pairs on the face of the ovary, inverted; in the solitary flower erect. Fruit, a solitary naked seed, or a cone. Seeds with a hard crustaceous testa. Embryo in the midst of a fleshy oily albumen: radicle next the apex of the seed, having an organic connection with the albumen.—Trees or shrubs; trunk branched, abounding in resin. Leaves with the veins parallel to each other.—Ex. *Pinus*, *Taxus*, *Thuja*.

There are often more than two cotyledons, but they are opposite, whence perhaps they may be viewed as only two, but multipartite. "The structure of the *Conifereæææææ* differs so widely from that of the true (or angiospermous) *Dicotyledonsæææææ*, that a single glance will in general enable us to distinguish the one tribe from the other. In the *Conifereæææææ* there is only one regular system of pores, resembling a piece of the most delicate net-work. Each mesh is bounded by straight lines crossing each other at nearly right angles, and the concentric lines of the meshes almost always approximate each other at the outer edge of each annual layer of the wood. The structure of the true *Dicotyledonsæææææ* consists of a system of vessels separated from each other by masses of cellular matter, and the vessels or pores are always bounded by curved lines."¹—This order is of great importance on account of its timber. But it is also valuable for its resinous productions; various kinds of pitch, turpentine, and balsams being procured from the different species. The large seeds of some are eaten, and are wholesome. The berries of some species of *Juniper* are diuretic.

Order 169. *Cycadeæææææ*. RICH.

Flowers unisexual. *Males* naked, collected into cones; each floret of a single scale or anther, bearing the pollen on its under surface in two-valved cells, which cohere together by twos, threes, or fours. *Females* either collected in cones, or surrounding the central bud in the form of contracted leaves or scales (the expanded ovaria). Ovules

¹ Nicol in Jameson's *New Phil. Journal*, vol. x. p. 362.

Arrangement and Characters.

exposed on the margin of the scale or contracted leaf. Embryo in the midst of a fleshy or horny albumen: radicle next the apex of the seed, from which it hangs by a long funiculus, with which it has an organic connection.—Trees with a simple cylindrical trunk. Leaves pinnatisect; vernation gyrate.—Ex. *Cycas* (Plate CXXVI.), *Zamia*.

These trees increase by the development of a single terminal leaf-bud. The wood consists of concentric circles, the cellular rings between which are very loose. They seem to hold a middle rank between the Coniferæ and Palms.—They abound in a mucilaginous juice. A kind of Sago is obtained from the soft centre of *Cycas circinalis*.

B. ENDOGENÆ. D. C. (MONOCOTYLEDONES. JUSS.)

12. Monoepigynæ.

(12. Monoepigynæ. JUSS.)

Order 170. *Balanophoræ*. RICH.

Flowers unisexual, in dense heads; the receptacle covered with scales or bristles, and also here and there with peltate thick scales; rarely naked. Male flowers pedicellate. Perianth tripartite, equal, spreading, or in place of it a thick truncate obconical scale. Stamens epigynous, 1-3: filaments united: anthers connate, opening longitudinally. Females: Ovarium cohering with the perianth, and crowned by its limb, one-celled: ovule solitary, pendulous: style one, rarely two, filiform: stigma simple, terminal, slightly convex. Achenium crowned by the remains of the limb of the perianth, roundish. Embryo very minute, roundish, inclosed in a hollow on the surface of a fleshy cellular albumen.—Fungous-like, parasitical plants: stem naked or covered with imbricated scales.—Ex. *Balanophora*, *Helosis*, *Cynomorium*.

Professor Richard considered this order most nearly allied to the Hydrocharideæ: there is also some affinity with the Cytinæ. Agardh makes them a section of Urticæ. May not what is taken for the embryo be the endosperm, and what is called albumen the perisperm?—*Cynomorium* is astringent.

Order 171. *Hydrocharideæ*. JUSS.

Flowers spathaceous, uni- or rarely bisexual. Perianth with the limb six-partite; the three exterior segments herbaceous, the three inner petaloid. Stamens epigynous, definite or indefinite. Ovarium solitary, cohering with the tube of the perianth, one or spuriously many-celled: ovules indefinite: stigmas 3-6. Placentas parietal, sometimes projecting into the centre of the ovarium. Fruit dry or succulent, indehiscent, one- or spuriously many-celled. Seeds numerous, ascending: testa thin, membranous. Albumen none. Embryo straight, cylindrical: radicle at the opposite extremity from the hilum.—Floating plants. Flowers spathaceous.—Ex. *Hydrocharis*, *Stratiotes*, *Vallisneria*.

Allied in some points to the Alismaceæ, but differing in the cohering ovarium. The spiral peduncles of *Vallisneria*, and the process of fertilization in that plant, are highly curious.

Le Rhône impétueux, sous son onde écumante,
Durant six mois entiers nous dérobe une plante
Dont la tige s'allonge en la saison d'amour,
Monte au-dessus des flots, et brille aux yeux du jour.
Les mâles, dans le fond jusqu'alors immobiles,
De leurs liens trop courts brisent les nœuds débiles,
Voguent vers leur amante, et libres dans leurs feux,
Lui forment sur le fleuve un cortège nombreux:
On diroit une fête où le dieu d'hyménée
Promène sur les flots sa pompe fortunée;
Mais les tems de Vénus une fois accomplis,
La tige se retire en rapprochant ses plis,
Et va mûrir sous l'eau sa semence féconde.¹

Order 172. *Orchideæ*. JUSS.

Perianth with a ringent, six-partite, limb: outer segments usually coloured, of which the odd one is often uppermost by a twisting of the ovary: inner segments more petaloid, the odd one or the *labellum* being frequently lobed and unlike the others, and often spurred at the base. Stamens in a double row, three, epigynous, united in a central column; either the two lateral (opposite to the lateral inner segment of the perianth) or the central one (opposite to the odd exterior segment) being abortive; very rarely all the three fertile: anther persistent or deciduous, two, or four, or eight-celled: pollen powdery, or cohering in definite or indefinite waxy masses. Ovarium one- (very rarely three-) celled, cohering with the tube of the perianth: ovules indefinite: style forming part of the column of the stamens: stigma a viscid cavity in front of the column, communicating directly with the ovary by an open canal. Placentas three, parietal. Capsule three-ribbed, three-valved, rarely baccate. Seeds very numerous: testa loose, reticulated. Albumen none. Embryo a solid fleshy mass.—Herbaceous plants. Leaves simple, quite entire.—Ex. *Orchis*, *Goodyeria*, *Epidendrum*, *Cypripedium*.

Nearly allied to the following order. The botanical world have to thank Mr Brown for first giving a correct view of the organization of the flowers of these plants. *Apostasia* has a regular flower, a three-celled ovary, and three perfect stamens.—The Orchideæ are beautiful to the eye, but of little use. Salep is obtained from the roots of *Orchis mascula*. Vanilla, used so much for mixing with chocolate, is the succulent fruit of a West Indian species.

Order 173. *Amomeæ*. JUSS.

Suborder 1. *Scitamineæ*. R. BROWN. Perianth in a double row; exterior tubular, three-lobed, short; inner elongated, tubular, trifid, segments nearly equal. Stamens in two rows; the outer (projections of the torus) sterile, resembling a trifid tubular corolla, of which the intermediate segment (*labellum*) is larger than the rest (which are sometimes nearly abortive), and often three-lobed: stamens of the inner row distinct, two sterile; one intermediate, fertile, at the opposite side of the flower from the labellum: filament not petaloid, often extended beyond the anther: anther two-celled, opening longitudinally. Ovarium three-celled, or imperfectly so: ovules several: style filiform: stigma dilated, hollow. Placenta in the axis. Fruit usually capsular, three-celled: occasionally baccate. Seeds numerous. Embryo inclosed in a membranous endosperm, surrounded by a farinaceous albumen, that is deficient near the hilum.—Herbaceous aromatic plants. Stems simple. Leaves sheathing: midrib central, with numerous diverging simple veins. Flowers arising from spathaceous bractæas.—Ex. *Amomum*, *Zingiber*.

Suborder 2. *Canneæ*. R. BROWN. Perianth in a double row; exterior three-lobed, short; interior elongated, tubular, trifid, segments nearly equal. Stamens in a double row; the outer (projections of the torus) sterile, resembling a trifid tubular corolla, of which one of the lateral segments is unlike the others: stamens of the inner row distinct, petaloid; two sterile, one lateral fertile: filament petaloid, entire or two lobed: anther opening longitudinally, one-celled, seated on the margin of the filament (the other cell belonging to the other margin being always abortive). Ovarium three-celled (rarely one-celled), ovules solitary and erect, or numerous and attached to the axis: style petaloid or swollen: stigma either the naked apex of the style, or hollow, cucullate, and incurv-

¹ Castel, *Poème sur les Plantes*.

Arrangement and Characters.

ed. Fruit capsular, three-celled; or baccate, one-celled, one-seeded. Albumen (perisperm) hard, somewhat farinaceous. Embryo straight, without endosperm: radicle lying against the hilum.—Herbaceous plants, not aromatic. Leaves and inflorescence as in the Scitamineæ.—Ex. *Maranta, Canna, Phrynium*.

The above view of the structure of these plants being nearly that adopted by Lestiboudois, Richard, and Lindley, is somewhat at variance with that proposed by Mr Brown, who considers the outer row of our perianth as accessory, and what is here called the outer sterile stamens to be the inner row of the perianth. But this order is closely allied to the Musaceæ, and the affinity is confirmed by the supposition of six stamens, although only one be perfect.—The Scitamineæ are aromatic, cordial, and stomachic: Ginger, Galangale, and Zedoary are the roots or rhizoma; Cardamoms are the seeds of several species. The Canneæ are scarcely or not at all aromatic, and hence the fecula which abounds in the root furnishes a delicate article of food. Arrow-root is obtained from more than one species, but principally from *Maranta arundinacea*, the juice of the root of which is said to be a cure for wounds inflicted by poisoned arrows.

Order 174. *Musaceæ*. JUSS.

Perianth six-cleft, in two rows, more or less irregular. Stamens six (some occasionally abortive), inserted on the middle of the divisions of the perianth: anthers linear, two-celled, introrse, often with a membranous petaloid crest. Ovarium cohering with the tube of the perianth, three-celled: ovules numerous, or rarely only three: style simple: stigma usually three-lobed. Fruit either a three-celled, three-valved, loculicidal capsule; or succulent and indehiscent. Seeds sometimes surrounded by hairs: testa usually crustaceous. Embryo in the axis of a farinaceous albumen.—Stem scarcely any. Leaves sheathing, and forming a spurious stem: limb separated from the petiole by a round tumour, having a midrib with fine parallel diverging veins. Flowers spathaceous.—Ex. *Musa, Streitzia*.

By comparing this with the last order, their relation will be readily perceived.—The young shoots of the Banana (*Musa sapientum*) are eaten as a delicate vegetable. The fruit of the same is nourishing, and either it, or that of the Plantain (*M. paradisiaca*), in some parts of the world, forms the principal food of the natives.

Order 175. *Irideæ*. JUSS.

Perianth tubular, six-parted, in two often unequal rows. Stamens three, epigynous, distinct or monadelphous, opposite the outer segments of the perianth: anthers two-celled, bursting outwardly. Ovarium cohering with the tube of the perianth, three-celled: ovules numerous: style one: stigmas three, dilated, often petaloid, and sometimes two-lipped. Capsule three-celled, three-valved, loculicidal. Seeds numerous. Embryo cylindrical, inclosed within a fleshy or horny albumen: radicle pointing to the hilum.—Plants usually herbaceous. Leaves equitant and distichous, except in *Crocus*. Flowers with spathaceous bractæ.—Ex. *Iris, Ixia, Crocus*.

Allied on the one hand to the Amomeæ, and on the other to the Amaryllideæ.—Of no great utility. The orris, however, is the root of *Iris Florentina*. Some other species of *Iris* are purgative. Saffron is the dried stigmas of a *Crocus*. The root of the common *Iris*, when cut by an iron or steel knife, yields a beautiful purple dye.

Order 176. *Burmannieæ*. SPRENG.

Perianth petaloid, tubular, six-cleft, the three outer segments carinate, the three inner minute. Stamens three, inserted on the tube, opposite the inner segments of the perianth, with sometimes three alternating sterile filaments: anthers erect, two-celled, opening transversely, with a

fleshy connectivum. Ovarium cohering with the tube of the perianth, three-celled, the cells being opposite the inner segments of the perianth: ovules indefinite: styles single: stigma three, dilated. Capsule crowned by the withered perianth, three-celled, three-valved. Seeds indefinite, minute, striated.—Herbaceous plants, with radical equitant leaves.—Ex. *Burmanniea*.

Allied to Irideæ in many respects, but differing by the fertile stamens being alternate with the outer segments of the perianth; but this ought perhaps to be viewed as accidental (however constant), as the return to the symmetrical arrangement is exhibited in the position of the carpellary leaves.

Order 177. *Hæmodoreæ*. R. BROWN.

Suborder 1. *Hæmodoreæ*. Perianth petaloid, six-cleft. Stamens inserted on the perianth, either three and opposite the inner segments of the perianth, or six: anthers bursting inwardly. Ovarium cohering with the tube of the perianth, or very rarely free, of three carpels, three- or rarely one-celled: ovules 1-2, or numerous, to each carpel: style simple: stigma undivided. Fruit capsular, three valved, seldom indehiscent, somewhat nucamentaceous. Seeds definite and peltate, or indefinite: testa chartaceous. Embryo minute, a farinaceous albumen: radicle next the hilum.—Leaves equitant.—Ex. *Hæmodorum, Dilatris*.

Suborder 2. *Wachendorfiæ*. Perianth petaloid, six-parted, irregular. Stamens three, inserted on the base of the inner segments of the perianth: anthers bursting inwardly. Ovarium free, three-celled: ovules solitary or numerous: style simple: stigma undivided. Fruit capsular, three-celled, three-valved. Seeds roundish.—Leaves equitant.—Ex. *Wachendorfia, Xiphydium*.

This order is related both to Irideæ and Amaryllideæ. *Wachendorfiæ*, though allied in many respects to *Hæmodoreæ*, might perhaps, without great violence, be rather placed between Liliaceæ and Bromeliaceæ.—The roots of *Hæmodorum, Dilatris*, and *Wachendorfia*, yield a red dye.

Order 178. *Amaryllideæ*. R. BROWN.

Perianth petaloid, regular, six-cleft; the outer segments overlapping the inner, which are equitant. Stamens six (rarely more, and then hexadelphous), inserted on the perianth, sometimes cohering by their dilated bases into a kind of cup: anthers bursting inwardly. Ovarium cohering with the tube of the perianth, three-celled: ovules indefinite, rarely 1-2: style one (rarely three): stigma three-lobed (rarely three). Fruit either a three-celled, three-valved, loculicidal capsule, or baccate. Seeds numerous in the capsular, 1-2 in the baccate species: testa neither black nor crustaceous. Albumen fleshy. Embryo somewhat straight: radicle next the hilum.—Roots usually bulbiferous, rarely fibrous. Leaves ensiform, with parallel veins. Flowers with spathaceous bractæ.—Ex. *Amaryllis, Narcissus*.

Allied to the *Hæmodoreæ*, but much more to Liliaceæ and Asphodeleæ. The coronas of *Narcissus* and some other genera may be viewed either as a second row of sterile cohering filaments between the fertile ones and the perianth, or as a process of the torus, both considerations tending to prove that the perianth is more of the nature of a calyx than a corolla. Although having three styles and stigmas, we refer *Campynema* here.—The juice of the root of *Hæmanthus toxicarius* is poisonous. The bulbs of some species of *Narcissus* and *Pancratium* are emetic. Some *Alstræmeria* are diuretic. *Amaryllis ornata* is astringent.

Order 179. *Hypoxideæ*. R. BROWN.

Perianth petaloid, usually six-parted, regular: estivation imbricate. Stamens inserted into the base of the

Arrangement and Characters.

segments, equal to them in number: anthers introrse. Torus an epigynous fleshy disc. Ovarium cohering with the tube of the perianth, three-celled: ovules numerous: style single: stigma three-lobed. Capsule indehiscent, sometimes succulent. Seeds numerous: testa black and crustaceous: hilum lateral, rostelliform. Embryo in the axis of a fleshy albumen.—Herbaceous, stemless (or nearly so) plants. Leaves plicate.—Ex. *Hypoxis*, *Curculiago*.

Allied to *Hæmodoraceæ*, and also to *Asphodoleæ*, particularly in the black crustaceous seed.

Order 180. *Barbaceniceæ*.

Perianth petaloid, six-partite, regular, in a double series. Stamens six, or in six (rarely three) fascicles, inserted into the base of the segments: anthers introrse. Torus an epigynous fleshy disc. Ovarium cohering with the tube of the perianth, three-celled: ovules numerous: style single: stigma three-lobed. Capsule three-celled, three-valved. Seeds indefinite, cuneiform: testa coriaceous, furrowed: hilum prominent.—Ex. *Barbacenia*, *Vellozia*, *Xerophyta*.

An order pointed out by Mr Don, as holding a middle place between *Hypoxideæ*, and *Bromeliaceæ*.

Order 181. *Dioscoreineæ*.

Suborder 1. *Dioscoreæ*. R. BROWN. Flowers uni- (rarely bi-) sexual. Perianth six-cleft, equal. Stamens six, distinct, or rarely monadelphous, inserted into the base of the segments of the perianth: anthers introrse. Ovarium cohering with the tube of the perianth, three-celled: ovules one or two in each cell: style trifid: stigmas undivided. Fruit a thin compressed capsule, with two of the cells sometimes abortive. Seeds flat: testa membranaceous. Embryo small, lying in a large cavity of a somewhat horny albumen, near the hilum.—Twining shrubs. Leaves alternate, occasionally opposite, veins generally reticulated. Flowers small, spiked, each with 1-3 bractæ.—Ex. *Dioscorea*, *Testudinaria*.

Suborder 2. *Tameæ*. GRAY. Flowers unisexual. Perianth petaloid, six-parted. Stamens six, inserted into the base of the segments of the perianth. Ovarium three-celled: ovules two in each cell, erect: style one: stigmas three, reflexed, acutely bifid. Fruit fleshy, three-celled, indehiscent. Seeds ovate: testa membranaceous. Albumen between cartilaginous and horny. Embryo minute, lying at the extremity remote from the hilum.—Root tuberous. Stem herbaceous, twining from left to right. Leaves alternate. Flowers small, axillary, racemose.—Ex. *Tamus*.

This order agrees in many points with *Smilacææ*, but differs by the adherent fruit. According to Mr Lindley, it makes a near approach in structure to the *Dicotyledones*, the leaves being those of that class, while the stem, flower, and seeds, are those of the *Monocotyledones*. The suborders are so closely allied that *Testudinaria*, till lately, was considered a species of *Tamus*.—The tubers or yams produced by *Dioscorea* are well known as an article of food in all tropical countries.

B.—ENDOGENÆ. D. C.

(13. Monoperigynæ. JUSS.)

13. Mono-perigynæ.

Order 182. *Bromeliaceæ*. JUSS.

Perianth tubular, six-cleft, in two rows: the outer persistent, the inner petaloid, marcescent or deciduous. Stamens six (rarely more), inserted into the base of the segments of the perianth. Ovarium either entirely free, or cohering more or less with the tube of the perianth, three-celled: ovules indefinite: style single: stigma three-parted, often twisted. Fruit capsular or succulent, three-celled. Seeds indefinite. Embryo cylindrical, recurved, lying in the base of a farinaceous albumen.—Plants, with

scarcely any stem. Leaves rigid, channelled, often thorny or toothed at the margin.—Ex. *Bromelia*, *Tillandsia*.

Sometimes the fruits in the same spike cohere together into a mass; by means of the perianth become succulent; and this is the structure of the pine-apple.—The pine-apple is well known. The *Agave Americana* is remarkable for the quick growth of its flower stalk, reaching sometimes to the height of thirty feet in ten days; and as its growth is most rapid at first, one may almost see its progress. The scape of several species, when withered, is cut into slices for razor strops, for which it is well adapted, on account of a very small portion of silica it is supposed to contain among the cellular substance. The fibres of the leaves of some of these species serve for making cordage.

Order 183. *Smilacææ*. R. BROWN.

Perianth petaloid, six-parted. Stamens six, inserted into the base of the divisions of the perianth, rarely hypogynous. Ovarium free, three-celled: ovules one or several in each cell: style usually three-cleft: stigmas three. Fruit a globose berry. Seeds with a membranaceous (neither black nor crustaceous) testa. Albumen fleshy, cartilaginous. Embryo often remote from the hilum.—Herbaceous or suffrutescent plants, often climbing. Leaves with the veins sometimes reticulated.—Ex. *Smilax*, *Paris*, *Convallaria*.

Between *Dioscoreæ* and *Asphodeleæ*, from which last it is principally distinguished by the testa of the seed.—The species are in general diuretic. The roots of *Trilium* are emetic.

Order 184. *Asphodelineæ*.

Suborder 1. *Asphodeleæ*. R. BROWN. Perianth petaloid, six-divided, regular. Stamens six, inserted upon the perianth, or hypogynous; the three opposite the outer segments of the perianth sometimes unlike the others, or wanting, anthers bursting inwardly. Ovarium free, three-celled, rarely apocarpous: ovules two ascending, or many, in each cell: style one: stigma entire, or shortly three-lobed. Fruit either a capsule, three-celled, three-valved, loculicide; or fleshy, and then sometimes tripartite. Seeds with a black, crustaceous, brittle testa. Embryo included in a fleshy albumen.—Herbaceous plants or trees. Leaves with parallel veins. Peduncles articulated at their middle or near the apex.—Ex. *Asphodelus*, *Scilla*, *Aloe*, *Asparagus*.

Suborder 2. *Gilliesiææ*. LINDL. Perianth six- (or, by the cohesion of the two outer anterior segments, five-) parted, in a double row: the outer herbaceous, the inner more coloured: estivation twisted. Stamens in a double series; outer sterile, forming either a six-toothed urceolus or three scale-like bodies, of which the anterior (*labellum*) is very dissimilar to the others; inner of six fertile stamens, or a six-toothed urceolus, of which the three anterior teeth alone bear anthers. Ovarium free, three-celled: ovules numerous: style one: stigma simple. Capsule three-celled, three-valved, loculicide. Seeds numerous: testa black and crustaceous. Embryo curved in the midst of a fleshy albumen.—Herbaceous plants with tunicated bulbs. Leaves grass-like. Flowers umbellate, arising from spathaceous bractæ.—Ex. *Gilliesia*, *Miersia*.

Gilliesiææ is a singular suborder; and even the view we have taken is neither that of Lindley nor Hooker. They regard our perianth as bracteal or involucreal leaves, and the outer row of stamens as the perianth; we consider the whole structure as elucidated by that of the *Amomeæ*. The inner row of the perianth appears at first sight to consist of only two of the parts, while the others seem external, but in estivation that series is formed of three of them. The outer series of stamens (sterile) has subulate appendages projected outwardly from the base. The As-

Arrange-
ment and
Characters.

phodelineæ are most certainly distinguished from their allies by the black brittle testa of the seed.—All species, at least of the Asphodeleæ, contain a bitter stimulant principle in a gummy viscid juice. The onion, leek, garlic, and their allies, belong to the genus *Allium*. The roots of several are purgative; the Aloes are well known for this property. Gum Dragon is the styptic juice of *Dracena Draco*.

Order 185. *Liliaceæ*. JUSS.

Perianth coloured, regular, six-divided. Stamens six, perigynous, opposite the segments of the perianth. Ovary free, three-celled: ovules indefinite: style one: stigma simple or three-lobed. Capsule three-celled, three-valved, loculicidal. Seeds numerous, usually flat, packed one above the other in one or two rows: testa spongy, dilated, often winged. Embryo straight, in the axis of a fleshy albumen: radicle next the hilum.—Plants with scaly bulbs or arborescent stems. Leaves with parallel veins.

Tribe 1. *Tulipeæ*. D. C. Perianth deeply divided.—Ex. *Lilium*, *Fritillaria*, *Erythronium*.

Tribe 2. *Hemerocallideæ*. R. BROWN. Perianth tubular.—Ex. *Hemerocallis*, *Polyanthes*.

Closely allied to the last order, and also to Melanthaceæ, through *Erythronium*. We can scarcely conceive why this last has been sometimes placed in Asphodeleæ; for the testa is brown and spongy, and not black and crustaceous. The roots of most of the species of *Lilium* found in the east of Siberia, particularly *L. spectabile*, *ternifolium*, and *Kamtschaticum*, are eaten like potatoes, and known by the name of Sarana (Саpаha, Russ.)

Order 186. *Melanthaceæ*. BATSCH.

Perianth petaloid, six-divided, the margin of the segments generally involute in estivation. Stamens six: anthers usually bursting outwards. Ovary three-celled: ovules numerous: style trifid or tripartite: stigmas three, undivided. Capsule three-celled, usually septicidal, sometimes loculicidal. Seeds with a membranous testa. Albumen dense, fleshy.—Leaves sheathing at the base, with parallel veins.—Ex. *Melanthium*, *Colchicum*, *Tofieldia*.

This order requires revision. The positive characters separating it from Liliaceæ, depending on the divided style, are slight.—Every species is poisonous, but particularly the genera *Colchicum* and *Veratrum*.

Order 187. *Pontederiaceæ*. KUNTH.

Perianth tubular, coloured, six-cleft, more or less irregular: estivation circinate. Stamens three or six, unequal, perigynous. Ovary free, or sometimes coherent at the base, three- (or rarely one-) celled: ovules indefinite: style one: stigma simple. Capsule three- (rarely one-) celled, three-valved, loculicidal. Seeds indefinite: testa membranous: hilum small. Embryo straight, in the axis of a somewhat farinaceous albumen: radicle next the hilum.—Aquatic or marsh plants. Leaves sheathing at the base: veins parallel.—Ex. *Pontederia*, *Heteranthera*, *Lepanthus*.

Distinguished from Asphodeleæ by the testa of the seed: the syncarpous ovary and perigynous stamens separate them from Alismaceæ.

Order 188. *Restiaceæ*. R. BROWN.

Suborder 1. *Restiæ*. Perianth 2-6-partite, sometimes wanting. Stamens definite, perigynous, 1-6; when half as many as the segments of the perianth they are opposite the inner divisions: anthers usually one-celled. Ovary one or more-celled: ovules solitary, pendulous. Fruit capsular or nucamentaceous. Seeds pendulous. Embryo lenticular, on the outside of a farinaceous albumen, at the extremity remote from the hilum.—Herbaceous or suffrutescent plants. Leaves simple, narrow, or none. Culms naked, or protected by sheaths, which are usually slit (en-

tire in *Eriocaulon* alone), with the one margin overlapping the other. Flowers in spikes or capitula, separated by bracteolæ or scales, and usually unisexual.—Ex. *Restio*, *Centrolepis*, *Elegia*, *Eriocaulon*.

Suborder 2. *Xyrideæ*. KUNTH. Perianth six-parted, in two rows; outer glumaceous; inner petaloid, unguiculate. Stamens six, three fertile inserted upon the apex of the claw of the segments of the inner row of the perianth: anthers bursting outwardly. Ovary single: ovules indefinite: style trifid: stigmas obtuse, multifid or undivided. Placentas three, parietal. Capsule one-celled, three-valved. Seeds numerous. Embryo on the outside of a farinaceous albumen, at the extremity remote from the hilum.—Herbaceous plants. Leaves radical, with dilated, equitant, scarious bases. Culms naked. Flowers in terminal capitula.—Ex. *Xyris*, *Abolhoda*.

Closely allied to Junceæ and also to Cyperaceæ, from which it is distinguished by the position of the embryo.—The leaves and roots of *Xyris Indica* are employed against the itch and leprosy. The tough wiry stems of *Willdenovia teres* and some others are manufactured into baskets and brooms.

Order 189. *Junceæ*. JUSS.

Perianth six-parted, more or less glumaceous. Stamens six, inserted into the base of the segments, sometimes only three and opposite the outer series: anthers two-celled. Ovary 1-3-celled: ovules one, three, or many, in each cell: style one: stigmas generally three, sometimes only one. Fruit capsular, three-valved, loculicidal, sometimes indehiscent. Seeds with a testa neither black nor crustaceous. Embryo inclosed within a firm, fleshy, or cartilaginous albumen, seated near the hilum.—Herbaceous plants. Leaves fistular, or channelled, or flat, with parallel veins.—Ex. *Juncus*, *Luzula*.

Related to the Restiaceæ and Asphodeleæ, as also to the Palmæ.—The leaves of *Flagellaria* are supposed to be astringent: the others have no particular medical properties. Different species of *Juncus* are used for making chair-bottoms, mats, &c., and the pith for the wicks of candles.

Order 190. *Palmæ*. JUSS.

Flowers bisexual or polygamous. Perianth six-parted, persistent, in a double row; the three outer segments often smaller, the three inner sometimes deeply connate. Stamens inserted into the base of the perianth, usually six, seldom three, in a few polygamous genera indefinite in number. Ovary one-three-celled, or deeply three-lobed: ovules three, rarely one. Fruit baccate or drupaceous, the flesh fibrous. Albumen cartilaginous, either ruminate, or furnished with a central or lateral cavity. Embryo cylindrical, or flat and circular, small, usually at a distance from the hilum, lodged in a lateral cavity at the opposite side from the empty cavity of the albumen.—Trunk arborescent, simple, occasionally shrubby and branched. Leaves terminal, large: vernation plaited. Spadix terminal, often branched; spathe one or many-valved.—Ex. *Sabal*, *Phoenix*, *Calamus*, *Borassus*, *Areca*, *Cocos*.

We have already said that there was a relation between this and the Junceæ. Pandanææ seems to have no affinity; but between *Calamus* and Gramineæ, particularly the bamboo, many points of comparison present themselves.—Wine, oil, wax, flour, sugar, salt, thread, utensils, weapons, habitations, and food, are obtained from this order. The cocoa-nut, sago, date, and betel-nut, are well known. The common cane that is imported is a species of *Calamus*. The name Coccineæ may be given to a "section whose principal character consists in the originally trilobular putamen having its cells, when fertile, perforated opposite to the seat of the embryo, and, when abor-

Arrangement and Characters.

Arrangement and Characters. tive, indicated by foramina 'cœca.'¹ From the fruits of this section only, the oil afforded by plants of this family is obtained.

B. ENDOGENÆ. D. C.

(14. Monohypogynæ. JUSS.)

14. Monohypogynæ.

Order 191. *Commelineæ*. R. BROWN.

Perianth in two rows; outer herbaceous, tripartite; inner petaloid, tripartite or trifid. Stamens six or fewer, hypogynous: anthers of some filaments either wanting or differently formed from the others. Ovarium three-celled: ovules few in each cell: style one: stigma one. Capsule 2-3-celled, 2-3-valved, loculicide. Seeds often in pairs in each cell: hilum usually linear and lateral. Albumen densely fleshy. Embryo flat and circular (pulley-shaped), lying in a cavity of the albumen, and at the opposite extremity from the hilum: radicle projected from the centre of the embryo.—Herbaceous plants. Leaves usually sheathing at the base.—Ex. *Commelina*, *Tradescantia*.

Not very closely allied to either Juncæ or Restiaceæ. With some Palmæ they agree in the singular embryo: this is flat and circular, and the radicle projects from its centre towards the outside of the seed, thus resembling a pulley and its axis: moreover, in both orders the embryo is remote from the hilum, the radicle pointing away from it, and its position being indicated by an external papilla.

Order 192. *Alismacæ*. R. BROWN.

Suborder 1. *Alismoideæ*. D. C. Perianth six-partite, in two rows; outer herbaceous, inner petaloid. Stamens definite or indefinite, hypogynous. Ovarium of several one-celled carpels, apocarpous: ovules erect or ascending, solitary in each ovary, or in pairs at a distance from each other: styles and stigmas several. Fruits of several dry, indehiscent carpels. Seeds 1-2 in each cell. Albumen none. Embryo cylindrical, curved like a horse-shoe: radicle next the hilum.—Floating plants. Leaves with parallel veins.—Ex. *Alisma*, *Sagittaria*.

Suborder 2. *Butomeæ*. RICH. Perianth six-parted, in two rows; outer usually herbaceous, inner petaloid. Stamens definite or indefinite, hypogynous. Ovarium of three, six, or more, one-celled carpels, apocarpous or syncarpous: ovules very numerous in each cell: stigmas simple, as many as the carpels. Placentas ramified over the inner surface of each carpel. Fruit of several follicles, distinct and rostrate, or cohering into one mass. Seeds minute, indefinite. Albumen none. Embryo straight, or curved like a horse-shoe: radicle next the hilum.—Aquatic plants. Leaves with parallel veins, often possessing a milky juice. Flowers in umbels.—Ex. *Butomus*, *Limncharis*.

Suborder 3. *Juncagineæ*. RICH. Perianth herbaceous, rarely wanting. Stamens six, hypogynous. Ovarium of three or six carpels, cohering firmly together: ovules one or two in each carpel, erect, approximated at their base. Fruit dry. Seeds 1-2, erect. Albumen 0. Embryo straight: radicle at the opposite extremity from the hilum: plumule emitted through a lateral cleft in the embryo.—Herbaceous bog-plants. Leaves ensiform: veins parallel. Flowers in spikes or racemes, minute.—Ex. *Triglochin*, *Scheuchzeria*.

The limits of this order are not perhaps yet well understood. According to Mirbel, the radicle in every embryo, curved like a horse-shoe, is actually at the apex, although by the curvature of the seed it may appear close to the hilum; and if this view be correct, Alismacæ ought to consist of Alismoideæ (to which might be attached *Limncharis* and the other genera of Butomeæ with a curved

embryo), with perhaps the addition of Potameæ; while *Butomus* and *Juncagineæ*, both with a decidedly orthotropous embryo, ought to be rejected. The apocarpous ovary of Alismoideæ makes this hold the same rank among the Monocotyledones that is done by Ranunculaceæ among the higher organized vegetables.—Alismoideæ and Butomeæ have an acrid herbage.

Order 193. *Pandaneæ*. R. BROWN.

Flowers unisexual or polygamous, wholly covering the spadix. Perianth 0. Filaments of the stamens with a single two-celled anther. Ovaria one-celled, united together in groups: ovules usually solitary, erect: stigma, one to each ovary, sessile, adnate. Fruit either fibrous drupes, collected several together, or baccate and plurilocular. Seeds in the drupes solitary, in the baccate genera several in each cell. Embryo in the axis of a fleshy albumen: radicle pointing to the hilum: plumula inconspicuous.—Stem arborescent. Leaves imbricated in three rows, long, amplexicaul, with the margin usually thorny.—Ex. *Pandanus*, *Freyinetia*.

Usually placed next the palms, but in reality much more nearly allied to Aroideæ (Typhaceæ), of which Kunth makes it a section.—The seeds of *Pandanus* are eatable, as well as the flowers of *P. odoratissimus*; the fruit of several is used as an article of food.

Order 194. *Aroideæ*. JUSS.

Suborder 1. *Typhaceæ*. D. C. Flowers unisexual, arranged upon a naked spadix. Perianth three-parted. Stamens three or six, opposite to the segments of the perianth: filaments long and slender: anthers wedge-shaped, erect, bursting outwardly. Ovarium single, free, one-celled: ovule solitary, pendulous: style short: stigmas one or two, linear, simple. Fruit dry, indehiscent, one-celled. Embryo in the centre of a farinaceous albumen, straight, cylindrical: radicle next the hilum: cotyledon cylindrical, with a short longitudinal lateral cleft near its base: plumule of 2-3 leaves, the outer contained in the cleft of the cotyledons, and partly protruded.—Herbaceous marsh plants. Stems without nodi. Leaves sheathing at their base, rigid, ensiform, with parallel veins.—Ex. *Typha*, *Sparganium*.

Suborder 2. *Arineæ*. Flowers uni-, rarely bisexual, arranged upon a spadix, often naked. Perianth 4-6-partite, or wanting. Stamens definite and opposite the lobes of the perianth, or indefinite, hypogynous: filaments very short: anthers 1-2- or many-celled, ovate, bursting outwardly. Ovarium free, one-celled, rarely three-celled: ovules several, rarely solitary, ascending, peritropal, or rarely pendulous: stigma sessile. Fruit succulent or dry, indehiscent. Seeds solitary or several. Embryo in the axis of a fleshy or farinaceous albumen (which is rarely wanting), straight, cylindrical: radicle next the hilum, rarely at the opposite extremity: cotyledon cylindrical, with a short lateral cleft near its base: plumule 2-3-leaved, the outer leaf contained in the cleft of the cotyledon, and partly protruded.—Herbaceous or suffrutescent plants. Root often tuberous or thickened. Leaves sheathing at the base, with parallel or branching veins, often cordate, entire, or sometimes divided. Spadix usually inclosed in a spatha.—Ex. *Arum*, *Caladium*, *Pothos*, *Acorus*.

Suborder 3. *Pisticeæ*. RICH. Flowers unisexual, inclosed in the same spatha. Stamens definite, 2-7, in a spatha. Ovarium one in each spatha, one-celled: ovules two or several, erect or horizontal: style short: stigma simple. Fruit membranous, one-celled, indehiscent. Seed one or several: testa thick and spongy: chalaza thick, adhering to the apex of the cotyledon, and separable from the integuments. Embryo either large in the axis of a

¹ Brown, in Tuckey's *Voyage*, p. 456.

thin and fleshy albumen, with a lateral cleft for the emission of the plumule; or minute at the extremity of a copious farinaceous albumen, most remote from the hilum: radicle pointing to the hilum.—Floating plants. Flowers appearing from the margin of the stems.—Ex. *Pistia*, *Lemna*.

We continue to unite these suborders. The difference between the two first is reduced to the structure of the stamens, for the same number and position of the ovules occurs in both. As to *Pistia*, there is as great a difference between its constituent genera as betwixt either and the true Aroideæ. It is difficult to determine the position of the radicle in *Pistia*; but as the inner integument (tegmen) of the seed is pendulous in the ovule, we are forced to suppose that the radicle points to the hilum, although the embryo itself is at the other extremity, a structure very uncommon. What we suppose the chalaza, Mr Lindley, however, describes as an indurated foramen, and consequently, in both *Lemna* and *Pistia*, the radicle would be turned away from the hilum; but this structure our own observations on *Pistia* do not confirm. The apex of the seed, however, in that genus has a strong depression, or orifice, caused by the separation of the chalaza, and its attachment to the apex of the embryo.—All the Aroideæ are acrid; and this principle is sometimes so strong as to render various species very poisonous. The flat underground stems, and the leaves of many, are however harmless, and, when boiled or roasted, are even nutritive.

Order 195. *Potamææ*. Juss.

Flowers bi- or unisexual. Perianth two or four-parted, often deciduous, sometimes wanting. Stamens definite, hypogynous. Ovarium one or more, free, inserted on the receptacle or central spadix: ovule solitary in each ovary: style one or none: stigma one, entire or rarely two- or three-parted. Fruit dry, indehiscent, one-celled. Seed solitary, pendulous, or suspended. Albumen 0. Embryo straight or curved, with a lateral cleft for the emission of the plumule: radicle very large, inferior, pointing to the extremity remote from the hilum.—Water plants. Leaves very cellular, with parallel veins. Flowers minute.—Ex. *Potamogeton*, *Najas*, *Zostera*.

The structure of the seed of *Zostera* is explained by that of *Ruppia*, where the great mass of the embryo is the radicle with a cleft for the emission of the plumule. If we suppose, with Richard, that in no case is the flower of *Potamææ* bisexual, but that even in *Potamogeton* the perianth is a four-partite spatha, we shall readily see how closely this order approaches to the Aroideæ.—Of little use. *Zostera* is used for packing, and stuffing the beds of the poorer classes.

Order 196. *Podostemææ*. Rich.

Flowers naked, bisexual, bursting through an irregularly lacerated spatha. Stamens hypogynous, definite or indefinite, monadelphous, alternately sterile and shorter. Ovarium free, spuriously two-celled: ovules numerous: styles two or none: stigmas two or three. Placenta forming the dissepiment. Fruit slightly pedicellate, capsular, two-valved, septicide, the valves falling off from the dissepimental placenta. Seeds indefinite, minute.—Herbaceous, branched, floating plants. Leaves capillary or linear, or irregularly lacerated, or minute and imbricated. Flowers minute.—Ex. *Podostemum*, *Lacis*, *Mniopsis*.

The internal structure of the seed is still unknown. Martius says it is homogeneous; but we may rather compare them with the seeds of such *Potamææ* as consist almost entirely of an immense radicle; and there are many other points of resemblance between the two orders. Mr Lindley arranges *Podostemææ* between *Piperacææ* and *Callitrichinææ* (Haloragææ).—No properties are known.

Order 197. *Cyperacææ*. Juss.

Flowers bi- or unisexual, furnished each with a soli-

itary bracteole called a *glume* or *scale*, which are imbricated on a common axis. Perianth rarely membranaceous, 2-3-valved, the valves distinct or united: generally entirely wanting. Stamens hypogynous, definite (1-12), with sometimes an additional row of abortive filaments or *setæ*: anthers erect, two-celled: ovary one-celled: ovule one, erect: style single, three-cleft or bifid: stigmas undivided, or occasionally bifid. Fruit an achenium or nut. Embryo lenticular, seated at the base of a farinaceous albumen, and covered by a very thin membranous projection of it: plumule inconspicuous.—Roots fibrous. Stems often without joints. Sheaths of the leaves entire.—Ex. *Cyperus*, *Scirpus*, *Scleria*, *Carex*.

We have slightly altered the character of the order from that usually given; for while we consider *Carex* and some others to have a true perianth, we cannot regard the hypogynous *setæ* of authors in the same light, they being more analogous to abortive stamens, and consequently to a corolla. The *Cyperacææ* are closely allied to the *Graminææ*.—The herbage of this order contains almost no nutritive principle. The roots of some are succulent, and possess diaphoretic and demulcent properties: those of *Cyperus esculentus* are said to be eaten; those of *Cyperus longus* are bitter and tonic; those of *Cyperus odoratus* have a warm aromatic taste. The *Cyperus Papyrus* yielded the paper of the Egyptians. Some species of *Scirpus* are used for making chair bottoms.

Order 198. *Graminææ*. Juss.

Flowers usually bisexual, sometimes unisexual or polygamous; one, two, or more being seated on a common rachis, which is contained within an involucre, that consists of one or two valves (*glumes*), or is rarely wanting; the whole constituting a *locusta*. Partial involucre similar to the glumes, of two (rarely one) dissimilar valves (*glumellæ* or *paleæ*); outer or lower simple, usually carinate: inner with two nerves or keels, and hence formed of two pieces cohering by their contiguous margins. Lodicule (abortive stamens?) of two (rarely one) hypogynous minute scales, sometimes wanting. Stamens hypogynous, 1-6, or rarely indefinite: anthers two-celled, versatile: ovary simple: ovule one: style one, bipartite, rarely simple or tripartite: stigmas plumose or hairy. Pericarp a caryopsis. Albumen farinaceous. Embryo lenticular, external, lying on one side of the albumen near its base.—Culms cylindrical, hollow, jointed. Leaves alternate: sheath split. Locustæ of flowers arranged in spikes, racemes, or panicles.—Ex. *Panicum*, *Avena*, *Anthoxanthum*.

The above, with some slight variations, is the account of the structure of these plants most usually adopted. Some botanists term the partial involucre the perianth, others view the lodicule in that light; perhaps if a perianth be present, it must be looked for in the upper glumella alone. Their affinity with *Cyperacææ* is evident.—This order, whether as furnishing food to man or beast, is one of the most important in the whole vegetable kingdom. Wheat, barley, oats, rice, guinea corn, millet, maize, and the sugar-cane, belong to it. The cuticle contains a large quantity of silex. This abounds so much in the sugar-cane, that by the mere using that plant for fuel in the extraction of sugar, the fire-place is soon choked up by large masses of a coarse kind of glass. The siliceous matter of the bamboo is often secreted at the diseased joints, and forms the mineral called Tabasheer. The straw of different grasses is plaited, and made into ladies' bonnets: that used at Leghorn is the *Hordeum pratense*, which also grows wild in our own country. Seringe's *Herbarium Cereale*, with the accompanying descriptions in his *Malanges Botaniques*, deserve to be carefully studied by such as principally attend to the uses of this tribe of plants,

Arrangement and Characters.

ledones.
§ 1. Duc-
tulosæ.

II.—CELLULARES. D. C.

(15. ACOTYLEDONES. JUSS. § 1. DUCTULOSÆ.¹)

Order 199. *Equisetaceæ*. D. C.

Sporules surrounded by elastic clavate filaments, and inclosed in thecæ arising from the scales of terminal cones.—Vernation straight.—Ex. *Equisetum*.

The cuticle abounds in silex, and hence the plants of the only genus of this order are very useful for polishing furniture, &c.

Order 200. *Filices*. JUSS.

Sporules inclosed in thecæ arising from the back or margin of the fronds, or rarely without thecæ seated on the back of a deformed frond (LINDL.).—Vernation circinate, in those without thecæ straight.—Ex. *Polypodium*, *Gleichenia*, *Osmunda*, *Danæa*, *Ophioglossum*, *Parkeria*.

Adopting Mr Lindley's views already explained relative to the formation of the thecæ of ferns, he is led to the conclusion that *Ophioglossum* and its allies have no thecæ, but that what is there called so are merely the involute contracted segments of the deformed frond that bears the sporules.—The fronds generally contain an astringent mucilage, and are thus considered as pectoral and lenitive. A few species have been employed for food. The caudex of *Aspidium Filix mas*, and *Pteris aquilina*, being bitter and astringent, have been used as anthelmintics, emmenagogues, and purgatives. *Aspidium fragrans* has been employed as a substitute for tea.

Order 201. *Marsiliaceæ*. R. BROWN.

Sporules inclosed in thecæ which are contained within closed involucre.—Ex. *Marsilea*, *Salvinia*.

Their properties are entirely unknown.

Order 202. *Lycopodiaceæ*. SWATZ.

Sporules inclosed in axillary thecæ.—Vernation circinate.—Ex. *Lycopodium*, *Isotetes*.

The minute pulverulent matter contained in the one kind of thecæ is highly inflammable, and is collected on the continent in considerable quantities, particularly from *Lycopodium clavatum*. It is used for artificial lighting in the theatres. *Lyc. clavatum* and *L. Selago* excite vomiting.

II.—CELLULARES. D. C.

(15. ACOTYLEDONES. JUSS. § 2. EDUCTULOSÆ.)

Order 203. *Musci*. JUSS.

Sporules contained in thecæ closed by an operculum or lid, which falls off or is rarely adnate.—Stem with leafy appendages.—Ex. *Hypnum*, *Gymnostomum*, *Andræa*.

Of little or no use, except for packing.

Order 204. *Hepaticæ*. JUSS.

Sporules contained in thecæ which are dehiscent (or rarely indehiscent), and destitute of an operculum.—Plants with leafy appendages.—Ex. *Marchantia*, *Jungermannia*.

Some species are slightly fragrant, but little is known of their properties.

Order 205. *Algæ*. JUSS.

Plants without leafy appendages, and with very few exceptions found in water. Sporules variously disposed.—Ex. *Fucus*, *Ulva*, *Conferva*, *Chara*.

The *Hæmatococcus nivalis*, or red snow plant, belongs to this order.—The algæ are of considerable importance in our manufactures and domestic economy. "*Rhodomenia palmata*, the dulce of the Scots, dilleek of the Irish,

and saccharine *Fucus* of the Icelanders, is consumed in considerable quantities throughout the maritime countries of the north of Europe, and in the Grecian archipelago; *Iridæa edulis* is still occasionally used both in Scotland and the south-west of England. *Porphyra laciniata* and *vulgaris* is stewed, and brought to our tables as a luxury under the name of Laver, and even the *Ulva latissima*, or green Laver, is not slighted in the absence of the *Porphyra*. *Enteromorpha compressa*, a common species on our shores, is regarded, according to Gaudichaud, as an esculent by the Sandwich islanders. *Laurentia pinnatifida*, distinguished for its pungency, and the young stalks and fronds of *Laminaria digitata* (the former called Pepperdulse, the latter Tangle) were often eaten in Scotland; and even now, though rarely, the old cry, 'buy dulse and tangle,' may be heard in the streets of Edinburgh. When stripped of the thin part, the beautiful *Alaria esculenta* forms a part of the simple fare of the poorer classes of Ireland, Scotland, Iceland, Denmark, and the Faroe Islands. To go farther from home, we find the large *Laminaria pottorum* of Australia furnishing the Aborigines with a proportion of their instruments, vessels, and food. On the authority of Bory St Vincent, the *Durvillea utilis* and other *Laminariæ* constitute an equally important resource to the poor on the west coast of South America. In Asia several species of *Gelidium* are made use of to render more palatable the hot and biting condiments of the East. Some undetermined species of this genus also furnish the materials of which the edible swallows' nests are composed. It is remarked by Lamaroux that three species of swallow construct edible nests, two of which build at a distance from the sea coast, and use the sea-weed only as a cement for other matters. The nests of the third are consequently most esteemed, and sold for nearly their weight in gold. *Gracillaria lichenoides* is highly valued for food in Ceylon and other parts of the East, and bears a great resemblance to *G. compressa*, a species recently discovered on the British shores, and which seems to be little inferior to it. It is not to mankind alone that marine Algæ have furnished luxuries or resources in times of scarcity. Several species are greedily sought after by cattle, especially in the north of Europe. *Rhodomenia palmata* is so great a favourite with sheep and goats, that Bishop Gunner named it *Fucus ovinus*. In some of the Scottish islands, horses, cattle, and sheep, feed chiefly upon *Fucus vesiculosus* during the winter months; and in Gothland it is commonly given to pigs. *Fucus serratus* also, and *Chorda Filum*, constitute a part of the fodder upon which the cattle are supported in Norway. In medicine we are not altogether indebted to the Algæ. The *Gigartina helminthocorton*, or Corsican moss, as it is frequently called, is a native of the Mediterranean, and held once a considerable reputation as a vermifuge. The most important medical use, however (omitting minor ones), derived from sea-weeds, is through the medium of Iodine, which may be obtained either from the plants themselves or from kelp. French kelp, according to Sir H. Davy, yields more Iodine than British; and, from some recent experiments made at the Cape of Good Hope by M. Ecklon, *Laminaria buccinalis* is found to contain more than any European Algæ. Iodine is known to be a powerful remedy in cases of goitre. But were the Algæ neither 'really serviceable either in supplying the wants, or in administering to the comforts, of mankind' in any other respect, their character would be redeemed by their usefulness in

¹ De Candolle arranges these, as has already been seen, among the Endogenæ; we have stated our reasons for their removal here. The structure of each order of the Cellulares we have already described at sufficient length, and shall therefore refer to p. 37 and p. 53.

Ex. the arts; and it is highly probable that we shall find ourselves eventually infinitely more indebted to them. One species (and I regret to say that it is not a British one) is invaluable as a glue and varnish to the Chinese. This is the *Gracillaria tenax*, the *Fucus tenax* of Turner's *Historia Fucorum*. Though a small plant, the quantity annually imported at Canton from the provinces of Tokien and Tchekiang is stated by Mr Turner to be about 27,000 pounds. It is sold at Canton for 6d. or 8d. per pound, and is used for the purposes to which we apply glue and gum-arabic. The Chinese employ it chiefly in the manufacture of lanterns, to strengthen or varnish the paper, and sometimes to thicken or give a gloss to silks or gauze. In addition to the above account, the substance of which I have extracted from Mr Turner's work, Mr Neill remarks that 'it seems probable that this is the principal ingredient in the celebrated gummy matter called Chin-chow, or Hai-tsai, in China and Japan. Windows made merely of slips of bamboo, crossed diagonally, have frequently their lozenge-shaped interstices wholly filled with the transparent gluten of the Hai-tsai.' On the southern and western coasts of Ireland, our own *Chondrus crispus* is converted into size for the use of the house-painters, &c., and, if I be not erroneously informed, is also considered as a culinary article, and enters into the composition of blanc-mange, as well as other dishes. In the manufacture of kelp, however, for the use of the glass-maker and soap-boiler, it is that the Algæ take their place among the most useful vegetables. The species most valuable for this purpose are, *Fucus vesiculosus*, *nodosus*, and *serratus*; *Laminaria digitata* and *bulbosa*; *Himanthalia lorea*, and *Chorda Filum*.¹

Order 206. *Lichenes*. Juss.

Plants not growing in water, without leafy appendages. Sporules lying in superficial disc.—Ex. *Parmelia*, *Ramalina*.

Some Lichens were formerly supposed to grow in water. This is still allowed by Fries, but he denies that they ever fructify there; and he has further observed, that several of what were termed Algæ, upon being removed from that element and exposed to the sun, produce shields and become Lichens. "Lichens," says De Candolle, "present two classes of properties, 1st, the dyeing properties, which are developed by different agents, and especially by maceration in urine, properties which are common to all the species, but particularly to such as approach most to the consistence of a calcareous crust; 2d, medicinal properties, which are most sensible in those species that are soft, whether it be that these contain more mucilage, or that they have been most experimented upon." The Iceland moss of the shops, which is the *Cetraria Islandica*, is tonic, demulcent, and nutrient; and several others are nearly equally suited to the same purpose. The Orchale or Archill, and Cudbear, of various kinds, are all famed for the dye they give out.

Order 207. *Fungi*. Juss.

Plants not growing in water, and without leafy appen-

dages. Sporules in the substance of the plants, the whole of which may be viewed as organs of reproduction.—Ex. *Sphæria*, *Agaricus*, *Lycoperdum*, *Mucor*, *Uredo*.

This order presents many anomalies. Some are wholesome, others extremely poisonous; nor does this diversity of property seem at all connected with their external forms, many most allied in appearance being extremely distinct in their virtues; and the difficulty of distinguishing the two kinds is known by all who have turned their attention to the subject. In this country, therefore, scarcely more than one or two mushrooms are eaten; in France, Italy, and Germany, more are used; and in Russia many are employed which are elsewhere considered as poisonous. Either the climate or the mode of cooking must thus operate in rendering these wholesome. The dry rot is caused by several species of parasitical Fungi, as *Polyporus destructor*, *Merulius vastator* and *lacrymans*, &c. The blights in corn, mildew, smut, and ergot, are also Fungi of the same description. Mouldiness, whether in cheese or on books, is also constituted of small parasitical Fungi, and is best prevented by the presence of an essential oil. Amadou or German tinder is prepared from some kinds of *Boletus* (as *B. ignarius* and *fomentarius*), and afterwards impregnated with nitre.

We have now presented an account of all the natural General orders of plants acknowledged up to the present time; and, on studying their characters, we are forced to draw the following conclusions. 1. That the difference between an ovary free, or adherent with the tube of the calyx, is weakened by many genera, as by comparing the Loasææ with the allied family of Turneraceæ, and by the genera of Dip-

saceæ, in which the ovary is adherent at the apex and not below. 2. The difference between hypogynous and perigynous stamens is often imperceptible, this depending on the greater or less expansion of the torus: the same may be said of the epigynous and gynandrous insertions. 3. Loculicide or septicicide dehiscence of the fruit depends only on the greater or less adhesion of the sides, or of the middle of the valves; both, in certain states, being liable, to dehisce. 4. The parietal placenta is merely that modification of the other kind in which the introflexed margin of the valves is little apparent. 5. Petals may be accidentally more or less combined by their margins into a gamopetalous corolla, or may be entirely absent; so that there is no limit between gamopetalous, polypetalous, and apetalous orders. 6. Stamens may be more or less combined, or distinct. 7. Stamens may become abortive, and even change into petals. 8. St Hilaire has shown that there are many ambiguous states in the relative positions of the radicle of the embryo and the hilum of the seed.

Thus the great characters for defining natural orders are impaired. To none in particular can we trust at all times; and it is only by a combination of several tolerably constant ones that, in the present state of our knowledge, we can attain that most desirable end of botanical classification, the natural approximation of genera. (U. U.)

Botticelli.

BOTANY BAY, a spacious bay on the south-east coast of New Holland, so named by Captain Cook, by whom it was discovered in 1770, from the profusion of hitherto unknown plants growing on its shores. Great Britain has established a settlement here for transported criminals. The bay does not afford either good shelter or anchorage, the water being too shallow for large vessels, which must remain exposed to all the dangers of an open road; and on this account the British settlement, though it still retains the name of Botany Bay, is at some miles distance. See AUSTRALASIA, and WALES, NEW SOUTH.

BOTANOMANCY (from *βοτανη*, an herb, and *μαντια*, divination), an ancient species of divination, by means of plants, especially of sage and fig leaves. The manner of performing it was this: The persons who consulted wrote their own names and their questions on leaves, which were exposed to the wind; and as many of the letters as remained in their own places were taken up, joined together, and considered as an answer to the question.

BOTH, JOHN and ANDREW, Flemish painters, and pupils of Bloemart, were born at Utrecht about the year 1610.

The union of these brothers was remarkable; they were alike inseparable in their studies, their travels, and their painting. John painted the landscape part of their pictures in the manner of Claude Lorrain, and Andrew drew the figures and animals in the style of Bamboche. They both died in 1650; Andrew having been drowned at Venice, and his brother John, through grief, having soon afterwards followed him to the grave. In the national gallery of France there is a painting by these two masters representing a *View of Italy at Sunset*.

BOTHNIA. See RUSSIA.

BOTTICELLI, ALESSANDRO, born at Florence in 1437, learned the rudiments of painting under Filippo Lippi. He executed several pictures for Pope Sixtus IV. and for the city of Florence, for which he received large sums of money; but he expended all his acquisitions in thoughtless extravagance, and at last died in great distress, aged seventy-eight. He was not only a painter, but a man of letters. Baldini, according to the general report, communicated to him the secret of engraving, then newly discovered by Finigucrra, their townsman. The famous edition

Bottle
li
Bottrigari.

of Dante's *Inferno*, printed at Florence by Nicholo Lorenzo della Magna in 1481, and to which, according to some authors, Botticelli undertook to write notes, was intended to have been ornamented with prints, one for each canto; and of these prints, as many as were finished were designed, if not engraved, by Botticelli. It is remarkable that the two first plates only were printed upon the leaves of the book, and, for want of a blank space at the head of the first canto, the plate belonging to it is placed at the bottom of the page. Blank spaces are left for the rest, that as many of them as were finished might be pasted on. The two first, as usual, are printed on the leaves; while the others, seventeen in number, which follow regularly, are pasted on the blank spaces; and these, apparently, were all that Botticelli ever executed. About the year 1460 he is said to have engraved a set of plates, representing the *Prophets and Sibyls*. Basan tells us that he marked these plates with a monogram composed of the two first letters of the alphabet joined together.

BOTTLE, a small vessel for containing liquors, and made of leather, of glass, or of stone. The word is formed from *butellus* or *botellus*, a barbarous Latin word for a small wine vessel; and a diminutive of *bota*, which denoted a but or cask of that liquor. The ancient Jewish bottles were made of the skins of goats or other wild beasts, with the hair on the inside, well sewed and pitched together; and an aperture in one of the paws served for the mouth of the vessel. Bottles are now chiefly made of thick coarse glass; but bottles of boiled leather are likewise made and sold by the case-makers. Fine glass-bottles, covered with straw or wicker, are called *flasks* or *bettees*. The quality of the glass has sometimes been found to affect the liquor in the bottle.

BOTTOM, in a general sense, denotes the lowest part of a thing, in contradistinction to the top or uppermost part.

BOTTOM, in *Navigation*, is used to denote as well the channel of rivers and harbours, as the body or hull of a ship. Thus, in the former sense, we say, *gravelly bottom*, *clayey bottom*, *sandy bottom*, and so forth; in the latter, a *British bottom*, a *Dutch bottom*, and the like.

BOTTOMRY, *fenus nauticum*, is a term applied to that particular kind of transaction where a person lends money to a merchant, who wants it to traffic, and is to be paid a greater sum at the return of a certain ship, standing to the hazard of the voyage; and, in this case, although the interest be greater than that allowed by law, it is not usury.

BOTTONY. A cross bottony, in *Herakdry*, terminates at each end in three buds, knots, or buttons, resembling in some measure the three-leaved grass; on which account Segoie, in his *Trésor Heraldique*, terms it *croix trefflée*. It is the badge of the order of St Maurice.

BOTTOSCHANY, a city of the province of Moldavia, in European Turkey. It is situated on a river of the same name, which falls a little below into the Siena. It consists chiefly of wooden houses, and has several Greek churches and monasteries, with 4200 inhabitants, who have a considerable trade in wine, cattle, wool, honey, wax, and tobacco. During the continental system the Jews and Armenians of Bottoschany carried on a great smuggling trade in sugar, coffee, and other colonial goods, with Brody, Leipsic, and Brunn.

BOTTRIGARI, HERCOLE, a person eminently skilled in the science of music, though not a musician by profession, was descended of a noble family of Bologna, and born in that city in the year 1531. He seems to have entertained a strong predilection in favour of the ancient music; and he attempted, as Vincentine and others had done, to introduce the chromatic scale into practice, but with no better

success than had attended the endeavours of his predecessors. He corrected Gogavino's Latin version of Ptolemy in numberless instances, and to so good purpose, that Dr Wallis has in general conformed to it in the translation of the same author, which he gave to the world many years afterwards. He also translated into Italian *Boetius de Musica*, with as much of Plutarch and Macrobius as relates to music; and besides this, he made annotations upon Aristoxenus, Franchinus, Spataro, Vicentino, Zarlino, Galislei, and, in short, on almost every musical treatise he could lay his hands on, as appears by the copies once belonging to him, which are now deposited in many libraries in Italy. Bottrigari's works contain greater proofs of his learning and skill in music, than of his abilities as a writer, his style being remarkably inelegant. Nevertheless, he affected the character of a poet; and there is extant a collection of poems by him, in 8vo, printed in 1557. Walther represents him as an able mathematician, and a collector of curiosities; and says that he was possessed of a cabinet which the emperor Ferdinand II. had a great desire to purchase. He died in 1612, and not in 1609, as stated by Mazzuchelli. From what has been said, a general idea may be formed of his works, a small portion of which only has been printed, and a correct list cannot now be obtained.

BOTTS. See ENTOMOLOGY, *Index*.

BOTZEN, a city, the capital of the circle of the Etsch, in the Austrian province of Tyrol. It is situated at the junction of the rivers Isach and Talfer, on the road from Germany to Italy, with both of which countries great commerce is carried on at four large fairs held annually here. It was destroyed by fire during the hostilities of 1809, but is now rebuilt, and contains about 4000 inhabitants. There are some considerable silk manufactories in the city. Long. 12. 3. E. Lat. 46. 47. 30. N.

BOUCHE OF COURT, the privilege of having meat and drink at court scot-free. This privilege is sometimes only extended to bread, beer, and wine. It was a custom anciently in use, as well in the houses of noblemen as in the king's court. Thomas earl of Lancaster retained Sir John de Ewre to serve him with ten men at arms in time of war, allowing them *bouche of court*, with livery of hay and oats, horse-shoes and nails. Sir Hugh Merrill had the same privilege for life, on condition of serving King Edward II.

BOUFLERS, LOUIS FRANCIS, DUKE OF, a peer and marshal of France, and a general of distinguished reputation, was the son of Francis count of Bouflers. He was born on the 10th January 1644, and having early entered into the army, was raised in 1669 to the rank of colonel of dragoons. In the conquest of Lorraine he served under Marshal Crevin. In the war against Holland he served under Turenne, frequently distinguishing himself by his skill and bravery; and when that celebrated captain was killed by a cannon-shot in 1675, he commanded the rear-guard during the retreat of the French army. After performing various military services in Germany, in Flanders, and on the frontiers of Spain, he gradually rose in rank as well as in reputation. In 1690 he was created general of the army of the Moselle, and contributed materially to the victory of Fleurus. In the following year he acted as lieutenant-general under the king in person; and whilst investing Mons, he was wounded in an attack on that place. He conducted the bombardment of Liege, although it was defended by an enemy superior in numbers, and afterwards forced the allied generals to abandon Luxembourg. He was intrusted with the command against King William at the siege of Namur; and for this and other important services he was raised, in 1693, to the rank of marshal of France. In 1694 he was appointed governor of French Flanders,

again-
file. and of the town of Lisle. By a skilful manœuvre he threw himself into Namur in 1695, and held out with unexampled obstinacy against the army of the allies under King William, sustaining four assaults, and only surrendering the place after four months of open trenches and the loss of 20,000 men to the besiegers. Having agreed to a capitulation, he was arrested as prisoner of war, because the French had not performed the stipulated terms on which the garrison had surrendered; and when he represented that the garrison should have been retained rather than himself, he was answered that he was estimated as worth more than 10,000 men. In the conferences which were held with the Earl of Portland, and terminated in the peace of Ryswick, he had a principal share. During the following war, when Lisle was again threatened with a siege by the Duke of Marlborough and Prince Eugene, Boufflers was appointed to the command, and made an obstinate resistance of four months. His magnanimity was not less remarkable than his military conduct; for when a partizan represented to him that it would not be difficult to kill Prince Eugene, he was told by the marshal, that he might expect a great reward for taking him prisoner, but the severest punishment if any thing were attempted against his life. He was rewarded and honoured by the king for his defence of Lisle, as if he had been victorious. It was indeed a species of triumph. His generous enemy, appreciating his merits, allowed him to dictate his own terms of capitulation: "je signerai," said Prince Eugene, "tout ce que vous voudrez;" and he was as good as his word. "Après quatre mois de tranchée ouverte," adds the prince in his *Mémoires*, "Boufflers m'envoya, le 8 décembre 1708, tous les articles qu'il voulait que je signasse; ce que je fis sans restriction." When the affairs of France were threatened with the most urgent danger, Boufflers, though a senior officer to Villars, made an offer to serve under that general, and was with him at the battle of Malplaquet. Here he again displayed his military skill by conducting the retreat, so that he lost neither cannon nor prisoners. He died at Fontainebleau in the year 1711, at the age of sixty-eight, and left the character of a true patriot, as well as of a great commander. Madame de Maintenon said of him, that "his heart was the last part that died."

BOUGAINVILLE, LOUIS ANTOINE DE, a celebrated circumnavigator, was born in Paris in 1729. His father was a notary and one of the sheriffs of the city of Paris. The parents of young Bougainville wished him to practise as a lawyer, and, for this purpose, he was received advocate in the parliament of Paris; but his own inclination was averse to the profession, and he entered into the army in the corps of musketeers.

He associated much with Clairaut and D'Alembert, who happened to live in his neighbourhood; and from this intercourse he derived his knowledge of algebra and fluxions. At the age of twenty-five he published his treatise on the *Integral Calculus*, intended as a supplement and continuation of L'Hôpital's treatise *Des infiniment petits*. Bougainville, in his preface, declares that all he has done in this work is to place in a systematic order the formulæ of different mathematicians.

He was raised to the rank of major in the Picardy regiment. He went to London as secretary to the French embassy, and was chosen a member of the Royal Society. In 1756 he went to Canada as captain of dragoons, and having distinguished himself in the war against England, was rewarded with the cross of the order of St Louis.

After the peace, the French government having conceived the project of planting a colony on the Falkland Islands, Bougainville undertook to begin this establishment at his own expense. The Falkland Islands, to which

Bougainville gave the name of Malouines (that is, St Malo Islands), are in 51° south latitude, and 10° of longitude to the east of the meridian of Cape Horn. Fish is abundant on their shores, and there is peat or turf for fuel, but no wood. Bougainville began the settlement by landing some families of French Canadians. The number of settlers was increased afterwards to 150.

This colony excited the jealousy of the Spanish government; and the government of France agreed that it should be given up to the Spaniards, the Spanish government undertaking to indemnify Bougainville for the expense he had been at in forming the establishment.

As a consolation to Bougainville for the loss of his colony he was appointed to command the frigate *La Boudese* of twenty-six eight pounders, and the transport *L'Etoile*, to go on a voyage of discovery round the world. He took with him Commerçon as naturalist, and Verron as astronomer.

This was the first voyage round the world performed by the French. Since the first circumnavigation by Magellan under the Spanish government in 1519, and that of Drake under Queen Elizabeth in 1577, eleven other circumnavigations of the world had been performed, part of them by the Dutch and part by the English, and also several voyages of discovery had been made in the Pacific Ocean without circumnavigation.

The expedition commanded by Bougainville was at Buenos Ayres at the time of the seizure of the Jesuits of Paraguay. The missions on the river Araguay, in the province of Paraguay, contained a population of 300,000 Indians, divided into parishes, and governed solely by the Jesuit parish priests. No other Europeans but the Jesuits were admitted into the country, in order that the work of conversion might not be frustrated by bad example. The produce of the labour of the Indians was delivered into the hands of the Jesuits, who furnished them with food and clothing. For this purpose the Jesuits had warehouses filled with European and American merchandise, and also a number of slaves. They had schools for instructing the Indians in music, painting, and other arts. The Spanish government having determined on the suppression of the Jesuits, took every precaution to prevent their being informed of the intended measure; and they were arrested and sent to Europe without any attempt at resistance on their part.

Bougainville passed the Straits of Magellan, and anchored for a week at Otaheite, where the English navigator Wallis had touched eight months before. A young man of Otaheite joined the expedition, and was taken to Paris, where he staid thirteen months. On his way back to his native country he died of the small-pox.

The numerous rocks and other dangers made Bougainville turn off to the north-east, and prevented him from continuing a westerly course, so as to pass through the channel which separates New Holland from New Guinea. These two islands, in his general chart, are laid down as forming one, although he possessed some information of the existence of the channel. Two years after, namely in 1770, Captain Cook sailed through this channel, so dangerous by its coral reefs.

The expedition having now crossed all the meridians of the Pacific Ocean, and suffering from the scurvy in consequence of scarcity of food, came to anchor in the Gulf of Cajeli, a settlement of the Dutch East India Company in the agreeable island of Borou, one of the Moluccas. The governor liberally supplied the wants of the expedition. He lived splendidly in a house built in the Chinese style, and judiciously adapted to the warmth of the climate; his wife and daughters wore the Chinese dress. "Sa maison étoit la notre," says Bougainville; "à toute heure on y

Bougainville.

Bougainville's Island.

trouvoit à boire et à manger, et ce genre de politesse en vaut bien un autre pour qui surtout se ressentoit encore de la famine." It was the beginning of September, and the expedition shortened their stay at Borou, in order to take advantage of the latter part of the easterly monsoon, which carried them to Batavia; from thence they proceeded to the Isle of France. Commerçon remained at the Isle of France that he might thence proceed to examine the botany of Madagascar, as did Verron for the purpose of observing the transit of Venus.

In 1769 the expedition arrived at St Malo, after a voyage of two years and four months, with the loss of only seven men out of upwards of 200.

Bougainville's account of the voyage is written with simplicity, and in a temper which inclined him to view objects on the humorous side. His courage, the good humour with which he maintained subordination, and his attention to the health and comforts of the crew, are everywhere conspicuous.

The art of making astronomical observations at sea was not so much improved as it is now, and the methods for ascertaining the longitude especially were very defective. In consequence of this, Bougainville's charts are erroneous, particularly in the longitudes. Neither did he remain long enough in any place to make particular surveys.

Bougainville's life was an active one, so that little of it could be devoted to study. On his return to France his time was passed in the company of the highest circles in Paris. He had the command of a ship under De Grasse and D'Estaing; and, in April 1781, when the French fleet was beaten, he rallied some of the beaten ships, and brought them into St Eustachio. After the peace, by which the independence of the United States of America was secured, Bougainville returned to Paris. The Academy of Sciences was at that time composed of pensioned members, and of associates who had no salary; Bougainville solicited and obtained the place of associate of the academy.

He had a project of making a voyage of discovery towards the north pole. As this did not meet with support from the French government, he sent his plan to Admiral Phipps; Phipps, however, followed a different course from that proposed by Bougainville, but he only got to the 80th degree of north latitude.

Recourse was had to Bougainville in order to repress the mutinous disposition of the sailors in the French navy before the breaking out of the Revolution; but his efforts were ineffectual. He had the rank of vice-admiral in 1791. In 1792 he escaped almost miraculously from the massacres of Paris, and went to live on his estate in Normandy. He was much attached to the government, which was then falling. He lived on his estate for some time; it was the only part of his fortune that the Revolution had left him. He was chosen a member of the Institute at its first formation, and, in consequence, returned to reside in Paris. He succeeded Borda as member of the Board of Longitude. In his old age, under the government of Bonaparte, he enjoyed the dignity of senator, and was created a count and member of the Legion of Honour.

He retained his good-humoured liveliness and his mental faculties to the last, and died in 1811, aged eighty-two. He was married, and had three sons who served in the French army. He was always eager to promote science; and he conducted himself during the Revolution in such a manner as to obtain the respect of all parties. His éloge is written by Delambre, in the *Memoirs of the Institute*. (B. B.)

BOUGAINVILLE'S Island, in the South Pacific Ocean, is high and mountainous, with extensive plains interposed, and is entirely covered with trees. It is inhabited, and is

separated from the island of Bouka on the north. Long. Bougainville 155. 20. E. Lat. 6. S.

BOUGEANT, WILLIAM HYACINTH, a famous Jesuit, born at Quimper 4th November 1690, first taught humanity at Caen and Nevers, and afterwards settled at the college of Louis the Great, where he employed himself in writing several works. The principal of these are, 1. A Collection of Physical Observations, extracted from the best authors; 2. A History of the Wars and Negotiations which preceded the treaty of Westphalia; 3. The Female Doctor, a philosophical amusement on the language of beasts; 4. The Marvellous Voyage of Prince Fanferdin in Romancia; 5. Exposition of the Christian Doctrine; and 6. Anacreon and Sappho, a dialogue in Greek verse. He died in 1743.

BOUGH, a term nearly synonymous with *Branch*. Anciently green boughs formed part of the decoration of altars and temples, especially on festive occasions. Boughs of oak were offered to Jupiter, of laurel to Apollo, of olive to Minerva, of myrtle to Venus, of ivy to Bacchus, of pine to Pan, and of cypress to Pluto.

BOUGIE. See SURGERY.

BOUGUER, PETER, an eminent French mathematician, was born in 1698. His father was king's professor of hydrography at Croisic in Lower Brittany, one of the best hydrographers of his time, and author of an excellent treatise on navigation. Young Bouguer was bred to mathematics from his infancy, and made rapid progress in that science. At an early age he was appointed to succeed his father in the chair of professor of hydrography, after having undergone a strict examination in mathematics, so as completely to satisfy his examiners. In 1727 he gained the prize given by the Academy of Sciences of Paris for his paper "On the best manner of forming and distributing the masts of ships." He got two other prizes from the academy in the course of four years: the one was bestowed on him for his dissertation "On the best method of observing the altitude of stars at sea;" the other for his paper "On the best method of observing the variation of the compass at sea." These papers are published in the *Prix de l'Académie des Sciences*. In 1729 he published a work entitled *Essai d'Optique sur la Gradation de la Lumière*, the object of which is to define the quantity of light which is lost by passing through a given extent of the atmosphere. He finds the light of the sun to be 300 times more intense than that of the moon.

He was soon after made professor of hydrography at Havre, whereby he had the advantage of being nearer Paris than before; and he was chosen associate geometer of the Academy of Sciences, an office which did not require residence in Paris. In this office he was the successor of Maupertuis. Afterwards he was promoted in the academy to the place of pensioned astronomer, and came to reside in Paris.

It was resolved in France to send an expedition to South America for the purpose of measuring a degree of the meridian near the equator. From that measurement, compared with the length of a degree of the meridian in other latitudes, the deviation from sphericity in the figure of the earth might be known. The academy made choice of four of its members to proceed on this voyage; they were Godin, Bouguer, and De la Condamine, for the geometrical operation, and the younger Jussieu for observations in natural history. Bouguer and his fellow-travellers sailed from La Rochelle in 1735, and it was ten years before he returned to France. The account of his operations during the expedition is given by him in the *Memoirs of the Academy of Sciences*, 1744, and in a separate work entitled *La Figure de la Terre déterminée par les Observations de MM. Bouguer et De la Condamine*. There is like-

wise an account of this expedition published by Don George Juan and Don Antonio de Ulloa, two scientific naval officers, who accompanied the expedition by order of the Spanish government. The length of a portion of the meridian was measured on the ground by means of a base and a set of triangles. Then, by observing the altitude of the ϵ of Orion which passed near the zenith simultaneously at the two ends of the meridian line that had been measured, that line was found to contain $3^{\circ} 7'$ of latitude. A star near the zenith was employed, to the end that the observation might not be affected by refraction; ϵ of Orion passed the meridian in the zenith near the middle of the line measured, so that the distance of that star south of the zenith of the northern extremity of the line was $1^{\circ} 25' 46''$; and its distance north of the zenith of the southern extremity of the line was $1^{\circ} 41' 13''$, the sum of these two numbers making $3^{\circ} 7'$. The altitude was taken by zenith sectors of a long radius. The ground on which these operations were performed was elevated 12,000 feet above the level of the sea, and 4200 feet above the neighbouring city of Quito, and situate in a plain extending from north to south, between the two ridges of the Cordillera. The northern extremity of the arc was on the equator. The length of the degree resulting was 56,767 toises; but this was the degree of a curve circumscribed round the earth at the height of 12,000 feet above the level of the sea; and the length of the degree at the level of the sea deduced from this, with some other corrections, is 56,753 toises. This length of the degree of the meridian at the equator was compared with the degree of the meridian measured in France, with the degree measured in Lapland, and with the degree of longitude deduced in the south of France. From this comparison it was concluded that the equatorial diameter of the earth is to the polar diameter as 179 to 178, and that the equatorial radius of the earth was about eight leagues longer than the polar. Since the time of Bouguer, degrees have been measured in different climates with more accurate instruments than he possessed; but the precise proportion of the equatorial and polar diameters of the earth is not yet finally ascertained. Bouguer makes the excess of the equatorial diameter above the polar to be $\frac{1}{179}$; Sir Isaac Newton made it $\frac{1}{180}$; Laplace, calculating from the lunar motion, $\frac{1}{181}$; Melanderhielm and Svanberg, from a degree measured anew in Lapland in 1783, compared with the degree measured in the province of Quito, $\frac{1}{183}$. Bouguer found the seconds pendulum $\frac{36}{100}$ of a line shorter at the summit of Pichincha than at the level of the sea; that is, the force of gravity was less by one 1200th part at that elevation.

He made some observations on the limit of perpetual snow, a subject which has been elucidated since his time by the researches of Humboldt, Von Buch, Wahlenberg, and others. At the equator the limit of perpetual snow is at 14,760 feet above the sea, a height equal to that of Mont Blanc. In Mexico, in the latitude of $19^{\circ} 20'$, it is at 13,800 feet, according to Humboldt. In latitude $28^{\circ} 15'$, where the Peak of Teneriffe is situate, it is supposed to be 11,700 feet: the Peak is only 11,454 feet, and has no perennial snow. On Etna, in latitude $37^{\circ} 30'$, the edge of the perennial snow is at the height of 9000 feet. On Mount Caucasus, in latitude $42^{\circ} 30'$, the limit is at 9900 feet; whilst on the Pyrenees, in latitude $42^{\circ} 45'$, it descends to 8400 above the sea; and on the Swiss Alps, in latitude 46° , to 8220 feet. In Iceland, in latitude 65° , the edge of the perennial snow is at the perpendicular height of 2892 feet from the sea. In Lapland, in latitude 67° , where the summers are warmer than in Iceland, though the winters are colder, the perennial snow does not descend so low, attaining only to 3300 French feet from the sea, as Von Buch and Wahlenberg ascertained by barometrical

observations. When the latitudes are the same, a solitary mountain will have the edge of the perennial snow higher than a mountain surrounded by others, on account of the warm winds from the neighbouring plains. A mountain in an inland situation will have the border of the perennial snow higher than a mountain in the same latitude, and situated in an island, the summers which reduce the limits of the snow being warmer in the inland situation. When the mass of perennial snow is large, glaciers are formed which descend below the limit of perennial snow. Chimborazo has 5400 feet of its height covered with perpetual snow, according to Humboldt. Bouguer thought he could perceive that the clouds do not ascend higher than 2400 feet above the summit of Chimborazo. If there were mountains whose height reached beyond the greatest height to which the clouds attain, all the part of the mountain above the region of the clouds would be free from snow, although exposed to intense cold. On Bouguer's supposition of the height to which the clouds ascend, the upper limit of snow at Chimborazo would be at the height of 22,200 feet above the sea; and the distance between the upper limit of snow and the lower limit would be there about 7800 feet.

Bouguer, whilst he was at the equator, made observations to ascertain the obliquity of the ecliptic, which he found to be $23^{\circ} 28' 28''$. He also made some experiments on the deviation of the plumb-line from the vertical, occasioned by the attraction of a neighbouring mountain, a phenomenon afterwards investigated by Dr Maskelyne on the mountain Schellien.

The number of Bouguer's papers contained in the printed Memoirs of the Academy of Sciences, is a proof of the assiduity with which he performed his duty in the academy. His *Helimeter* is described in the Memoirs of the Academy for 1748. It is an object-glass micrometer, and its essential parts consist of an astronomical dioptric telescope, with two object-glasses of the same focal length placed side by side. When this instrument is directed to the sun, each object-glass gives an image of that luminary; and the object-glasses are so placed that the limbs of the two images touch when the diameter of the sun is greatest, and when the diameter is less there is an interval between the limbs of the two images.

Some experimenters maintained that the plumb-line had a diurnal oscillation; Bouguer showed that it remains at rest. He employed for this purpose a telescope, attached to the end of a chain 187 feet long, suspended within the dome of the church of the Hospital of Invalids at Paris: the telescope was directed to a distant mark, so that any motion in this long pendulous system might be seen by the deviation of the wires of the telescope from the mark. The particulars of this experiment are to be found in the *Mém. de l'Académie des Sciences*, 1754.

In the volume for 1739 and 1749 there are papers of his on the astronomical refraction in the torrid zone, particularly in cases where the star is seen at more than 90° from the zenith, in consequence of the observer being in a high situation. In the volume for 1747, he proposed a log of a new construction for measuring a ship's way.

In the same collection there are papers of his on the length of the pendulum, on the form of the prow which suffers least resistance in passing through the water, and on a variety of other subjects. He bestowed great pains on his works, and his health at length became impaired by a sedentary life, and too constant application to scientific pursuits. He died in 1758, aged sixty. His disposition was naturally mild, and the dissensions that arose between him and his fellow-traveller De la Condamine caused him great vexation. He was impressed, from his earliest years, with a conviction of the truths of Christi-

Bouhours. anity. By economy he had acquired a moderate fortune, a part of which he bequeathed to the poor.

The following is a list of his principal works: *Traité d'Optique sur la Gradation de la Lumière*, 1729 and 1760. *Entretiens sur la Cause de l'Inclinaison des Orbites des Planètes*, 1734; another edition in 1749. *Traité de Navire, de sa construction, et de ses mouvemens*, 1746, 4to. *La Figure de la Terre déterminée, par les Observations de Mess. Bouguer et de la Condamine, envoyés par ordre du Roy au Pérou*; par M. Bouguer, 1749, 4to. *Nouveau Traité de Navigation, contenant la Théorie et la Pratique du Pilotage*, 1753. A new edition by De la Caille, 1761. *Solution des Principaux Problèmes sur la Manœuvre des Vaisseaux*, 1757. *Opérations faites pour la Verification du Degré du Méridien entre Paris et Amiens*; par Mess. Bouguer, Camus, Cassini, et Pingré, 1757.

After his return from South America he was editor of the *Journal des Savans*. Some of his papers in the *Memoirs of the Academy of Sciences* have been mentioned in this article; his *Eloge* is contained in the volume for 1758. (B. B.)

BOUHOURS, DOMINIC, a celebrated French critic, was born at Paris in 1628. He entered into the society of Jesuits at the age of sixteen, and was appointed to read lectures upon polite literature in the college of Clermont at Paris, where he had studied; but he was so incessantly attacked with headachs, that he found himself unable to execute the task assigned him. He afterwards undertook the education of two sons of the Duke of Longueville, which he conducted with great applause. The duke had such a regard for Bouhours that he died in his arms; and the "account of the pious and Christian death" of this great personage was the first work which Bouhours gave the public. He was sent to Dunkerque to the Popish refugees from England; and, in the midst of his missionary occupations, found means to compose and publish books. Among these were *Entretiens d'Ariste et d'Eugène*, a work of a critical nature on the French language. His book was printed no less than five times at Paris, twice at Grenoble, and afterwards at Lyons, at Brussels, at Amsterdam, at Leyden, and other places; and it embroiled him in quarrels with a great number of persons, particularly Menage, who, however, lived in friendship with the author before and after. The fame of this piece, and the pleasure he took in reading it, recommended Bouhours so effectually to the celebrated minister Colbert, that he intrusted him with the education of his son the Marquis of Segnelay. He afterwards wrote several other works, the chief of which are, 1. Remarks and Doubts upon the French Language, 1694; 2. Dialogues upon the art of Thinking Well in works of Genius, 1687; 3. The Life of St Ignatius, 1679; 4. The Art of Pleasing in Conversation; 5. The Life of St Francis Xavier, apostle of the Indies and of Japan, 1682. This last work was translated from the French into English by Mr Dryden, and published at London in the year 1668, with a dedication to James II.'s queen prefixed. Bouhours's works may be divided into two classes, namely, those of a religious, and those of a purely literary character; and the number of the one is nearly equal to that of the other. It was his practice indeed to publish alternately a book on literature and a work on some subject of piety; which gave occasion to a wag, in a satirical epitaph, to remark of him "qu'il servait le monde et le ciel par semestre." His *Pensées ingénieuses des Anciens et des Modernes*, though at once instructive and amusing, exposed him to censure as well as ridicule, on account of some strange misjudgments and omissions. Either from spite or misconception, he has classed Boileau with the least esteemed of the Italian satirical versifiers, thus placing him in the worst company he could possibly find; and what

is still more extraordinary, he has ingeniously omitted, in his Thoughts on the Moderns, all mention of the illustrious name of Pascal. This gave occasion to a variety of epigrams at the expense of the worthy father, particularly to the following by Madame Deshoulières:

Père Bouhours, dans vos *Pensées*,
La plupart fort embarrassées,
A moi vous n'avez point pensé.
Des célèbres auteurs que votre livre chante,
Dans une liste triomphante
Je ne vois point mon nom placé;
Mais aussi dans le même rôle
Vous avez oublié Pascal,
Qui pourtant ne pensait mal:
Un tel compagnon me console.

BOUKA, or LORD ANSON'S ISLAND, in the South Pacific Ocean, lying south of Bougainville's Island, is covered with wood from the shore to the centre, which is of considerable height. Along the beach are extensive plantations of cocoa-nut trees. Their canoes are ingeniously constructed; and they are remarkably dexterous in the use of the bow and arrow, bringing down birds on the wing with almost unerring certainty. Long. of the north cape, 153. 34. E. Lat. 5. 0. S.

BOULAINVILLIERS, HENRY DE, Lord of Saint Saire, and an eminent French writer, was descended from a very ancient and noble French family, and born at Saint Saire in 1658. He received his education among the fathers of the oratory, at the college of Juilli, where he discovered from his infancy the uncommon abilities for which he was afterwards distinguished. He applied himself principally to the study of history; and his performances in this department are numerous and considerable, but deformed by an extravagant admiration of the feudal system, which he regarded as the *chef d'œuvre* of the human mind. To this idea he incessantly recurs in all his writings, and misses no opportunity of regretting those good old times, in which the people, enslaved by petty tyrants alike ignorant and barbarous, had neither industry, nor commerce, nor property, and in which a hundred seignurs, the oppressors of the country and the enemies of the king, composed what he is pleased to consider the most perfect of all governments. He was the author of a History of the Arabians; Fourteen Letters upon the ancient Parliaments of France; a History of France to the reign of Charles VIII.; and the State of France, with historical memoirs concerning the ancient government of that monarchy, to the time of Hugh Capet, "written," says M. Montesquieu, "with a simplicity and honest freedom worthy of that ancient family from which their author was descended." M. Boulainvilliers died at Paris in 1722, and after his death was published his Life of Mahommed.

BOULANGER, NICHOLAS ANTHONY, a very singular Frenchman, was born at Paris in 1722, and died there in 1759, aged only thirty-seven. During his education he is said to have come out of the college of Beauvais almost as ignorant as he entered it; but struggling hard against his unaptness to learn, he at length overcame it. At seventeen he began to study mathematics and architecture; and in three or four years made such progress, as to be useful to the Baron of Thiers, whom he accompanied to the army in the capacity of engineer. Subsequently he had the superintendence of the highways and bridges; and he executed several public works in Champagne, Burgundy, and Lorraine. The author of his life, in the *Dictionnaire des Hommes célèbres*, writes, that in this province a terrible spirit discovered itself in him, which he himself did not discover before; and this was, it seems, the spirit of "thinking philosophically." In cutting through mountains, in directing and changing the courses of rivers, and in breaking up and turning over the strata of the earth, he

Boulanger saw a multitude of different substances, which, he thought, evinced the great antiquity of it, and a long series of revolutions which it must have undergone. From the revolutions in the globe, he passed to the changes that must have happened in the manners of men, in societies, in governments, in religion; and he formed many conjectures upon all these. To be further satisfied, he wanted to know what, in the history of ages, had been said upon these particulars; and, that he might derive information from the fountain head, he learned first Latin, then Greek, and afterwards Hebrew, Syriac, Chaldaic, and Arabic; and, by dint of unwearied perseverance, acquired such a stock of erudition, that, if he had lived, he would have been one of the most learned men in Europe. But, as we have observed, death stepped in and cut him off in the full vigour of life, while ardently pursuing his studies. His principal works are, 1. *Traité du Despotisme Oriental*, 2 vols. 12mo, 1761. 2. *L'Antiquité dévoilée*, 3 vols. 12mo, 1761; posthumous. 3. He furnished to the *Encyclopédie* the articles *Déluge*, *Corvée*, *Guèbres*, *Langue Hébraïque*, and *Economie Politique*. 4. He left behind him, in manuscript, a Dictionary, which may be regarded as a concordance of ancient and modern languages. As a man, he is said to have been of a sweet, calm, and engaging temper; which, however, it is very difficult to reconcile with the dark, impetuous, ardent spirit, which appears to have animated him as a writer. During the latter period of his life he was connected with a set of writers, illustrious in point of talent, but utterly devoid of all principle, who openly professed themselves the enemies of religion, and were heated with the idea of effecting its destruction. In the society of these men, whose opinions he participated, Boulanger contributed his share to the common enterprise, by the arguments which he drew from his studies and the hypotheses he had conceived; but several of the irreligious writings which have been ascribed to him are nevertheless not of his composition, and his memory ought therefore to be exonerated from the opprobrium which has in consequence been cast upon it. He was a speculative infidel, not a common blasphemer, and ought not to be held answerable for the abominations which weaker and worse men have published in his name.

BOULANGER, *John*, an engraver, was a native of France, and born at Amiens in 1607. His first manner of engraving appears to have been copied, in some degree, from that of Francis de Poilly; but soon after he adopted one of his own, which, though not original, he nevertheless greatly improved. He finished the faces, hands, and all the naked parts of his figures, very neatly, with dots instead of strokes, or strokes and dots; and the effect, though singular enough, is by no means displeasing. In some few instances, however, the coarse graving of his draperies and back ground presents so violent a contrast to the neater work of the flesh, that the outline of the latter is rendered hard, and the general appearance of it flat and chalky. He did not draw the naked parts of his figures correctly, or in good taste; whilst his draperies are heavy, and the folds not well marked. However, his best prints possess merit, and are deservedly held in considerable esteem.

BOULAY, CÉSAR EGASSE DU, in Latin *Bulæus*, was born at St Ellier, on the Lower Maine, in the beginning of the seventeenth century, and became professor of humanity at the college of Navarre, as well as register, rector, and historiographer of the university of Paris. He died in 1678, after having published several works. The principal of these are, a History of the University of Paris, in Latin, 6 vols. folio, 1665 and 1673; and the *The-saurus of Roman Antiquities*, in one volume folio.

BOULDER-WALL, a kind of wall built of round flints

or pebbles, laid in strong mortar, and used where the sea has a beach cast up, or where there are plenty of flints.

BOULETTE, in the manège. A horse is called *boulette* when the fetlock, or pastern joint, bends forward, and out of its natural situation, whether through violent riding, or by reason of the animal being too short jointed, in which case the least fatigue will bring it down.

BOULOGNE, an arrondissement of the department of the Pas de Calais, in France, extending over 348 square miles, comprehending six cantons and 100 communes, and containing 76,220 inhabitants. The chief city, of the same name, on the sea shore, is divided into the lower and the upper town, together having six churches, a hospital, 1600 houses, and 16,650 inhabitants. In the summer it is resorted to for sea-bathing both by English and French visitors. It is a place of some trade, but its harbour is only capable of admitting vessels at high tides. Long. 1. 30. 43. E. Lat. 50. 43. 33. N.

BOULTER, DR HUGH, was born in or near London, of reputable and wealthy parents. He was educated at Merchant-Tailor's School before the Revolution, and was from thence admitted a commoner of Christ-church in Oxford. Some time afterwards he was chosen a demy of Magdalen College, at the same election with Mr Addison and Dr Wilcox. From the merit and learning of the persons elected, this was commonly called by Dr Hough, president of the college, the "golden election." He afterwards became fellow of the same college; in which station he continued till the year 1700, when he was invited to London by Sir Charles Hodges, principal secretary of state, who made him his chaplain, and recommended him to Dr Tennison, archbishop of Canterbury; but for his first preferments he was indebted to the Earl of Sunderland, by whose interest and influence he was promoted to the parsonage of St Olave in Southwark, and the archdeaconry of Surrey. Here he continued discharging very faithfully and diligently every part of his pastoral office, till he was recommended to attend George I. as his chaplain when he went to Hanover in 1719. He had the honour to teach Prince Frederick the English language; and by his conduct he so won the king's favour, that he promoted him to the deanery of Christ-church and the bishopric of Bristol in the same year. As he was visiting his diocese five years afterwards, he received a letter from the secretary of state, acquainting him that his majesty had nominated him to the archbishopric of Armagh and primacy of Ireland. This honour he would gladly have declined, and desired the secretary to use his good offices with his majesty to excuse him from accepting it. At this juncture Ireland happened to be in a great flame, occasioned by Wood's project; and the ministry thought that the bishop would greatly contribute to quench it by his judgment, moderation, and address. The king therefore laid his absolute commands upon him, and he submitted, but with some reluctance. As soon as he had taken possession of the primacy, he began to consider the country in which his lot was cast for life as his own, and to promote its true interest with the greatest zeal and assiduity. Accordingly, he exerted himself in performing the noblest acts of beneficence and public spirit. In seasons of the greatest scarcity he was more than once instrumental in preventing a famine which threatened that nation. On one of these occasions he distributed vast quantities of corn throughout the kingdom, for which the House of Commons passed a vote of public thanks; and at another time two thousand five hundred persons were fed at the poor-house in Dublin, every morning, and as many every evening, for a considerable time together, mostly at the primate's expense. When schemes were proposed for the

Boulton.

advantage of the country, he encouraged and promoted them not only with his counsel, but his purse. He had great compassion for the poor clergy of his diocese, who were disabled from giving their children a proper education; and he maintained several of these children in the university. He erected four houses at Drogheda for the reception of clergymen's widows, and purchased an estate for the endowment of them. His charities for augmenting small livings and buying glebes amounted to upwards of L.30,000, besides what he devised by will for the like purposes in England. In short, the instances he gave of his generosity and benevolence of heart, his virtue, piety, and wisdom, are almost innumerable, and the history of his life is his noblest panegyric. This excellent prelate died at London, on the 2d June 1742, and was interred in Westminster-abbey, where a beautiful monument of finely-polished marble was erected to his memory.

BOULTINE, a term which workmen use for a moulding, the convexity of which is just one-fourth of a circle; being the member just below the plinth in the Tuscan and Doric capitals.

BOULTON, MATTHEW, a manufacturer and practical engineer of great celebrity, son of Matthew Boulton, by his wife Christian, daughter of Mr Peers of Chester, was born at Birmingham on the 14th of September 1728, and died in August 1809.

He was educated at a neighbouring grammar-school, kept by Mr Ansted of Deritend, and was called early into active life upon the death of his father in 1745. The various processes by which the powers of the human mind have given facility to the artist in rendering the different forms of matter obedient to his command, afforded ample scope for the exercise of his inventive faculties, in improving the manufactures of his native place. His first attempt was a new mode of inlaying steel; and he succeeded in obtaining a considerable demand for the products of his manufactory, which were principally exported to the Continent, and not uncommonly re-imported for domestic use, as of foreign manufacture.

In 1762, his fortune being already considerable, he purchased a tract of barren heath in the neighbourhood of Birmingham, with a single house on it, and there founded, at the expense of L.9000, the manufactory which has been so flourishing, and so well known under the name of Soho. His workmen were at first principally employed in the imitation of or moulu, and in copying oil paintings with great accuracy, by means of a mechanical process which was invented by a Mr Egginton, who afterwards distinguished himself by various works in stained glass. Mr Boulton finding the force of horses inadequate to the various purposes of his machinery, erected in 1767 a steam-engine, upon the original construction of Savery, which, notwithstanding the inconvenience of a great loss of steam from condensation, by its immediate contact with the water raised, has still some advantages from the simplicity of the apparatus which it requires, and has even lately been found to succeed well upon a small scale. But Mr Boulton's objects required a still more powerful machine, and he had the discernment to perceive that they might be very completely attained by the adoption of the various improvements lately made in the steam-engine by Mr Watt of Glasgow, who had obtained a patent for them in 1769, the privileges of which were extended in 1775, by an act of Parliament, to a term of 25 years. Mr Boulton induced this ingenious and scientific inventor to remove to Birmingham. They commenced a partnership in business, and established a manufactory of steam-engines, in which accurate execution kept pace so well with judicious design, that its productions continued

to be equally in request with the public after the expiration of the term of that legal privilege which at first gave the proprietors the exclusive right of supplying them, and which had been confirmed in 1792 by a decision of the Court of King's Bench against some encroachments on the right of the patentee. It was principally for the purpose of carrying on this manufactory with greater convenience, that the proprietors established an iron-foundry of their own at Smethwick, in the neighbourhood of Soho.

In 1785 Mr Boulton was made a fellow of the Royal Society, about the same time with Withering, and several others of his scientific neighbours. In 1788 he turned his attention to the subject of coining, and erected machinery for the purpose, so extensive and so complete, that the operation was performed with equal economy and precision, and the coins could not be imitated by any single artist for their nominal value; each of the stamps coining, with the attendance of a little boy only, about eighty pieces in a minute. The preparatory operation of laminating and cutting out the metal is performed in an adjoining room; and all personal communication between the workmen employed is rendered unnecessary, by the mechanical conveyance of the work from one part of the machinery to another. A coinage of silver was executed at this mint for the Sierra Leone Company, and another of copper for the East Indies, besides the pence and half-pence at present in circulation throughout England, and a large quantity of money of all kinds for Russia. In acknowledgment of Mr Boulton's services, and in return for some specimens of his different manufactures, the Emperor Paul made him a present of a valuable collection of medals and of minerals.

Mr Boulton obtained, in 1797, a patent for a mode of raising water by impulse, the specification of which is published in the ninth volume of the *Repertory of Arts*, p. 145. It had been demonstrated by Daniel Bernoulli, in the beginning of the last century, that water flowing through a pipe, and arriving at a part in which the pipe is suddenly contracted, would have its velocity at first very greatly increased; but no practical application of the principle appears to have been attempted, until an apparatus was set up in 1792 by Mr Whitehurst, for Mr Egerton of Oulton, in Cheshire, consisting of an air-vessel, communicating with a water-pipe by a valve, which was forced open by the pressure or rather impulse of the water, when its passage through the pipe was suddenly stopped by turning the cock in the ordinary course of domestic economy; and although the pipe through which the water was forced up was of moderate height, the air-vessel, which was at first made of lead, was soon burst by the "momentous force," as Mr Whitehurst very properly terms it. The apparatus had excited much attention in France, under the name of Montgolfier's hydraulic ram; and Mr Boulton added to it a number of ingenious modifications, some of which, however, are more calculated to display the vivid imagination of a projector, than the sound judgment of a practical engineer, which had in general so strongly characterized all his productions.

He died, after a long illness, in possession of considerable affluence and of universal esteem, leaving a son and a daughter to profit by the wealth and respectability which he had acquired. He was buried on the 24th of August, at Handsworth, near Soho, attended by a procession of 600 workmen, and by a numerous train of his friends and acquaintance. (*Monthly Magazine*, October 1809, p. 368.) (L. L.)

BOUNTY, in *Commerce*, a premium paid by government to the exporters of certain commodities. See *POLITICAL ECONOMY*.

BOURBON, an island in the Indian Sea, about 400 miles to the east of Madagascar. It was discovered by the Portuguese in 1545, as appears by a date inscribed by them upon a pillar when they first landed. They gave it the name of Mascarenhas, but do not appear to have formed any establishment; so that when the French settled in Madagascar, this island was totally desolate. In 1642, De Pronis, agent for the French East India Company, took possession of the island, but used it merely as a place of banishment for offenders. The exiles, however, gave so favourable a report, that, in 1649, De Harcourt, then governor of Madagascar, formed an extensive settlement, to which, from the royal family of France, he gave the name of Bourbon. The colonists, however, finding their situation uncomfortable, and receiving no support from Madagascar, embraced the offer of an English captain, and in the year 1658 embarked for Madras. When the last great blow was given to the French at Madagascar by the natives, who surprised and cut them off in one night, there escaped as many men as, with their wives, who were natives, filled two canoes; and these being driven by the wind on the isle of Bourbon, formed a fresh colony, who, for want of an opportunity to remove, were constrained to remain in and to cultivate it. It was not long before a further supply of inhabitants arrived. A pirate who had been committing depredations in the Indian seas, returning to Europe, ran ashore and had his vessel dashed to pieces on the rocks, so that the crew were forced to join the former inhabitants; and as they had on board their vessel a great many Indian women whom they had made prisoners, they lived with them, and in process of time had a numerous posterity. As East India ships touched frequently here when too late to double the Cape, many of the sailors deserted and became planters in the isle of Bourbon. When the place grew more populous, the people naturally became more civilized, and desirous of living in a more commodious manner; which induced them to build small vessels, and make trips to Madagascar in order to purchase slaves, whom they employed in their plantations to cultivate aloes, tobacco, and other products, with which they carried on a small trade when ships of any nation anchored in their roads for refreshments. In this situation the French East India Company put in their claim; and assuming the property of the island, sent thither five or six families and a governor. At first the inhabitants expected to reap some benefit from their new masters; but finding very little, and considering the governor as tyrannical, they revolted at the instigation of a priest, and seized and put him into a dungeon, where he died. Some of the ringleaders were punished, a kind of fort was erected, and a few guns placed on it; but in other respects, within the last forty years, the island was in no state of defence. The number of inhabitants in the year 1717 was computed at 2000, viz. 900 free and 1100 slaves. When the present French India Company became, by their charter, possessed of the island of Bourbon, they began very diligently to improve it; raising new forts and batteries, so as to render it in a manner inaccessible, and importing the coffee-tree from Arabia, which has succeeded so well, that it has become an extensive object of culture, and is considered as only second to that of Yemen. The clove-tree was also introduced with success. In 1811 Bourbon was captured by a British force, but restored at the general peace.

The physical structure of this island presents many striking features. It does not, like the Isle of France, consist of a level plain, from which conical hills arise in detached masses. The whole island is as it were one mountain, having its most elevated points in the centre, and thence sloping gradually down to the sea. This great

mass, however, is split into two portions, of which the loftiest, situate in the northern part, is called the *Gros Morne*, and its summit the *Piton des Neiges* or Snowy Peak. There is here no present action of volcanic fire; but the frequent occurrence of deep valleys or basins, rapid rivers bordered by perpendicular walls of rock, hillocks precipitated into these valleys and torrents, basaltic prisms often disposed in regular colonnades, strata thrown into the most irregular positions,—all these, in M. Bory de St Vincent's opinion, indicate terrible physical revolutions in former times. The northern mountain is entirely volcanic, and the phenomena present themselves in an extraordinary state of frequency and activity. This writer not only conceives both these mountains to have been originally volcanic, but the whole island to have been thrown up by the action of subterranean fire. They appear to him also to have formerly composed only one, having an intermediate summit higher than that of either now is. The volcanic agitations, however, having hollowed the internal part of this great mass, the exterior crust fell in, and reduced the island to the shattered state which it now exhibits. To a great extent indeed it is divided into two portions by an immense hollow, bordered with perpendicular walls of rock, which, after running parallel for seven or eight miles, form an arch and unite. At the foot of the volcano is found an immense track of what the inhabitants call *Brulé*, or burnt country, supposed to have been formed by the lava spreading into a species of fiery lake, and then consolidating into the present surface. It is destitute of all vegetation whatever; and its colour is of the gloomiest black, the surface being broken by holes, crevices, and innumerable asperities of every description. These, joined to its hard and brittle consistence, render it impossible to tread on it without the severest injury to the feet. Those of our traveller's attendant negroes were severely lacerated; and his own, though defended by strong shoes, were wounded in several places.

The streams of Bourbon are mere mountain torrents, which descend from steep to steep, and throw themselves into the sea. In their fall they dig deep ravines, bordered by lofty and almost perpendicular walls. The largest river, however, that of St Denis, has only a course of seven or eight miles. These deep and foaming torrents, the rude surface of the ground, and the perpendicular rents by which it is everywhere broken, render travelling through Bourbon a most arduous undertaking. M. Bory de St Vincent was assured that his plan of reaching the two principal peaks was altogether impracticable; but his enterprise and love of science enabled him to surmount all the intervening difficulties.

In the ascent to the summit of the volcanic mountain, the obstacles encountered were truly formidable. Sometimes the sides of nearly perpendicular rocks were to be climbed; at other times a road was to be made by cutting down the bushes and filling up the crevices; whilst a mist, which rises every day from the sea, rendered it impossible to distinguish his companions at the smallest distance. At length they reached the summit of the *Mamelon central*. The crater here, to which the name of Dolomieu was given, consists of a cavity forty fathoms in diameter, and about eighty feet deep, the bottom filled with confused piles of greyish coloured lava. The sides showed none of that soft lava which forms a species of varnish over the interior of other craters; they consisted of irregular fragments of hard and compact substances. Our author here notices the error of those who expect, when they reach the summit of a crater, to look down into an unfathomable abyss. The fact is, that from whatever depth the liquified substances may have ascended, as soon as the conflagration ceases, they harden and fill up the

Bourbon. opening, so that only a very small void remains. Being led, however, by a sulphureous smell, to the left side of the present crater, they discovered a deep hollow like a tunnel, the walls of which were composed of burning lava; while beneath, two columns of fiery matter, rising to the height of 120 feet, threw up a bloody light, which shone brightly, even amid the blaze of a tropical noon. This spectacle, accompanied with a sound similar to that of a mighty cascade, filled their minds with terror and admiration.

Our traveller, in ascending, had supposed the *Mamelon central* to be the highest peak of the volcanic mountain; but he now discovered, at the distance of about 200 fathoms, a still more elevated point, which, after himself, he named *Bory*. It is a vast elliptic basin, the largest diameter of which is 120, and the smallest 100 fathoms. The sides rise perpendicularly like walls, and are 200 feet high at their greatest elevation. There were some broken parts, however, by which the travellers could descend into the abyss. They found it tolerably level; but the volcanic ashes with which it was bestrewn hid the scoriæ and other substances which filled it. In the centre was a crevice, the depth of which they could not discover. This crater was entirely silent.

The travellers spent the night on the crater *Dolomicu*; but the tremendous sounds, the blaze of light, and the singularity of their situation, scarcely allowed them to close their eyes. At about 1200 feet beneath, they perceived a stream of lava issuing from the mountain, the outlet, probably, of those liquified substances which they saw fermenting at the bottom of the crater.

The crater is said to have been formed during a violent eruption of the volcano in 1791. In the beginning of June a burning vapour appeared rising from the summit, then the side of the mountain opened, and a vast torrent of lava rushed into the sea. On the 17th of July a subterranean noise, like the discharge of cannon, was heard throughout the island; after which there rose from the top of the mountain an enormous column of smoke, of a deep black, with white spots interspersed. The inhabitants, who had never before witnessed such a phenomenon, were struck with consternation. Soon, however, the column fell down, and formed a species of arch over the volcano. The falling in of the interior, undermined by the previous discharge, is supposed to have been the cause of the tremendous sound, and of the ultimate opening of the crater.

This is, perhaps, the most active volcano in nature. Since the Christian era, Etna has made only twenty-seven eruptions, and Vesuvius twenty-four. But a resident at Bourbon assured our author, that, from 1785 to 1802, the mountain had vomited flames at least twice every year, and eight of the streams had entered the sea. The lava, however, scarcely ever issues from the summit of a crater, but generally from openings far down the mountain, and sometimes almost on a level with the sea. It is remarkable, also, that earthquakes, which so generally desolate volcanic countries, are here unknown, or, at least, so slight, as to occasion no serious inconvenience. The constant escape of the subterraneous fire through the channel of the volcano may probably be the chief cause which prevents it from shaking the surrounding regions. Another usual accompaniment, that of warm springs, is also wanting; and none of the waters are impregnated with any species of gas. No petroleum has been found, nor any metal, except iron.

Our traveller next made an excursion to the *Piton des Neiges*, which forms the summit of the *Gros Morne*, the highest mountain in the island. This undertaking proved still more arduous. The season was favourable; yet, when they had mounted about half-way, a prodigious rain

came on; and the road lay through wet and swampy grounds, which were soon entirely covered with water. The mists became so thick, that nothing could be distinguished. The negroes, accustomed to a milder air, were benumbed; and, refusing to proceed, would have perished with cold, had not the Frenchmen driven them forcibly on, till they came to a spot where they found shelter and refreshment. They spent here two nights, and on the third day were able to reach their destination. The view from the summit appeared to our traveller to equal the most majestic scenes of the Alps and the Pyrenees. In the island beneath, every object was visible as on a map; while, on every side, the immeasurable extent of ocean mingling with the skies, made them feel as if insulated on this spot from the rest of the universe. The thermometer was so low as 8°. Here considerable masses of rock were observed, undermined to such a degree that a very slight effort was sufficient to throw them down the precipices, where, displacing others, they rolled to a great depth, and caused prodigious havoc. Every part of the mountain, indeed, appears furrowed and shattered by the violent action of the rains, which have already sensibly diminished its magnitude, and are likely to do so more and more.

M. Bory does not appear to have instituted any investigation into the height of these mountains. Professor Jameson, in his *Geognosy*, estimates that of the *Gros Morne* at 9600, and that of the volcano at 7680 feet above the level of the sea. The French traveller gives a copious, but not very precise account of its geological features. The lower part of the *Gros Morne* is composed of basalt, a substance which abounds in every part of the island, and which, from the manner in which it is connected with and surrounded by lava, is conceived by our author to have been universally crystallized from a state of fusion. He notices, also, the frequent occurrence of what he calls *trappean lava*; though this, as well as much of the basalt, would probably, by the disciple of Werner, be referred to some of the newer formations of trap. On some of the precipices at the summit of the *Gros Morne*, there appeared an immense depth of horizontal strata, which might have rendered an igneous origin improbable, had it not been so clearly proved by other phenomena. Large blocks of granite are found in the rivers which flow at the foot of the *Gros Morne*.

It is now time to take a view of the political and commercial aspect of Bourbon. By the revolutionists it was called Reunion; but this name, which was never fully established, may be now supposed to have again given place to its ancient appellation. The island is divided into eleven parishes, St Denis, containing the capital of that name, St Marie, St Susanne, St André, St Benoit, St Rose, St Joseph, St Pierre de la Rivière d'Abord, St Louis du Gaul, St Leu, and St Paul. St Denis can scarcely be called a city; the streets resemble roads in the country, being covered with grass and sand, under which are often concealed sharp pointed stones, which inflict severe wounds on the feet. The houses are built of wood, and are agreeable; they are constructed entirely with a view to coolness. The furniture is slender, and many of the rooms are not even carpeted; a deficiency not arising from absolute poverty, but from the difficulty, in this remote situation, of procuring the artificial conveniences of life. The houses in the country are of a peculiar construction, very long, very narrow, and tapering to a point.

The island is distinguished into the windward and leeward quarters; of which the former, descending by a gentle slope, and refreshed by continual breezes, is fertile and smiling; while the latter is comparatively rude, dry, and barren. The torrents, continually washing away the

soil, are supposed to augment the sterility. Only a narrow slope, about a league and a half inward from the sea, is under regular cultivation. The interior consists of immense forests, inhabited by a species of fugitive mulattoes, who live almost in a state of nature. The population in 1763 was estimated by Bory de St Vincent at 4000 whites and 15,000 slaves. If these numbers are at all accurate, the increase must have been very great. The enumeration of 1827 gave 18,747 whites, 6387 free people of colour, 41,340 males, and 22,107 female slaves; in all 88,581.

The staple production of this island is coffee. The first plants were early brought from Arabia, and soon flourished to such a degree, that the coffee of Bourbon was only second to that produced in the parent district. During the revolution, the want of a regular market, by diminishing the encouragement to careful cultivation, sensibly lowered the quality. It is still, however, produced in large quantity. Next to it ranks the article of cloves. The clove-tree is of very easy cultivation; the chief disadvantage is the precariousness of the produce. It has been known in one year to yield only 1000 lbs., and in the next 500,000 lbs. Cotton, likewise, has been long a staple of the island; but a violent hurricane in 1801, and a disease which afterwards made its appearance among the plants, discouraged a number of the planters, who accordingly began to employ their lands in the culture of coffee. During the last ten or twelve years the culture of coffee, cotton, and cloves, has diminished, partly from local causes, and partly from the low price which they bear in Europe. On the other hand, that of sugar has very remarkably increased. In 1820 the produce was only from four to five millions of kilogrammes; in 1828 it had risen to thirteen, and in 1829 to twenty-nine millions. In 1827 the quantity of land employed in the production of sugar was stated at 8241 hectares, coffee 8909, spices 4993, grains 28,840. Bourbon labours under the serious disadvantage of not possessing a single harbour, nor any roadstead in which vessels can ride with safety. The trade, therefore, can be conducted only through the medium of Mauritius, and is entirely in the hands of the merchants of that island. (E.)

BOURBON, *Nicholas*, a Latin poet of the sixteenth century, was a native of Vandœuvre, near Bar-sur-Aube, and the son of a blacksmith. He was so learned in the belles-lettres, and particularly in Greek, that Margaret de Valois appointed him preceptor to her daughter Jane d'Albret of Navarre, the mother of King Henry IV. After a residence of several years at court he retired to Candé, where he had a benefice, and died about the year 1550. He wrote eight books of *Nugæ*; a poem on the forge, which he has entitled *Ferraria*; *Pædologia, sive de Puerorum moribus Libellus*; *Tabellæ Elementariæ*; and a Dialogue on the death of Francis of Valois and the accession of Henry. Erasmus praises his *Nugæ*.

BOURBON, *Nicholas*, a celebrated Greek and Latin poet, was nephew to the preceding. He taught rhetoric in several colleges of Paris; and the Cardinal de Perron caused him to be nominated professor of eloquence in the Royal College. He was also canon of Langres, and one of the forty of the French academy. At length he retired to the fathers of the oratory, where he died in 1644, aged seventy. He is esteemed as one of the greatest Latin poets France has produced. His poems were printed at Paris in 1630.

BOURBON-VEKDÉE, an arrondissement in the department of Vendée, in France, extending over 630 square miles, and comprehending eight cantons and seventy-three communes, with 65,171 inhabitants. The chief place, now of the same name, formerly La Roche-sur-Yon, and

then Ville Napoleon, has been built since the civil war which devastated the department to which it belongs.

BOURCHIER, JOHN, Lord Bernars, grandson and heir of a lord of the same name, who was descended from Thomas of Woodstock, Duke of Gloucester, and had been knight of the Garter and constable of Windsor-castle. Under Edward IV. this Lord John was created a knight of the Bath on the marriage of the Duke of York, second son of Edward IV., and was first known by quelling an insurrection in Cornwall and Devonshire, raised by Michael Joseph, a blacksmith, in 1495, which service recommended him to the favour of Henry VII. He was a captain of the pioneers at the siege of Therouanne, under Henry VIII. by whom he was made chancellor of the exchequer for life, and lieutenant of Calais and the Marches; appointed to conduct the Lady Mary, the king's sister, into France on the marriage with Louis XII.; and had the extraordinary fortune of continuing in favour with Henry VIII. for the space of eighteen years. He died at Calais in 1532, aged sixty-three. By King Henry's command he translated Froissart's *Chronicle*, which was printed in 1532 by Richard Pinson, the scholar of Caxton, and the fifth on the list of English printers. His other works were a whimsical medley of translations from French, Spanish, and Italian novels, which seem to have been in vogue then, as they were afterwards in the reign of Charles II. These were, the *Life of Sir Arthur*, an Armoric Knight; the *Famous Exploits of Sir Hugh Bourdeaux*; *Marcus Aurelius*; and the *Castle of Love*. He composed also a book on the duties of the inhabitants of Calais; and a comedy entitled *Ite in Vineam*, which is mentioned in none of our catalogues of English plays. Anthony Wood says it was usually acted at Calais after vespers.

BOURDALOUE, LOUIS, a celebrated preacher among the Jesuits, and one of the greatest orators that France has ever produced, was born at Bourges on the 20th of August 1632. At the age of sixteen he entered the Society of Jesus, of which he was destined to become one of the greatest ornaments, and there completed his studies. His able masters, who early distinguished his talents, successively confided to him the chairs of humanity, of rhetoric, of philosophy, and of moral theology; and it was only after passing through these different probationary employments that he arrived at the eminent post which was designed for him, and was deemed qualified for mounting the pulpit.

In order to form an idea of the difficulties which he had to surmount, and of the talents which he displayed, it is only necessary, on the one hand, to call to mind the ridiculous manner and inflated style of the preachers of that period; and, on the other, to figure the young Jesuit at issue with the bad taste as well as the bad habits of the time; combating at once the passions, the vices, the weaknesses, and the errors of humanity, and overcoming his enemies, sometimes with the arms of faith, and sometimes with those of reason.

At first he preached for some time in the province, but his superiors afterwards called him to Paris. This took place in 1669, at the most brilliant epoch of the age of Louis XIV., when nothing was talked of but the victories of Turenne, the festivities of Versailles, the master-pieces of Corneille and Racine, the encouragement afforded to the arts, and the general impulse given to the human mind. Bourdaloue suddenly appeared in the midst of these fascinations, and, far from diminishing their effects, the severity of his ministry, and the gravity of his eloquence, served rather to enhance their splendour. His first sermons met with prodigious success, and all voices were raised in loud applause of the preacher. Madame de Sévigné, sharing the universal enthusiasm, wrote to her daughter that "she had never heard anything more beautiful, more noble,

Bourchier
||
Bourdaloue.

Bourdaloue.

more astonishing, than the sermons of Father Bourdaloue." Louis XIV. also wished to hear him, and the new preacher was in consequence sent to court, where he preached the Advent in 1670, and the Lent in 1672; and he was afterwards called for the Lents of 1674, 1675, 1680, and 1682, and for the Advents of 1684, 1689, and 1693. This was a thing unheard of before, the same preacher being rarely called three times to court. Bourdaloue, however, appeared there ten times, and was always received with the same ardour. Louis XIV. said that "he loved better to hear the repetitions of Bourdaloue than the novelties of any one else." After the revocation of the edict of Nantes, he was sent to Languedoc to preach to the Protestants, and confirm the newly-converted in the Catholic faith; and in this delicate mission he managed to reconcile the interests of his ministry with the sacred rights of humanity. He preached at Montpellier in 1686, with prodigious success; Catholics and Protestants being all equally eager to recognise in this eloquent missionary the apostle of truth and of virtue.

In the last years of his life Bourdaloue abandoned the pulpit, and devoted himself to charitable assemblies, hospitals, and prisons, where his pathetic discourses and insinuating manners never failed of their effect. He had the art of adapting his style and his reasonings to the condition and the understanding of those to whom he addressed either counsel or consolation. Simple with the simple, erudite with the learned, and a dialectician with sophists and disputants, he came off with honour in all the contests in which zeal for religion, the duties of his station, and love of mankind, led him to engage. Equally relished by the great and by the commonalty, by men of piety and by people of the world, he exercised till his death a sort of empire over all minds; and this ascendancy he owed as much to the gentleness of his manners as to the force of his reasonings. "His conduct," says one of his contemporaries, "is the best answer that can be made to the *Lettres Provinciales*." No consideration was ever capable of altering his frankness or corrupting his probity.

Boileau, who detested the Jesuits, loved and often visited Bourdaloue. He may with justice be regarded as the reformer of the pulpit and the founder of Christian eloquence among the French. That which distinguishes him from other preachers is the force of his reasoning, and the solidity of his proofs. Never did Christian orator infuse into his discourses more majesty, dignity, energy, and grandeur. Like Corneille, he has been charged with overlabouring his diction, and accumulating idea upon idea with a needless superfluity of illustration,—of speaking more to the understandings than to the hearts of his auditors, and sometimes enervating his eloquence with too frequent a use of divisions and subdivisions. But even in subscribing to these criticisms, which are to a certain extent well founded, it is impossible not to admire the inexhaustible fecundity of his plans,—the happy talent, *velut imperatoria virtus*, which he possessed, of disposing his reasonings in the order best calculated to command victory,—the exact, constrictive logic with which he excludes sophisms, contradictions, and paradoxes,—the art with which he lays the foundations of our duty in our interest,—and, finally, the inestimable secret of converting the details of manners and habits into so many proofs of his subject. Parallels have often been drawn between Bourdaloue and Massillon; but the talents of these great pulpit orators lay in different directions, and they may therefore be more fitly contrasted than compared. If Massillon is now read with a more lively interest, he owes this advantage to the charms of his style rather than to the force of his reasonings. Among the cri-

tics of the present day, the preference is unhesitatingly given to the rival of Racine, to the painter of the heart, to the author of the discourse on the small number of the elect; but if we consult the contemporaries of Massillon himself, we shall find that they assign him only the second rank. According to them, Bourdaloue preached to the men of a vigorous and masculine age; Massillon to those of a period remarkable for its effeminacy. Bourdaloue raised himself to the level of the great truths of religion; Massillon conformed himself to the weakness of the men with whom he lived. The bishop of Clermont will always be read; but if the simple Jesuit could raise his commanding voice from the tomb, and again roll forth a majestic stream of divine truth, the courtly accents of his rival would no longer be heard, and the charms of his diction would be forgotten. The first part of his celebrated *Passion*, in which he proves that the death of the Son of God is the triumph of his power, has generally been considered as the great masterpiece of Christian eloquence. Bossuet has said nothing stronger or more elevated. The second part, however, is inferior to the first, though, considered by itself, alike beautiful and convincing.

The discourses of Bourdaloue have been described by a celebrated French critic as embodying in them a complete course of theology. This is perhaps going a little too far; but still their general merit is very great, and for nothing are they more distinguished than their comprehensiveness. As to the diction of this great preacher, it is always natural, clear, and correct; sometimes deficient in animation, but without vacuity or languor, and generally relieved by outbursts of much force and originality. With regard to his proofs, again, nothing can be more irresistible, when he confines himself to the exposition of the great doctrines and precepts of Christianity. He generally promises to demonstrate, but he does so because he is conscious of his strength; and he never fails to keep his word. "Au total," says the critic above referred to, "je croirais que Massillon vaut mieux pour les gens du monde, et Bourdaloue pour les prédicateurs; l'un attirera le monde à la religion, par tout ce qu'elle a de douceur et de charmes; l'autre éclairera et affermira le Chrétien dans sa foi, par tout ce qu'elle a de plus haut en conception et de plus fort en appui." Two editions of Bourdaloue's works were published at Paris in 1707 and the years immediately following, by Père Bretonneau, a Jesuit; one in 14 volumes 8vo, and the other, from which the editions of Rouen, Toulouse, and Amsterdam, were afterwards printed, in 15 volumes 12mo. The works are distributed as follows, viz. 1. *Deux Avents, prêché devant le Roi*, 1 vol.; 2. *Carême*, 3 vols. 8vo, or 4 vols. 12mo; 3. *Mystères*, 2 vols.; 4. *Fêtes des Saints, Vêtures, Professiones, Oraisons Funèbres*, 2 vols.; 5. *Dominicales*, 3 vols.; 6. *Exhortations et Instructions Chrétiennes*, 2 vols.; 7. *Rétraite Spirituelle*, 1 vol.; 8. *Pensées*, in 2 and in 3 vols. In 1812, the Abbé Sicard published at Paris, in 8vo and in 12mo, *Sermons Inédits de Bourdaloue*; and soon after appeared the Versailles edition of the *Œuvres de Bourdaloue* in 16 volumes 8vo. (*Vie de P. Bourdaloue*, par Madame de Pringy; *Esprit de Bourdaloue*, par l'Abbé de la Porte; and *Biographie Universelle*.) (A.)

BOURDEAUX, an arrondissement in the department of the Gironde, in France, extending over 1668 square miles, and comprehending eighteen cantons and 153 communes, with a population of 222,268 persons. The capital is the city which gives its name to the arrondissement. It is the see of an archbishop, and situated in a broad plain, in a circular form, on the left bank of the river Garonne, about 45 miles from its mouth, over which is a bridge 3600 feet in length. It is a well-built city, and, since the return of peace, its trade has flourished, while a great im-

Bordeaux provement has taken place both in its extent and its beauty. Some of the streets are peculiarly striking, especially in the quarter called Chapeau Rouge, as well as several of the public buildings, particularly the palace, the grand theatre, the exchange, and the cathedral. As a place of commerce it is superior to any other in France, and vessels sail to and arrive from every part of the world. The chief articles exported are wine, brandy, and liqueurs. It is also a manufacturing city, and in it are large refineries of sugar, snuff and tobacco mills, potteries, glass-houses, and other branches of industry. As a sea-port, Bourdeaux possesses between 300 and 400 ships, employed chiefly in the trade with the colonies. The inhabitants are said to have increased so as now to amount to 100,000, besides the soldiery. Long. O. 40. 4. W. Lat. 44. 50. 14. N.

BOURDELOT, JOHN, a learned French critic, who lived at the close of the sixteenth and beginning of the seventeenth centuries. He distinguished himself by annotations on Lucian, Petronius, and Heliodorus; a Universal History; Commentaries on Juvenal; a Treatise on the Etymology of French words; and several other works which were never published. There was also an Abbé Bourdelot, nephew of John, who changed his name from Peter Michon to oblige his uncle. He was a celebrated physician in Paris, and gained great reputation by a Treatise on the Viper, and other works. He died in 1685.

BOURDON, SEBASTIAN, a painter, born at Montpellier in 1616. He studied seven years at Rome, and acquired so great a reputation, that, on his return to France, he was appointed rector of the academy of painting in Paris, being the first who held that office. He succeeded better in landscapes than in history. His pieces are seldom finished, and those which received his last touches are not always the finest. The most esteemed of all his performances is the martyrdom of St Peter, drawn for the church of Notre Dame, and kept as one of the choicest rarities of that cathedral. Bourdon was a Calvinist, and much valued and respected, even in a Catholic country, because his life and manners were unexceptionable. He died in 1673, aged fifty-four.

BOURG, an arrondissement of the department of Ain, in France, 672 square miles in extent, comprehending ten cantons and 119 communes, with 111,927 inhabitants. The capital, a city of the same name, on the river Reyssouse, has several cotton manufactories and tanneries, and 7417 inhabitants. Long. 5. 8. E. Lat. 46. 12. N.

BOURGANEUF, an arrondissement of the department of the Creuse, in France, comprehending four cantons and forty-nine communes, with 33,249 inhabitants. Its extent is 368 square miles. The chief place is a market-town of the same name, containing 2150 inhabitants.

BOURGES, an arrondissement of the department of the Cher, in France, extending over 942 square miles, containing ten cantons and 121 communes, with 89,594 inhabitants. The chief place, a city of the same name, is situated at the confluence of the rivers Aron and Evre. It still retains the old Roman walls, and eighty lofty towers. It is also the see of an archbishop, and, besides the cathedral, has sixteen churches, and several hospitals and other charitable foundations. The inhabitants are 18,200. Long. 17. 11. E. Lat. 47. 4. N.

BOURGET, DOM JOHN, an ingenious French antiquary, was born at the village of Beaumains, near Falaise, in 1724. He was educated at the grammar school at Caen, whence he was removed to the university of that place, and there pursued his studies with great diligence and success till 1745, when he became a Benedictine monk of the abbey of St Martin de Seëz. Some time after this he was appointed prior claustral of this abbey, and continued six years in that office. He was then nominated prior of

Tiron en Perche; and being translated to the abbey of Bourgoing. St Stephen at Caen, in the capacity of sub-prior, he managed the temporalities of that religious house during two years, as he did their spiritualities for one year longer; after which he resigned his office. His superiors, sensible of his merit and learning, removed him to the abbey of Bec, where he resided till 1764. He was elected an honorary member of the Society of Antiquaries of London in 1765; and the same year returned to the abbey of St Stephen at Caen, where he continued till the time of his death. These honourable offices, to which he was promoted on account of his great abilities, enabled him not only to pursue his favourite study of the history and antiquities of the principal Benedictine abbeys in Normandy, but likewise gave him access to all their charters, deeds, register-books, and other documents. These he examined with great care, and left behind him, in manuscript, large and accurate accounts of the abbeys of St Peter de Jumièges, St Stephen, and the Holy Trinity at Caen, founded by William the Conqueror and his Queen Matilda, with a particular history of the abbey of Bec, all written in French. The *History of the Royal Abbey of Bec*, which he presented to Dr Ducarel in 1764, is only an abstract of his larger work. This ancient abbey, which has produced several archbishops of Canterbury, and other prelates of England, is frequently mentioned by our old historians. The death of Bourget, which happened on new-year's day 1776, was occasioned by his unfortunate neglect of a hurt he had received in his leg by falling down two or three steps in going from the hall to the cloister of the abbey of St Stephen at Caen.

BOURGOING, JOHN FRANCIS DE, was born of an ancient family at Nevers, on the 20th November 1748. He was educated at the military school of Paris, and devoted himself particularly to the study of the languages. At the age of seventeen he was sent by the government to Strasbourg, where he studied public law under the celebrated Professor Kugler. Having spent three years there, he received a commission in the regiment of Auvergne. When scarcely twenty, he was appointed secretary of legation at the diet of Ratisbon; and after having been employed during four years in the discharge of various diplomatic functions, he returned to his regiment, where he continued to occupy himself with the study of public law. In 1777 he went as first secretary to M. de Montmorin, who was appointed ambassador to the court of Madrid. Eight years afterwards, Montmorin having been recalled, Bourgoing remained eighteen months at Madrid in the character of chargé d'affaires. It was during this long residence in Spain that he collected the materials for his *Tableau de l'Espagne Moderne*. On his return to France in 1787, he was sent as minister plenipotentiary to Hamburg; and, in 1791, he went in a similar capacity to Madrid, where he remained until the month of March 1793. Having again returned to France during the most troublesome period of the Revolution, he retired to his native town, where for some time he filled the first municipal office. The revolution of the 18th Brumaire (10th November 1799) drew him at length from the bosom of privacy. In 1801 the first consul appointed him minister plenipotentiary at the court of Denmark, and afterwards at that of Sweden. In 1808 he was sent as minister plenipotentiary to Saxony. At Dresden he was attacked by the complaint which terminated his life; and he died at Carlsbad, whither he had repaired for the benefit of the waters, on the 20th of July 1811, at the age of sixty-three.

Bourgoing was a man of the most disinterested integrity; and he died poor, although he had been employed in various situations in which he might have found opportu-

Bour-
guignons
||
Bourignon.

nities of acquiring wealth. He left a family of five children, three sons and two daughters. The following is a list of his publications: 1. *Nouveau Voyage in Espagne, ou Tableau de l'état actuel de cette Monarchie*, first published in 1789, 3 vols. 8vo. The fourth edition augmented, was published under the title of *Tableau de l'Espagne Moderne*, in 1807, in 3 vols. 8vo, with an atlas. This is the best known and most esteemed of his works, and has been translated into various languages. 2. *Mémoires Historiques et Philosophiques sur Pié VI. et sur son Pontificate*, 2 vols. 8vo, 1798; second edition, 1800. Some prefer the first edition of this work, although the second is continued to the death of Pius VI. 3. *Histoire des Flibustiers, traduite de l'Allemand de M. d'Archenholtz*, Paris 1804, 8vo. 4. *Histoire de l'Empereur Charlemagne, traduction libre de l'Allemand du Prof. Hegewisch*, 1805, 8vo. 5. *Correspondence d'un jeune Militaire, ou Mémoires du Marquis de Lusigny et d'Hortense de S. Just*, 1778, 2 vols. 12mo. Bourgoing translated some other works from the German, and published several tracts of little importance. In 1808 he published an edition of the *Travels of the Duc du Chatelet in Portugal*; and he was the editor of the *Correspondence of Voltaire with Bernis*. (κ.)

BOURGUIGNONS, or BURGUNDIANS, one of the northern nations who overran the Roman empire, and at length settled in Gaul. They were of great stature, and warlike in their disposition; for which reason the emperor Valentinian engaged them in his service against the Germans. They lived in tents, close to each other, that they might the more readily unite in arms on any unforeseen attack; and these conjunctions they called *burgs*, which were to them exactly what towns are to us. Sidonius Apollinaris tells us that they wore long hair, took great pleasure in singing, and were fond of praise for their vocal talents; that they ate enormous quantities, and anointed their hair with butter, deeming that unction extremely ornamental. Their crown was at first elective, and the authority of their kings expired with the occasion that had produced it. They were not only accountable for their own misconduct, but likewise for the accidents of nature and the caprice of fortune; being deposed if they lost a battle, or if they succeeded ill in any enterprise, or if any event did not correspond with the expectations of the public. Nor were they more favourably treated in case of a bad harvest or vintage, or in the event of an epidemical distemper ravaging the state. At first the Burgundians were governed by many kings, and *henden* was the title of the royal dignity. But in latter times they were subject to one sovereign, and became humane and civilized, especially when Christianity was propagated in their country. Before that epoch their religion was much the same with that of the other northern nations. They had many priests, the chief of whom was distinguished by the name of *sinistrus*. He was perpetual, and they paid him great respect and veneration.

BOURIGNON, ANTOINETTE, a famous female preacher and pretended prophetess, was born at Lisle in 1616. At her birth she was so deformed that it was debated some days in the family whether it would not be proper to stifle her as a monster; but her deformity diminishing, she was spared, and afterwards attained such a modicum of beauty, or rather so far diminished in ugliness, that she had her admirers. From her childhood to her old age she had an extraordinary turn of mind. She set up as a reformer, and published a great number of books filled with very singular notions; the most remarkable of which are entitled *The Light of the World*, and *The Testimony of Truth*. She was naturally an enemy to reason and common sense, which she maintained ought to give place to the illumination of divine faith; and asserted, that whenever any one was born again by embracing her doc-

trine, she felt the pains and throes of a woman in labour. Of her pretended visions and revelations there have been published many disgusting instances, which we shall not shock the reader by repeating. Besides these and other extravagancies, she had some very repulsive qualities. Her temper was morose and peevish, her cupidity excessive, her character as a woman questionable, and her habits eccentric and unfeminine. She dressed like a hermit, and travelled through France, Holland, England, and Scotland, where she made a strong party of some thousand sectarists, known by the name of *Bourignonists*. She died at Franeker in October 1680. Her principal works are, 1. Treatise on the Blindness of Men, and the Light born in Darkness; 2. The New Heaven and the Reign of Antichrist; 3. A Treatise on the Solid Virtue; 4. The Renewal of the Evangelical Spirit; and, 5. Innocence recognised and Truth discovered, addressed to the celebrated Arnauld. This strange woman pretended that the true church was extinct, and that God had commissioned her to re-establish it. The object of her works was to guide her followers to an imaginary perfection, and to make them renounce all forms in favour of an interior and mystic worship. Though possessed of a considerable fortune, to which she had succeeded, she never gave any thing to the poor, on the pretence that they might make a bad use of her liberality, and that the benefits we have received from God ought only to be employed for his greatest glory; a strange perversion of the charitable spirit of the gospel. Yet by an absurd though not unfrequent inconsequence of conduct, this woman bequeathed all her property to an hospital. Her mind was lively and acute, her style easy, and her eloquence seductive; endowments which enabled her to make, at different times, a considerable number of proselytes.

BOURNE, a market-town of the hundred of Aveland, in the county of Lincoln, 97 miles from London. It is situated in a pleasant country, very productive in corn and cattle; and is at the head of a fine stream, which runs to Spalding. The market is held on Saturday. The inhabitants amounted in 1801 to 1474, in 1811 to 1591, and in 1821 to 2029.

BOURO, an island in the East Indian Ocean, between the Moluccas and Celebes. It is well cultivated, and is now subject to the Dutch, who have built a fortress there. Some mountains in it are exceedingly high, and the sea on one side is uncommonly deep. It produces nutmegs and cloves, as well as cocoa and banana trees, besides many vegetables introduced by the Dutch. It is about 50 miles in circumference. Long. 129. E. Lat. 4. 30. S.

BOUSSAC, an arrondissement of the department of the Creuse, in France, extending over 370 square miles, and comprehending four cantons and fifty-seven communes, with 32,439 inhabitants. The capital is a market-town of the same name, at the junction of the rivers Benron and Creuse.

BOUTS-RIMES, a popular term in the French poetry, signifying certain rhymes, disposed in order, and given to a poet, together with a subject, to be filled up with verses ending in the same words, and in the same order. The invention of the bouts-rimés is ascribed to one Ducot, a poet, in the year 1649. In fixing the bouts, it is usual to choose such as seem the remotest, and have the least connection. Some good authors fancy that these rhymes are of all others the easiest; that they assist the invention, and furnish new thoughts. Sarrasin has a poem on the defeat of the bouts-rimés. But the academy of Lanternists at Toulouse contributed towards keeping in countenance the bouts-rimés, by proposing annually a set of fourteen, to be filled up on the glories of the Grand Monarque, and by offering a medal as the reward of the victorious sonneteer.

The following, filled up by Commire, is a specimen of these conceits :

*Tout est grand dans le roi, l'aspect seul de son
Rend nos fiers ennemis plus froids que des
Et Guillaume n'attend que le tems des
Pour se voir succomber sous un bras si
Qu'on ne nous vante plus les miracles d'
Louis de bien régner lui feroit des
Horace en vain s'égalé aux dieux dans ses
Moins que mon héros il étoit sage et*

BOUTON. See BOOTON.

BOUZIER, an arrondissement of the department of the Ardenne, in France, extending over 519 square miles, and comprehending eight cantons and 144 communes, with 56,157 inhabitants. The chief place is the market-town of the same name, on the banks of the river Aisne, which here forms two islands. The inhabitants are only about 1800.

BOVEY-TRACY, a market-town in the hundred of Teignbridge and county of Devon, 188 miles from London. It is remarkable for the production of a pipe-clay of great value in the potteries, and for a peculiar kind of coal. A court for the duchy of Lancaster is held here. The market is held on a Thursday. The inhabitants amounted in 1801 to 1431, in 1811 to 1485, and in 1821 to 1685.

BOW (*arcus*), a weapon of offence, made of wood, horn, or other elastic matter, which, being strongly bent by means of a string fastened to its two ends, throws out an arrow with great force in suddenly recovering its natural state. It is also called the *long-bow*, by way of distinction from the cross-bow or arbalest.

The bow is the most ancient and the most universal of all weapons. It has been found to obtain amongst the most barbarous and remote tribes, and it is an invention at once so obvious and so simple that no nation has missed it.

The use of the bow and arrow was first abolished in France under Louis XI. and in their place were introduced the Swiss arms, that is, the halberd, pike, and broadsword. The long-bow was formerly in great vogue in England; most of our victories in France were acquired by it, and many laws were made to regulate and encourage its use. The parliament under Henry VIII. complain "of the disuse of the long-bow, heretofore the safe-guard and defence of this kingdom, and the dread and terror of its enemies."

The art of using bows is called *archery*, and those practised therein are denominated *archers* or *bowmen*. See ARCHERY.

The strength of a bow may be calculated on this principle, that its spring, or the power whereby it restores itself to its natural position, is always proportional to the distance or space it is removed therefrom.

The most barbarous nations often excel in fabricating those things which they have the greatest necessity for in the common offices of life. The Laplanders, who support themselves almost entirely by hunting, have an art of making bows which we, in these more genial parts of the world, never arrived at. Their bow is constructed of two pieces of tough and strong wood, shaved down to the same size, and flattened on each side; the two flat sides of the pieces being brought closely and evenly together, and then joined by means of a glue made of the skins of perch, which they make superior in strength to ours. The two pieces, when once united in this manner, never separate, and the bow is of much more force to expel the arrow than it could possibly have been under the same dimensions if formed only of one piece.

Among the ancients, the bow-string was made of horse hair, and hence called *hippica*; though Homer's bow-strings were frequently made of hides cut into small thongs,

whence *roça Boia*. The uppermost part of the bow, to which the string was fastened, was called *νοβων*, being commonly made of gold, and the last thing towards finishing the bow. The Grecian bows were frequently beautified with gold or silver; whence *aurei arcus*, and the epithet of *Αργυροτοχος* bestowed on Apollo. But the matter of which they were ordinarily composed seems to have been wood, although they were anciently, Scythian-like, made of horn, as appears from the description of the bow of Pandarus in Homer.

The invention of the bow is usually ascribed to Apollo. And it was communicated to the primitive inhabitants of Crete, who are said to have been the first of mortals that understood the use of bows and arrows. Accordingly, even in later ages, the Cretan bows were famous, and preferred by the Greeks to all others. Some, however, preferred to honour Perses, the son of Persens, as the inventor of the bow; while others ascribe it to Scythus, son of Jupiter, and progenitor of the Scythians, who were excellent in this art, and by many reputed the first masters of it. From them it was derived by the Grecians, some of whose ancient nobility were instructed by the Scythians in the use of the bow, which in those days passed for a most princely education. It was first introduced into the Roman army during the second Punic war.

The Scythian bow was famous for its incurvation, which distinguished it from the bows of Greece and other nations, being so great as to form a half moon or semicircle; and hence the shepherd in Athenæus, describing the letters in Theseus's name, and expressing each of them by some apposite resemblance, compares the third to the Scythian bow, meaning not the more modern character Σ, but the ancient C, which is semicircular, and bears the third place in the name of the hero, ΘΗCEVC, as spelt in ancient Greek.

Cross-Bow is also called *arbalest* or *arbalet*, which word is derived from *arbalista*, or rather *arcubalista*, "a bow with a sling." The arbalet consists of a steel bow set in a shaft of wood, furnished with a string and a trigger; and it is bent with a piece of iron fitted for that purpose. It serves to project bullets, large arrows, darts, and other missiles. The ancients had large machines for throwing many arrows at once, called *arbalets* or *baliste*.

Bow, in *Ship-Building*. See SHIP-BUILDING.

Bow-NET or *Bow-wheel*, an engine for catching fish, chiefly lobsters and craw-fish. It is made of two round wicker baskets, pointed at the end, one of which is thrust into the other; while at the mouth is a little rim, four or five inches broad, and bent somewhat inwards. It is also used for catching sparrows.

Bow-LINE or *Bowling*, a rope fastened near the middle of the leech, or perpendicular edge of the square sails, by three or four subordinate parts called *bridles*. It is only used when the wind is so unfavourable that the sails must be all braced sideways, or close hauled to the wind. In this situation the bow-lines are employed to keep the weather or windward edges of the principal sails tight, forward, and steady, without which they would always be shivering, and rendered incapable of service. To *check* the bow-line is to slacken it when the wind becomes large.

Bow-PIECES are the pieces of ordnance at the bow of a ship.

Bow-BEARER, an inferior officer of the forest, who is sworn to make inquisition of all trespasses against vert or venison, and to attach offenders.

BOW ISLAND, in the South Pacific Ocean, is situated towards the eastern extremity of the Society Isles. It is a low-lying island, about ten or twelve leagues in compass, and has the extraordinary figure of a bow. Long. 141. 12. W. Lat. 18. 23. S.

Bow
Bow
Island.

Bower
||
Bowyer.

BOWER, in *Gardening*, a place under covert of trees, differing only from an arbour as being round or square, and made with a kind of dome or ceiling at top, whereas the arbour is always built long and arched.

BOWL denotes either a ball of wood for the use of bowling, or a vessel of capacity to contain liquors.

BOWLDER STONES, small stones of a roundish figure, and no determinate size, found on the sea-shore, and on banks, or rather channels, of rivers.

BOWLING, the art of playing at bowls. This game is practised either in open places, as bares and bowling-greens, or in close bowling-alleys.

The skill of bowling depends much on a knowledge of the ground, and the right choice of a suitable bowl; as for close alleys the flat bowl, while for green swards, plain and level, the bowl as round as a ball is preferred.

The terms used in bowling are, to *bowl wide*, which is when the bias does not hold, or is not strong enough; *narrow*, when it is too strong or holds too much; *finely bowled*, is when the ground is well chosen, and the bowl passes near the block, even though it goes much beyond it; *bowling through*, or a *yard over*, is done in order to move the block; an *over-bowl*, is that which goes beyond it; a *bowl laid at hand*, is that put down within the gamester's reach to be in the way of the next bowler, and hinder his having the advantage of the best ground; *bowling at length*, is neither bowling through nor short; a *dead length*, is a just or exact one; *throwing* or *flinging*, is discharging a bowl with a strength purposely too great for a length, in order to carry off either the block or some near bowl; *bowl-room*, or *missing wood*, is when a bowl has free passage without striking on any other; *get off*, is when a bowl, being narrow, is wanted to be wider; *bowl best at block*, is that nearest the block; and *drawing a cast or bowl*, is to win it by bowling nearer without stirring either the bowl or block. A bowl is said to *rub* when it meets with some obstacle in the ground which retards its motion and weakens its force; and *it is gone* when far beyond the block. *Block* signifies a little bowl laid for a mark, and is also called a *jack*. *Mark* is a proper bowling distance, not under so many yards, and being at least a yard and a half from the edge of the green; *ground*, is a bag or handkerchief laid down to mark where a bowl is to go; *lead* is the advantage of throwing the block and bowling first; *cast*, is one best bowl at an end; and *end*, is a hit, or when all the bowls are out. The *game*, or *up*, is five casts or best bowls.

BOWLING-GREEN, in *Gardening*, a kind of parterre in a grove, laid with fine turf, requiring to be frequently mowed, and laid out in compartments of divers figures, with dwarf-trees and other decorations. Bowling-greens are of English origin, but have been adopted by the French and Italians, who have them only for ornament, being unacquainted with or not fancying the exercise, on account of which they were first made in England.

BOWSPRIT, or **BOLTSPRIT**, a kind of mast, resting slopewise on the head of the main stern, and having its lower end fastened to the partners of the fore-mast, and further supported by the fore-stay. It carries the sprit-sail, sprit-top-sail, and jack-staff; and its length is usually the same with that of the fore-mast.

BOWYER, **WILLIAM**, the most learned printer of his age, was born at Whitefriars, in London, on the 17th December 1699. His father, whose name was also William, had been eminent in the same profession; and his maternal grandfather, Icabod Dawks, was employed in printing the celebrated Polyglot Bible of Bishop Walton. At a proper age he was placed for grammatical education under the care of Mr Ambrose Bonwicke, a nonjuring clergyman of piety and learning, who then lived at Headly, near Leatherhead, in Surrey. Here Mr Bowyer made great pro-

gress in literature, and a firm attachment commenced betwixt him and his master. On the 30th of January 1713 the whole property of the elder Mr Bowyer was destroyed by fire, on which occasion Mr Bonwicke generously undertook the education of his pupil for a year. In 1716 young Mr Bowyer was admitted a sizar at St John's College, Cambridge, where Dr Robert Jenkin was at that time master. He continued at the college under the tuition of the reverend Dr John Newcombe till June 1722, during which period he probably took his degree of bachelor of arts; and he appears to have been desirous of obtaining a fellowship, though it is not certain that he ever stood a candidate for that honour. Soon after this he had an opportunity of repaying the kindness which Mr Bonwicke had shown him, by officiating some time after his death in the capacity of schoolmaster for the benefit of his family.

Mr Bowyer now entered into the printing business along with his father. One of the first books which received the benefit of his correction was the complete edition of Selden, in three volumes folio, by Dr David Wilkins. This edition was begun in 1722, and finished in 1726; and Mr Bowyer's great attention to it appeared in his drawing up an epitome of Selden *de Synedriis*, as he read the proof sheets. In 1727 he drew up an excellent sketch of William Baxter's Glossary of Roman Antiquities, called "A view of a book entitled *Reliquiæ Baxterianæ*, in a letter to a friend." By this first public proof of Mr Bowyer's abilities, Dr Wotton and Mr Clarke were highly pleased; but as it was never published, and a very few copies printed, it is seldom found with the glossary. In 1727 Mr Bowyer lost his mother. In October 1728 he married Miss Ann Prudom, his mother's niece, a very accomplished lady, by whom he had two sons, William and Thomas; the former of whom died in nonage, and the latter survived his father. In 1729 Mr Bowyer published a treatise, entitled "A Pattern for young Students in the University, set forth in the Life of Ambrose Bonwicke, some time scholar of St John's College, Cambridge;" but although this treatise was generally ascribed to Mr Bowyer, it was in reality the production of Mr Ambrose Bonwicke the elder. About this time Mr Bowyer appears to have written a pamphlet against the Separatists, though neither the title nor the occasion of it are now remembered. The same year, through the friendship of the Right Honourable Arthur Onslow, he was appointed printer of the votes of the House of Commons; which office he held under three successive Speakers for near fifty years. In 1731 Mr Bowyer published, and, it is believed, translated, Voltaire's Life of Charles XII. This year also his wife died. He remained a widower till 1747, when he married a very benevolent and worthy woman, Mrs Elizabeth Bill, by whom he had no children. In 1733 he published a piece in two sheets 4to, entitled "The Beau and the Academic," being a translation from a Latin poem recited that year at the Sheldonian theatre; and in 1736 he was admitted into the Society of Antiquaries, where he became an active and useful member. In 1737 Mr Bowyer lost his father. In 1742 he published a translation of Trapp's Latin Lectures on Poetry, in which he was assisted by Mr Clarke, though the latter had a contemptible opinion of the performance.

In 1749 Mr Bowyer, along with Dr Burton, was virulently attacked by Dr King, in a piece entitled *Elogium famæ inserviens Jacci Etonensis sive Gigantis*, or the praises of Jack Eaton, commonly called Jack the Giant. This abuse was probably occasioned by Mr Bowyer's having hinted in conversation some doubts concerning the doctor's skill in Latin. He, however, drew up some strictures in his own defence, which he intended to insert at the end of a preface to Montesquieu's *Reflections*; but by

Mr Clarke's advice they were omitted. In 1750 a prefatory critical dissertation and some notes were annexed by our author to Kuster's Treatise *De usu Verborum mediocrum*; a new edition of which, with further improvements, appeared in 1773. He likewise wrote, about the same time, a Latin preface to Leede's *Veteres Poetæ citati*. Being soon after employed to print an edition of Colonel Bladen's translation of Cæsar's Commentaries, that work received considerable improvements from Mr Bowyer's hands, with the addition of notes signed TYPGR. In the subsequent editions of this work, though printed by another person during Mr Bowyer's lifetime, the same signature was unjustly retained. In 1751 he wrote a long preface to Montesquieu's *Reflections on the Rise and Fall of the Roman Empire*; translated the dialogue between Sylla and Socrates; and made several corrections on the work from the Baron's *Spirit of Laws*, improving it with notes of his own. A new edition, with many new notes, was printed in 1759. In 1751 he also published a translation of Rousseau's paradoxical oration, which gained the prize at the academy of Dijon in 1750, and first announced that singular genius to the attention and admiration of Europe. On the publication of the third edition of Lord Orrery's *Remarks on the Life and Writings of Dr Swift*, in 1752, Mr Bowyer wrote and printed, but never published, "Two Letters from Dr Bentley in the Shades below, to Lord Orrery in a Land of Thick Darkness." The notes signed B, in the ninth quarto volume of Swift's works, are extracted from these letters. In 1753 he endeavoured to allay the ferment occasioned by the Jews' Bill; and with this view he published, in quarto, "Remarks on the Speech made in Common Council, on the Bill for permitting persons professing the Jewish religion to be naturalized, so far as prophecies are supposed to be affected by it." This little tract was written with spirit, and well received by those who were superior to narrow prejudices. Its design was to show, that, whatever political reasons might be alleged against the bill, Christianity was in no danger of being prejudiced by the protection promised to the Jews. The same year some of Mr Bowyer's notes were annexed to Bishop Claton's translation of "A Journal from Grand Cairo to Mount Sinai and back again." In 1754 Mr Bowyer, with a view of lessening his fatigue, entered into partnership with a relation; but some disagreement arising, the connection was dissolved in three years. On the death of Mr Richardson in 1761, Mr Bowyer succeeded him as printer to the Royal Society, through the favour of the Earl of Macclesfield; and, under the friendship of five successive presidents, he enjoyed that office till his death.

In 1763 Mr Bowyer published an excellent edition of the Greek Testament, in two vols. 12mo. It appeared under the following title: *Novum Testamentum Græcum; ad fidem Græcorum solum Codicum MSS. nunc primum impressum, ad stipulante Joanne Jacobo Wetstenio, juxta Sectiones Jo. Alberti Bengelii divisum; et nova interpretatione sæpius illustratum: Accessere in altero volumine, Emendationes Conjecturales virorum doctorum undecunque collectæ*. This sold with great rapidity. The Conjectural Emendations were well received by the learned, and are thought to be a valuable work. The president and fellows of Harvard College in Cambridge expressed their approbation of this edition in very high terms, in a letter to Mr Bowyer, written in the year 1767. "This work," say they, "though small in bulk, we esteem as a rich treasure of sacred learning, and of more value than many large volumes of the commentators." A second edition of the Conjectures on the New Testament, with very considerable enlargements, was separately published in one volume 8vo in 1772. Bishop Warburton having censured a pas-

sage in the former edition, Mr Bowyer sent him a copy of this book, with a conciliatory letter. Dr Warburton's Divine Legation had received very considerable advantage from Mr Bowyer's corrections, and this even in an edition which was necessarily given to another press. In 1761 he was employed to print his lordship's Doctrine of Grace. A second edition being soon wanted, and Mr Bowyer not having been intrusted with the care of it, he prepared a series of letters to the bishop in his own defence; and of these, together with a few he had formerly received from that great writer, he afterwards printed *twelve copies*, of which *ten* were subsequently destroyed. However, there is the best authority for asserting, that notwithstanding any little altercations which happened, Dr Warburton always retained a sincere regard for our typographer. In 1765, at the request of Thomas Hollis, Esq. Mr Bowyer wrote a short Latin preface to Dr Wallis's *Grammaticæ Linguae Anglicanæ*. He wrote also a large English preface for the same work, which, however, was not printed. In 1766 he entered into partnership with Mr Nichols, who had been trained by him to the profession, and had for several years assisted him in the management of his business. The same year Mr Bowyer wrote a Latin preface to *Joannis Harduini, Jesuitæ, ad Censuram Scriptorum veterum Prolegomena*. In 1767 he was appointed to print the journals of the House of Lords and the rolls of Parliament. This year he printed Mr Clarke's excellent and learned work on *The Connection of the Roman, Saxon, and English Coins*, and wrote some notes upon it, which are interspersed throughout the volume with those of the author. Part of the Dissertation on the Roman sesterce was likewise Mr Bowyer's production; and the index, which is an uncommonly good one, was drawn up by him entirely.

In January 1771 Mr Bowyer lost his second wife. In the Philosophical Transactions of this year was printed a very ingenious *Inquiry into the Value of the ancient Greek and Roman Money*, by Mr Matthew Raper. But his opinions not coinciding with those of Mr Bowyer, the latter printed a small pamphlet, entitled *Remarks occasioned by a late Dissertation on the Greek and Roman Money*. In 1773 three little tracts were published by him, under the title of *Select Discourses*, treating, 1. Of the correspondence of the Hebrew months with the Julian, from the Latin of Professor Michaelis; 2. Of the Sabbatical years, from the same; 3. Of the years of Jubilee, from an anonymous writer in Masson's *Histoire Critique de la République des Lettres*. In 1774 he corrected a new edition of Schrevelius's Greek Lexicon; to which he added a number of words, which he himself had collected in the course of his studies. Considerable manuscript additions were also made by him to the lexicons of Hederic and Buxtorf, the Latin ones of Faber and Littleton, and the English Dictionary of Bailey; and he left behind him many other proofs of his critical skill in the learned languages. In 1774 was published *The Origin of Printing, in two Essays*. The original idea of this valuable tract was Mr Bowyer's, but it was completed by Mr Nichols.

Although our author, during the last ten years of his life, had been afflicted with the palsy and stone, he not only preserved a remarkable cheerfulness of temper, but was enabled to support the labour of almost incessant reading; and he regularly corrected the learned works, especially the Greek books, which came from his press. This he continued to do till within a few weeks of his death, which happened in November 1777, when he had nearly completed his seventy-eighth year. For more than half a century Mr Bowyer was unrivalled as a learned printer, and many of the most masterly productions of this kingdom issued from his press. To his literary and professional abilities he added an excellent moral charac-

Bowyers
||
Boxing.

ter; and he was particularly distinguished by his inflexible probity, and an uncommon alacrity in relieving the necessitous.

BOWYERS, artificers whose business is to make bows; in which sense bowyers are distinguished from fletchers, who made arrows. The bowyers' company in London was incorporated in 1620.

BOX, in its most common acceptation, denotes a small chest or coffer for containing articles.

Dice-Box, a narrow deep cornet, channelled within, by which the dice are shaken and thrown. This answers to what the Romans called *fritillus*. Besides the *fritillus*, the Romans, for greater security, had another kind of dice-box called *pyrgus*, *πυργος*, and sometimes *turricula*. It was placed immovably in the middle of the table, being perforated or open at both ends, and likewise channelled within; and over the top was fixed a kind of funnel, into which the dice were cast out upon the *fritillus*, and, descending, fell through the bottom on the table; by which all practising on them with the fingers was effectually prevented.

BOXERS, a kind of *athletæ*, who combat or contend for victory with their fists. Boxers are the same as the *pugiles* among the Romans. The ancient boxers battled with great force and fury, so as to dash out each other's teeth, break bones, and sometimes to kill each other. The disfigurements which the boxers underwent were such that they frequently could not be known, and were thus rendered the subject of many railleries. In the Greek Anthology there are four epigrams of the poet Lucilius, and one of Lucian, in which their disfigurements are pleasantly enough exposed.

BOXHORNIIUS, MARC ZUERIIUS, a learned critic, born at Bergen-op-Zoom in 1612, was professor of eloquence at Leyden, and at length of politics and history in the room of Heinsius. He published, 1. *Theatrum urbium Hollandiæ*, Amsterdam, 1632; 2. *Scriptores historiæ Augustæ, cum notis*, Leyden, 1632; 3. *Poetæ satyrici minores, cum commentis*, 1632; 4. Notes on Justin, Tacitus; and a great number of other works. He died in 1653, aged forty-one.

BOXING, the exercise of fighting with the fists, either naked or with a stone or leaden ball grasped in them. In this sense boxing coincides with the *pugillatus* of the Romans. When the champions had *σφαίραι*, or balls, whether of lead or stone, it was properly denominated *σφαίρομαχία*. The ancient boxing differed from the *pugna cæstum*, in which the combatants had leathern thongs on their hands, and balls to offend their antagonists withal; though this distinction is frequently overlooked, and fighting with the *cæstus* ranked as part of the business of *pugiles*. Three species of boxing may be distinguished, namely, where both the head and hands were naked; where the hands were armed and the head naked; and where the head was covered with a kind of cap, called *amphotides*, and the hands also furnished with the *cæstus*.

Boxing is an ancient exercise, having been in use in the heroic ages. Those who prepared themselves for it used all the means that could be contrived to render themselves fat and fleshy, that they might be the better able to endure blows. Hence corpulent men or women were usually

called *pugiles*, according to Terence. *Siqua est habilior paulo, pugilem esse aiunt.*

BOXING, among sailors, is used to denote the rehearsing the several points of the compass in their proper order.

BOXING is also used for the tapping of a tree, to make it yield its juice. The boxing of maple is performed by making a hole with an axe or chisel in the side of the tree, about a foot from the ground, that the liquor of which sugar is made may flow out through it.

BOYAR, a term used for a grandee of Transylvania, Wallachia, or Moldavia.

BOYAU, in *Fortification*, a ditch covered with a parapet, which serves as a communication between two principal trenches.

BOYCE, HECTOR, a distinguished historian, was born at Dundee about the year 1465, being descended of a family which for several generations had possessed the barony of Panbride or Balbride. The orthography of his surname is extremely fluctuating; it is to be found under the various modifications of Boece, Boeth, Boeis, Boys, Boyse, Boyes, Boyis, Boiss, and Boyce. The first of these, we strongly suspect, was never a name belonging to any living man in Scotland: it was formed by the French from the name of the latest Roman classic, and on that account appears to have been adopted by Bellenden in his translation of the history. The real Scottish name is a monosyllable; and we adhere to the orthography of Boyce, as being most common in our own time. He received the first rudiments of learning at Dundee, and completed his course of study in the university of Paris, where he took the degree of B. D. He was appointed a professor of philosophy in the College of Montaigu; and in this seminary he became intimately acquainted with Erasmus, who in two epistles has testified his esteem for Boyce's character.¹ In his academical station he had already distinguished himself by his talents and attainments, when King's College was founded at Aberdeen by the munificence of William Elphinstone, bishop of the diocese. The papal bull for the erection of a university had been obtained in the year 1494, but the buildings were not sufficiently advanced, nor did the lectures commence, till about the year 1500. It was not without some degree of hesitation that he consented to quit the lettered society of Paris, and to become principal of this new college; but having at length accepted the conditions, he proceeded to Aberdeen, and experienced a kind reception from the canons of the cathedral, several of whom he has commemorated as men of learning. It was a part of his duty as principal to read lectures on divinity. The sub-principal was his friend William Hay, a native of the same county, who had been his fellow-student at Dundee and at Paris, and who at length succeeded him as head of the college.² The principal's brother, Arthur Boyce, doctor of the canon, and licentiate of the civil law, was appointed professor of the canon law, and afterwards became a judge of the court of session.³ The common branches of science and literature were taught with zeal and success; and the prosperity of the institution was greatly promoted by the talents and by the reputation of Boyce.

The emoluments of his office were not such as appear

¹ *Erasmii Opera*, tom. i. tom. iii. col. 1784, edit. Clerici.—The first of these epistles introduces a catalogue of his own writings. Here his learned correspondent is named Hector Bæotius, nor has Dr Jortin subjoined his more common appellation. (*Life of Erasmus*, vol. ii. p. 725.)

² In Orem's *Description of King's College, Aberdeen*, p. 154-7, he is erroneously called William Gray.

³ Boyce has mentioned his brother in very favourable terms: "Arthurus Boetius, mihi germanus, in pontificio jure doctor, in civico (ut dicunt) licentiat, vir multæ doctrinæ, plus literarum indies consecutus, quod studium ei permanet animo indefesso, nobiscum jura pie et scite profitetur. Est in eo vis et gravitas eloquendi, a vulgari genere plurimum abhorrens. (*Abandonatum Episcoporum Vitæ*, p. 63. edit. Edinb. 1825, 4to.)

very dazzling to modern eyes. "Boethius, as president of the university," says Dr Johnson, "enjoyed a revenue of forty Scottish marks, about two pounds four shillings and sixpence of sterling money. In the present age of trade and taxes, it is difficult even for the imagination so to raise the value of money, or so to diminish the demands of life, as to suppose four and forty shillings a year an honourable stipend; yet it was probably equal, not only to the needs, but to the rank of Boethius. The wealth of England was undoubtedly to that of Scotland more than five to one, and it is known that Henry the Eighth, among whose faults avarice was never reckoned, granted to Roger Ascham, as a reward of his learning, a pension of ten pounds a year." But it is necessary to recollect that this was not the only preferment which Boyce enjoyed: he was not only principal of King's College, but was likewise a canon of Aberdeen, and rector of Tyrie in the same county. Under the date of July 14, 1527, we find a "grant to Maister Hector" of an annual pension of fifty pounds, to be paid by the sheriff of Aberdeen out of the king's casualties. And on the 26th of July 1529 was issued a "precept for a lettre to Mr Hector Boys, professor of theology, of a pension of L.50 Scots yearly, until the king promote him to a benefice of 100 marks Scots of yearly value; the said pension to be paid him by the customers of Aberdeen." In 1533 and 1534, one half of his pension was however paid by the king's treasurer, and the other half by the comptroller; and as no payment subsequent to that of Whitsuntide 1534 has been traced in the treasurer's accounts, he is supposed to have obtained his benefice soon after that period.²

His earliest publication, the lives of the bishops of Aberdeen, appeared under the subsequent title: "*Episcoporum Murthlacensium et Aberdonensium per Hectorem Boetium Vitæ.*" *Impressa sunt hæc prelo Ascensiano, ad Idus Maias anno Salutis M.D.XXII.* 4to. This little volume, which is of great rarity, was lately reprinted, for the members of the Bannatyne Club. "*Hectoris Boetii Murthlacensium et Aberdonensium Episcoporum Vitæ, iterum in lucem editæ.*" Edinb. 1825, 4to. Of the bishops of this diocese the seat was originally at Murthlack, in the county of Banff, but it was afterwards transferred to Aberdeen. His notices of the early prelates are necessarily brief and unsatisfactory, and the most interesting portion of the book is that which relates to his liberal patron Bishop Elphinstone; of whose private history and public services he has given a circumstantial detail, which occupies nearly one third of the volume. Here we likewise find an account of the foundation and constitution of the college, together with some notices of its earliest members.

His more famous work, the history of Scotland, was published after an interval of five years: "*Scotorum Historiæ a prima gentis origine, cum aliarum et rerum et gentium illustratione non vulgari: præmissa epistola nuncu-*

patoria, tabellisque amplissimis, et non pœnitenda Isagoge, quæ ab hujus tergo explicabatur diffusius. Quæ omnia impressa quidem sunt Iodoci Badii Ascensii typis et opera; impensis autem nobilis et prædocti viri Hectoris Boethii Deidonani, a quo sunt et condita et edita." Fol. The title and colophon have no date, but the commendatory epistle by Alexander Lyon, precentor of the cathedral of Elgin, bears the fifteenth of March 1527. This edition contains seventeen books. Another edition, containing the eighteenth book and a fragment of the nineteenth, was published by Ferrerius, who has added an appendix of thirty-five pages.³ Paris. 1574, fol. Though published at Paris, the latter edition appears from the colophon to have been printed at Lausanne.

The composition of Boyce's history displays much talent; and if the style does not always reach the standard of ancient purity, it displays a certain vein of elegance, which generally renders it attractive. The author's love of his native country, and his anxiety to emblazon the heroic deeds of his countrymen, are conspicuous in every part of the work; nor must we leave unnoticed those aspirations after political freedom, by which he was honourably distinguished at a period when the human mind was so generally chained to the earth by the most slavish maxims of submission. It may be recorded as commendation, instead of reproach, that his principles of polity have been represented as no better than those of Buchanan. Boyce's imagination was however stronger than his judgment: of the extent of the historian's credulity, his narrative exhibits many unequivocal proofs; and if this circumstance admits of a sufficient excuse from the common propensity of the age in which he lived, his work presents strong indications of another fault, for which it is not so easy to find an apology. According to Bishop Lloyd, he put Fordun's tales "into the form of an history, and pieced them out with a very good invention, that part in which he chiefly excelled."⁴ He professes to have obtained from the monastery of Icolmkill, through the good offices of the earl of Argyle and his brother the treasurer, certain original historians of Scotland, and among the rest Veremundus and Campbell, of whose writings not a single vestige is now to be found. In his dedication to the king, he is pleased to state that Veremundus, a Spaniard by birth, was archdeacon of St Andrews, and that he wrote in Latin a history of Scotland from the origin of the nation to the reign of Malcolm the Third, to whom he inscribed his work. According to Bishop Stillingfleet, whose opinion has been adopted by many other writers, these historians never existed except in Boyce's fertile imagination.⁵ From the charge of downright fabrication he has very recently been vindicated by Mr Maitland; but notwithstanding the ingenuity of the defence, we find it extremely difficult to divest ourselves of a strong impression, that the historian's account of his original materials, if not destitute of truth, is at least destitute of verisimilitude. His propensity to

³ Joannes Ferrerius, a native of Piedmont, resided for several years in Scotland under the patronage of Robert Reid, abbot of Kinloss, and afterwards bishop of Orkney. In the dedication of one of his works to this prelate, he mentions Hector and Arthur Boyce, together with several other scholars of Aberdeen. "*Aberdoniis rector a Kynkell, homo studiosus et politicus, me semper complexus est humanissime. Idem fecit Hector ille Boethius, historiarum vestrarum scriptor nunquam satis laudatus; ut interim omittam Arthurum Boethii fratrem germanum, utriusque juris peritissimum, Gulielmum Haye, theologum syncerum, ac Jacobum Vane, cum doctore medico peritissimo Roberto Gray. Adde his Joannem Vaus, virum cum literis tum moribus ornatissimum, et de juventute Scotica bene meritum.*" (*Auditum Visu præstare, contra vulgatum Aristotelis Placitum, academica Johannis Ferrerii Pædemoniani Dissertatio.* Paris. 1530, 4to.) With respect to his literary character, see Lord Hailes's *Examination of some of the Arguments for the high Antiquity of Regiam Majestatem*, p. 20. Edinb. 1769, 4to. Among various other works, he wrote a history of the abbots of Kinloss, which is printed, though not without abbreviation, in Martene and Durand's *Veterum Scriptorum et Monumentorum Collectio*, tom. vi.

⁴ Lloyd's *Historical Account of Church Government in Great Britain and Ireland*, pref.

⁵ Stillingfleet's *Antiquities of the British Churches*, p. 255.

Boyce. the marvellous¹ was at an early period exposed in the following tetrastich of Leland, which Dempster has erroneously ascribed to Humphrey Lhuyd:²

Hectoris historici tot quot mendacia scripsit,
Si vis ut numerem, lector amice, tibi,
Me jubeas etiam fluctus numerare marinos,
Et liquidi stellas connumerare poli.³

Lhuyd, who attacked him in different works, spoke of his fabrications without management or scruple;⁴ nor did he experience much better treatment from Stanihurst, an Irish writer of considerable reputation.⁵ Of his merits as an historian, a very unfavourable estimate has more recently been formed by Lord Hailes and Mr Pinkerton. But, in the opinion of Mr Wallace, a learned lawyer, his "elegant style and correct composition, not to add beautiful genius and fine fancy, are conclusive proofs that his understanding could not be inaccurate."⁶ And, as Mr Maitland has remarked, "in forming a final estimate of the literary character of Boece, we must bear in mind, that when scholar-craft, in this country at least, was rare, he was a scholar, and contributed, by reviving ancient learning, to dispel the gloom of the middle ages; and that, while the history of his country existed only in the rude page of the chroniclers who preceded him, or in the fading records of oral tradition, he embodied it in narrative so interesting, and language so beautiful, as to be worthy of a more refined age."⁷

Boyce's history of Scotland was translated into the Scottish language by John Bellenden, archdeacon of Moray and canon of Ross, of whom we have already presented our readers with a copious notice. While the learned archdeacon was engaged in translating the work into prose, another individual was engaged in the more formidable task of translating it into verse. A copy of this metrical version, containing about 70,000 lines, is preserved in the library of the university of Cambridge: a leaf seems to be wanting at the beginning, and the manuscript has suffered some other mutilations. The name of the versifier does not appear, nor has it been ascertained from any other document; but we learn from the prologue, that his labours, like those of Bellenden, were intended for the benefit of the young monarch. From the concluding lines, it is ascertained that he began his task in April 1531, and concluded it in September 1535. His verses are not distinguished by any considerable degree of energy or elegance, and the writer is chiefly to be commended for his perseverance. The prologue, which is unfortunately mutilated, contains an account of his motives for engaging in this laborious undertaking: it is conducted in the form of a dialogue between the translator and a certain lady, who is probably some allegorical personage. The following is perhaps the most curious passage which it contains.

Bot yit, scho said, I dreid in my intent
That to his grace it be ovir eloquent;
For quhy the termis poleist ar perfyte
Of eloquence, in rycht plesand indyte,
In Latene toung sententiouslie and schort,
Quhilk for to heir is plesand and confort.
Madame, I said, quha wes it drew that storie?
Ane man, scho said, of sic hie laud and glorie,
In Albione sen stories wes begun,
Wes nevir nane sic amang our poetis fun.
Madame, I said, quhat is that manniss name?
Ane Hector Boyis, said scho, of nobill fame,
Maister in art, doctor in theologie,
In all science ane profound clerk is he.
Madame, I said, now tell me or ye ga,
Quhat is the caus that ye commend it sua.
That sall I do, quoth scho, and yow wald heir.
Our old storeis befor thir mony yeir,
Tha war distroyit all with Inglismen
In Wallace weir, as it is eith to ken:
Syne efterwart quhen that tha wreit the storie,
Ald eldaris deidis to put into memorie,
Tha maid tha bukis, thair tractatis, and thair tabilis,
Part be ges, and part be fenzeit fabillis,
Part tha fand in ald bladis of bukis,
Part in lous quairis, liand wer in nukis:
Tha tuke sic cuir sic thingis to consider,
Syne in ane volume pat thame altogidder,
Without ordour, fassoun, or effect;
Mikill wantit, and all the lave suspect.
Madame, said I, now gar me vnderstand
Into quhat place that he tha stories fand.
That sall I do, than said scho, with gud will.
Intill ane place callit Ecolumkill,
Ane abbai sumtyme of authoritie,
In Iona yle, within the occident se,
Quhilk oft syis had of kingis corps the cuir;
Lang of the ald thair wes thair sepultuir:
And thair wes keptit thair storeis and bukis,
As in this libell yow sall se quhen yow luikis:
And in that place thair wes thair stories fand,
Sum in lous quairis, and uther sum weill band,
As Beid, Turgot, and Weremund alsua,
Corneill Campbell, and mony uther ma,
All tell and fynd ane fassoun and effect,⁸
In ornat spech, and nothing to suspect.
And for this caus I haif socht to ye heir:
Hartlie as now thair of, I ye requier,
Translait this libell in our mother toung,
And preis ye nocht my purpois to impugn.
The kingis grace I know is nocht perfyte
In Latyn toung, and namellie in sic dyte;
It wil be tedious, that dar I tak on hand,
To reid the thing he can not vnderstand:
War it translaid in our vulgar toung,
Out throw that realme the rumor [ould be roun].

In the year 1528, soon after the publication of his history, Boyce took the degree of D. D. at Aberdeen; and on this occasion the magistrates voted him a present of a tun of wine when the new wines should arrive, or, according

¹ One of the letters of Joseph Scaliger contains the subsequent passage relative to Boyce's story of the barnacles, or soland-geese: "Nam de conchis anatifera fabula prorsus est. Nullae enim anates ex conchis producuntur, sed ex putredine vetustorum navigiorum, quibus conchae adherent, anates quasdam nasci certum est. Etiam arbores anatiferas esse in ultima Scotia, ubi nullae prorsus arbores sunt, hactenus mentita est scriptorum vernilitas." (Scaligeri *Epistola*, p. 729. Lugd. Bat. 1627, 8vo.) See likewise Nicolai Nancelii *Analogia Microcosmi ad Macrocosmon*, col. 835. Lutetiae Paris. 1611, fol. It is just as easy to believe that birds grow upon trees as that they are produced from rotten wood; so that the philosophy of Scaliger seems to have conducted him but a little way beyond the region of absolute credulity.

² Dempsteri *Historia Ecclesiastica Gentis Scotorum*, p. 98. Bononiae, 1627, 4to.

³ Lelandi *de Rebus Britannicis Collectanea*, vol. v. p. 126.

⁴ "Ut hominem impurissimum suis depingam coloribus," says Lhuyd, "fucusque et praestigia quibus omnium oculis perstringere conatur, aperiantur, aliquas ejus vanissimas nugae, et omnibus cordatis pro mendaciis cognitae, leviter attingamus." (*Commentarii Britannicae Descriptionis Fragmentum*, f. 32, a. Col. Agrip. 1572, 8vo.) In another work, *De Mona Druidum Insula*, *Epistola*, he speaks in a similar strain: "Ut Hectoris Boethii innumera mendacia hinc facilius dignoscantur."

⁸ This line, which is scarcely intelligible, ought perhaps to have stood thus:

All hail and fyne in fassoun and effect.

to his option, the sum of twenty pounds to purchase a new bonnet.¹ He appears to have survived till the year 1536; for on the 22d of November in that year, the king presented John Garden to the rectory of Tyrie, vacant by the death of "Mr Hector Boiss." He died at Aberdeen, and, according to the most probable conjecture, he had then attained or at least approached the age of seventy. (x.)

BOYD, MARK ALEXANDER, a younger son of Robert Boyd of Pinkill in Ayrshire, was born on the 13th of January 1562. He is said to have come into the world provided with a couple of teeth. He learned the rudiments of the Latin and Greek languages at Glasgow under two grammarians, but was of so high and untractable a spirit, that they despaired of ever making him a scholar. Having quarrelled with his masters, he beat them both, burnt his books, and forswore learning. His uncle, James Boyd of Trochrig, was at that time archbishop of Glasgow; and, as he soon lost his father, his academical studies were conducted under the superintendence of this relation. After he entered the university, he was engaged in some very riotous proceedings, which have been particularly detailed by the able biographer of Melville. While he was yet a youth he followed the court, and exerted the usual means of obtaining preferment; but the fervour of his temper soon precipitated him into quarrels, from which he came off with honour and safety, though frequently at the hazard of his life. As he was nearly related to Lord Boyd, it is probable that he relied chiefly on his patronage; but, as Lord Hailes remarks, "all that we learn of his proficiency at court is, that he fought one duel, and was engaged in numberless broils." With the approbation of his friends, he went to serve in the French army, and carried with him his little patrimony, which he soon dissipated at play. He was shortly after roused by that emulation which is natural to superior minds, and applied himself to letters with unremitted ardour, till he attained to no mean proficiency as a scholar. Leaving his native country in 1581, when only in his twentieth year, he was not yet past the age of academical study; and he attended the lectures of several professors in the university of Paris, particularly those of Passerat, professor of eloquence, and of Genebrand, professor of Hebrew. Having next directed his attention to the civil law, he went to Orleans, and became a pupil of J. Robert, "a man principally known for having dared to become the antagonist of Cujacius." But from the university of Orleans he speedily removed to that of Bourges, where he is said to have obtained the friendship of Cujacius, by writing some verses in obsolete Latin; and, as one of his biographers has suggested, that learned man could not fail to relish verses which approached the standard of the twelve Tables.

The plague having driven him from Bourges, he sought a place of refuge at Lyon; and, when the infection extended to that city, he retired into Italy, where he contracted a friendship with a person whom he names Cornelius Varus. Having been seized with an ague, he returned to Lyon to try the effect of change of air; and the only regret which he felt in quitting Italy, is said to have arisen from his being thus deprived of the literary conversation and salutary advice of his friend. It was about the year 1585 that he revisited France. In 1587 he served with the royal forces opposed to the mercenary army of Germans and Swiss, which had invaded that country to support the king of Navarre. He served under an officer of cavalry, who was a Greek by birth; and,

during this campaign, he was wounded by a shot in the ankle. In 1588 he took up his abode in Toulouse, and applied himself to the study of the civil law under Roaldes, a professor of eminence. About the same period he appears to have written several tracts on the science of jurisprudence, and even to have projected a systematical work on the law of nature and nations. But his studies met with an unforeseen interruption, in consequence of the tumults which ensued at Toulouse, and during which the first president Duranty, the advocate-general Dafis, and other individuals of inferior quality, were murdered by the inhabitants. During this season of outrage Boyd was thrown into prison; and, as innocence afforded him no security, he was exposed to imminent danger of his life; but he owed his deliverance to the intercession of some of his friends. He now retired to Rochelle; but as the climate did not agree with his constitution, he afterwards fixed his residence at Fontenay in Poitou. In this retreat he devoted much of his time to study, and occasionally resumed the avocation of a soldier, for which he retained a violent propensity. He is reported to have acted as preceptor to a young French gentleman of the reformed religion, but of such an engagement his own writings communicate no information. About the year 1591 he appears to have formed a design of reading lectures on the civil law; and the heads of his prelections on the Institutes of Justinian are still preserved among his other papers in the Advocates Library.

His friends in Scotland, and among others Patrick Sharpe, under whom he had studied in the university of Glasgow, urged him to return to his native country; but, according to his own account, the state of his health had long obliged him to live obscurely in France, and his scanty circumstances would not allow him to make a tolerable figure in Scotland. He endeavoured however to strengthen his interest in his native land, by dedicating to James the Sixth a collection of his poems and epistles, printed at Antwerp, 1592, in 12mo. Three years afterwards, while preparing to return home, he received intelligence of the death of his elder brother William, for whom he apparently cherished a very sincere affection. Of his subsequent history, few particulars have been recorded. We are however informed that he at length returned to Scotland; and, after a short residence having undertaken to accompany the earl of Cassilis in his travels, he completed this engagement, and once more revisited his native country, where he died of a slow fever, on the 10th of April 1601. At the time of his death he was only in the fortieth year of his age.

Boyd appears to have been a person of a restless and turbulent disposition; and, as he added courage to strength, his sword must at least have been as formidable as his pen. He was tall, robust, and well-proportioned, and, possessing a handsome and pleasing countenance, he had much of the gallant bearing of a soldier. His literary vanity was not the least conspicuous part of his character. He was however a man of genius; and if his disposition and circumstances had been more favourable for persevering and systematical exertion, he might have secured a high reputation among the scholars of the age.²

BOYER, ABEL, a well-known glossographer and historiographer, born at Castres in France in 1664. Upon the revocation of the edict of Nantes, he went first to Geneva, then to Franeker, where he finished his studies, and finally came to England, where he applied himself so as-

Boyle.

siduously to the study of the English language, and made so great a proficiency therein, that he became an author of considerable note, and was employed in writing several periodical and political works. He was for many years concerned in a newspaper called the *Post-boy*, of which he had the principal management. He likewise published a monthly work entitled the *Political State of Great Britain*. He wrote a life of Queen Anne in folio, which is esteemed a very good chronicle of that period of the English history. But he is best known by a Dictionary and Grammar of the French language, which he compiled, and which are still reckoned good in their kind. He also wrote, or rather translated from the French of M. de Racine, the tragedy of Iphigenia, which he published under the title of *The Victim*. It was performed with success at Drury-Lane, and is very far from being a bad play. He died at Chelsea in 1729.

BOYER, in *Navigation*, a kind of Flemish sloop, or small vessel of burden, having a boltsprit, a castle at each end, and a tall mast, chiefly fitted for the navigation of rivers, and in many of its parts resembling a smack.

BOYLE, RICHARD, one of the greatest statesmen of the seventeenth century, and generally styled the Great Earl of Cork, was the youngest son of Mr Roger Boyle, and born at Canterbury on the 3d of October 1566. He studied at Bennet College, Cambridge, and afterwards became a student in the Middle Temple. Having lost his father and mother, and being unable to support himself in the prosecution of his studies, he became clerk to Sir Richard Manhood, one of the barons of exchequer; but finding that by his employment he could not improve his fortune, he went to Ireland in 1588 with fewer pounds in his pocket than he afterwards acquired thousands a year. He was then about twenty-two years of age, with a graceful person and many accomplishments, which enabled him to render himself useful to some of the principal persons employed in the government, by drawing up for them memorials, cases, and answers. In 1595 he married Jean, the daughter and co-heiress of William Ansley, who had fallen in love with him; and she, dying in 1599, left him an estate of £500 a year in land. In consequence of various services, and the great ability he displayed, he gradually rose to the highest offices, and even to the dignity of the peerage of Ireland, to which he was raised by King James I. on the 29th of September 1616, by the style and title of Baron of Youghall, in the county of Cork; four years after he was created Viscount Dungarvan and Earl of Cork; and in 1631 he was appointed lord-treasurer of Ireland, an honour that was made hereditary to his family. He particularly distinguished himself by the noble stand he made when the fatal rebellion broke out in Ireland in the reign of Charles I.; and in his old age he acted with as much bravery and military skill as if he had been trained from his infancy to the profession of arms. Having turned the castle of Lismore, his principal seat, into a fortress capable of demanding respect from the Irish, he immediately armed and disciplined his servants and Protestant tenants; and, with their assistance, and a small army raised and maintained at his own expense, which he put under the command of his four sons, he defended the province of Munster, took several strong castles, and killed upwards of three thousand of the enemy. During this time he paid his forces regularly; and when all his money was exhausted, he, like a true patriot, converted his plate into coin. He died on the 15th of September 1634.

BOYLE, Richard, Earl of Burlington and Cork, son of the former, was a nobleman of unblemished loyalty in troubled times, and of untainted integrity in a period of the greatest corruption. He was born at Youghall in October 1612, while his father was in the beginning of

his career, being then only Sir Richard Boyle; and he distinguished himself by his loyalty to King Charles I. He not only commanded troops, but raised, and, for a long time, paid them, continuing to wait upon the king as long as any place held out for him in England; and it was only in the last extremity he was forced to compound for his estate. He contributed all in his power to the Restoration; on which King Charles II. raised him to the dignity of Earl of Burlington or Bridlington, in the county of York, in the year 1663. He died in January 1697-8, in the eighty-sixth year of his age.

BOYLE, Roger, Earl of Orrery, younger brother of the former, and the fifth son of Richard, styled the Great Earl of Cork, was born in April 1621, and, by the credit of his father with the lord-deputy Falkland, was raised to the dignity and title of Baron Broghill when only seven years of age. He was educated at the college of Dublin, where he soon distinguished himself as an early and promising genius. He afterwards made the tour of France and Italy, and on his return assisted his father in opposing the rebellious Irish. Upon the execution of the king, he retired to Marston in Somersetshire, and buried himself in the privacy of a close retirement; but being at length ashamed to remain a tame spectator of what was passing around him, he resolved to attempt something in favour of the king; and under the pretence of going to the Spa for the recovery of his health, he determined to cross the seas and apply himself to King Charles II. for a commission to raise what forces he could in Ireland, in order to restore his majesty, and recover his own estate. For this purpose he prevailed on the Earl of Warwick to procure a license for his going to the Spa, and having raised a considerable sum of money, came up to London to prosecute his voyage. But he had not been long in town when he received a message from Cromwell, who was then general of the parliament's forces, intimating that he intended to wait upon him. The Lord Broghill was surprised at this message, having never had the least acquaintance with Cromwell; and desired the gentleman who brought it to let the general know that he would wait upon his excellency. But while he was waiting the return of the messenger, Cromwell entered the room, and after an exchange of civilities, told him in a few words that the committee of state were apprised of his design of going over and applying to Charles Stuart for a commission to raise forces in Ireland, and that they were determined to make an example of him, if he himself had not diverted them from that resolution. The Lord Broghill interrupted him by assuring him that the intelligence which the committee had received was false, and that he neither was in a capacity nor had any inclination to raise disturbances in Ireland; but Cromwell, instead of making any reply, drew some papers out of his pocket, being the copies of several letters which the Lord Broghill had sent to those persons in whom he most confided, and put them into his hands. Lord Broghill, upon the perusal of these papers, finding it to no purpose to dissemble any longer, asked his excellency's pardon for what he had said; returned him his humble thanks for his protection against the committee; and entreated his direction how to behave in such a delicate conjuncture. Cromwell told him, that though, till this time, he had been a stranger to his person, he was not so to his merit and character; he had heard how gallantly his lordship had behaved in the Irish wars; and therefore, since he was named lord-lieutenant of Ireland, and the reducing of that kingdom had now become his province, he had obtained leave of the committee to offer his lordship the command of a general officer if he would serve in that war; adding, that he should have no oaths or engagements imposed upon him, nor

be obliged to draw his sword against any but the Irish rebels.

Lord Broghill was infinitely surprised at so generous and unexpected an offer. He saw himself at liberty, by all the rules of honour, to serve against the rebellious Irish, whose barbarities were equally detested by the royal party and by the parliament. He desired, however, some time to consider of what had been proposed to him. But Cromwell briskly told him, that he must come to some resolution that very instant; that he himself was about to return to the committee, who were still sitting; and that if his lordship rejected their offer, they had determined to send him to the Tower. Upon this Lord Broghill, finding that his liberty and life were in the utmost danger, gave his word and honour that he would faithfully serve against the Irish rebels; upon which Cromwell once more assured him, that the conditions which he had made with him should be punctually observed, and then ordered him to repair to Bristol; adding, that he himself would soon follow him into Ireland. Lord Broghill, therefore, went over into that country, where, by his conduct and intrepidity, he performed many important services, and fully justified the opinion which Cromwell had conceived of him. By his own interest he raised a gallant troop of horse, which was soon increased to a regiment of 1500 men; and these he led into the field against the Irish rebels. He was speedily joined by Cromwell, who placed the highest confidence in his new ally, and found him of the greatest consequence to the interest of the commonwealth.

When Cromwell became Protector, he sent for Lord Broghill occasionally to take his advice. And we are told, that the latter, not long after his coming to England, formed a project for engaging Cromwell to restore the old constitution. The basis of the scheme was to be a match between the king, Charles II., and the Protector's daughter. As his lordship maintained a secret correspondence with the exiled monarch and his friends, it was imagined that he was beforehand pretty sure that Charles was not averse to the scheme, or he would not have ventured to propose it seriously to Cromwell, who at first seemed to think it not unfeasible. But the Protector soon changed his mind, and told Broghill that he thought his project impracticable: "For," said he, "Charles can never forgive me the death of his father." In fine, the business came to nothing, although his lordship had engaged Cromwell's wife and daughter in the scheme; but he never durst let the Protector know that he had previously treated with Charles about it.

On the death of the Protector, Lord Broghill continued attached to his son Richard, till, seeing that the honesty and good-nature of that worthy man would infallibly render him a prey to his enemies, he did not think it advisable to sink with a man whom he could not save. The dark clouds of anarchy seemed now to be gathering over the British island. Lord Broghill saw the storm preparing, and deemed it prudent to retire to his command in Ireland, where, shortly after, things took a turn extremely favourable to the design of the king's restoration. In this great event Lord Broghill was not a little instrumental; and, in consideration of his eminent services, Charles created him Earl of Orrery by letters-patent bearing date the 5th September 1660. He was soon after made one of the lords justices of Ireland; and his conduct, whilst at the head of affairs in that kingdom, was such as to add greatly to the general esteem in which his character was previously held.

His lordship's active and toilsome course of life at length brought on disease and infirmity; but notwithstanding these, on the king's desiring to see his lordship, he went over to England in 1665. He found the court

in some disorder, and his majesty on the point of removing the great Earl of Clarendon, lord high chancellor; and there also existed a misunderstanding between the royal brothers. Lord Orrery undertook to reconcile the king with the Duke of York; and this he effected by prevailing on the latter to ask his majesty's pardon for some steps which he had taken in support of the Lord Chancellor.

On his return to Ireland Lord Orrery found himself called to a new scene of action. The Dutch war was then at its height; and the French, in confederacy with the Hollanders, were endeavouring to stir up the ashes of rebellion in Ireland. The Duke de Beaufort, admiral of France, had formed a scheme for a descent upon Ireland; but this was rendered abortive by the extraordinary diligence, military skill, and prudent measures of Lord Orrery.

In midst of all his labours, a dispute, founded on mutual jealousy, arose betwixt him and his old friend the Duke of Ormond, then lord lieutenant; but the bad effects of it were soon felt by both disputants, who resorted to England to defend their respective interests and pretensions, and were attacked by secret enemies, who suggested many things to their prejudice. This quarrel, though of a private beginning, became at last of a public nature; and producing, first, an attempt to frame an impeachment against the Duke of Ormond, occasioned in the end, by way of revenge, an actual impeachment against the Earl of Orrery. But the latter defended himself so well against the charge of high crimes, and even of treason itself, that the prosecution came to nothing. He nevertheless lost his public employments; but retaining the king's favour, he still came frequently to court, and sometimes to council. After this revolution in his affairs, he made several voyages to and from Ireland, was often consulted by his majesty on affairs of the utmost consequence, and, on all occasions, gave his opinion and advice with the freedom of an honest plain-dealing man and a sincere friend.

In 1678, being attacked more cruelly than ever by his old enemy, the gout, he made his last voyage to England for medical advice. But his disorder was beyond the power of medicine; and having, in his last illness, given the strongest proofs of Christian patience, manly courage, and rational fortitude, he breathed his last on the 16th of October 1679, in the fifty-ninth year of his age. His lordship wrote, 1. A work entitled *The Art of War*; 2. *Parthenissa*, a romance, in one volume folio; 3. Several poems; 4. Dramatic pieces, in two volumes; 5. State tracts, in one volume folio; and some other pieces. Mr Walpole, speaking of this nobleman, says, he never made a bad figure but as a poet. As a soldier, his bravery was distinguished, his stratagems were remarkable; as a statesman, it is sufficient to say that he possessed the confidence of Cromwell; as a man he was grateful, and would have supported the son of his friend; but, like Cicero and Richelieu, he could not be content without being a poet, though ill qualified to shine in this character, and though his poetical writings were flat and trivial.

BOYLE, *Robert*, one of the greatest philosophers as well as best men that our own or indeed any other nation has produced, was the seventh son and the fourteenth child of Richard Earl of Cork, and was born at Lismore in the province of Munster in Ireland, on the 25th January 1626-7. Before he went to school, he was taught to write a very fair hand, and to speak Latin and French, by one of the earl's chaplains, and a Frenchman whom his lordship kept in the house. In the year 1635 his father sent him over to England, that he might be educated at Eton school, under Sir Henry Wotton, who was the Earl of Cork's old friend and acquaintance. Here he soon

Boyle.

Boyle discovered a force of understanding which promised great things, and a disposition to cultivate and improve it to the utmost. Whilst he remained at Eton, several very extraordinary accidents befel him, of which he has given us an account; and three of these were very near proving fatal to him. The first was the sudden fall of the chamber where he lodged, while he was in bed; when, besides the danger he incurred of being crushed to pieces, he had certainly been choked with the dust during the time he lay under the rubbish, if he had not had presence of mind enough to wrap up his head in the sheet, which gave him an opportunity of breathing without hazard. A little time after this he would have been crushed to death by a horse that reared suddenly, and threw himself backwards, if he had not happily disengaged his feet from the stirrups, and cast himself from the back of the animal before he fell. The third accident proceeded from the carelessness of an apothecary's servant, who, by mistaking the phials, brought him a strong emetic instead of a cooling medicine.

He remained at Eton, upon the whole, between three and four years; and then his father removed him to his own seat at Stalbridge in Dorsetshire, where he remained for some time under the care of one of the chaplains, who was the parson of the place. In 1638 he attended his father to London, and remained with him at the Savoy, till his brother Mr Francis Boyle espoused Mrs Elizabeth Killigrew; then, towards the end of October, within four days after the marriage, the two brothers, Francis and Robert, were sent abroad upon their travels, under the care of Mr Marcombes. Embarking at Rye in Sussex, they proceeded to Dieppe in Normandy, and travelled by Rouen to Paris, and thence to Lyons; from which city they continued their journey to Geneva, where their travelling companion had a family, and there pursued their studies without interruption. Mr Boyle, during his stay there, resumed his acquaintance with the mathematics, or at least with the elements of that science, of which he had before gained some knowledge.

In September 1641 he quitted Geneva, after having spent twelve months in that city, and, passing through Switzerland and the country of the Grisons, entered Lombardy; then, taking his route through Bergamo, Brescia, and Verona, he arrived at Venice, where he made a short stay, and returning to the Continent, spent the winter at Florence. Here he employed his spare hours in reading the modern history of Italy, and in studying the works of Galileo, who died in a village near this city during Mr Boyle's residence there. It was at Florence that he acquired the Italian language, which he understood perfectly, though he never spoke it so fluently as the French. Of the latter he was such a master, that, when occasion required, he passed for a native of France.

About the end of March 1642, he went from Florence to Rome, and surveyed the numerous curiosities of the Eternal City. Amongst these, he tells us, "he had the fortune to see Pope Urban VIII. at chapel, with the cardinals, who, severally appearing mighty princes, in that assembly looked like a company of common friars." He visited all the adjacent villages which had anything curious or antique belonging to them; and would probably have made a longer stay, had not the heats disagreed with his brother. He returned to Florence, thence proceeded to Leghorn, and so by sea to Genoa; then passing through the county of Nice, he crossed the sea to Antibes, and thence travelled by land to Marseilles. He was in that city in May 1642, when he received his father's letters, informing him that a rebellion had broken out in Ireland, and with what difficulty he had procured the L.250 then remitted to them in order to defray the expenses of their journey home. They never received this sum; and were

obliged to repair to Geneva with their governor Marcombes, who supplied them with as much as carried them thither. They continued there a considerable time without either advice or supplies from England; upon which Marcombes was obliged to take up, upon his own credit, some jewels, which were afterwards disposed of with as little loss as might be; and with the money thus raised they continued their journey to England, where they arrived in the year 1644. On their arrival Mr Boyle found that his father was dead; and though the earl had made ample provision for him, by leaving him the manor of Stalbridge in England, as well as other considerable estates in Ireland, yet it was some time before he could receive any money. However, he procured protections for his estates in both kingdoms from the powers then in being; and he also obtained leave to go over to France for a short space, probably to settle accounts with his governor Mr Marcombes.

In March 1646 he retired to his manor at Stalbridge, where he resided for the most part till May 1650. He made excursions sometimes to London, sometimes to Oxford; and in February 1647 he went over to Holland, but made no considerable stay anywhere. During his retirement at Stalbridge he applied himself with incredible industry to studies of various kinds, particularly to those of natural philosophy and chemistry. He omitted no opportunity of making the acquaintance of persons distinguished for parts and learning, to whom he was always a ready, useful, and generous assistant, and with whom he maintained a constant correspondence. He was also one of the first members of that small but learned body of men which, when all academical studies were interrupted by the civil wars, secreted themselves, about the year 1645, and held private meetings, first in London, and afterwards at Oxford, for the purpose of canvassing subjects of natural knowledge upon the plan of experiment which Lord Bacon had delineated. They then styled themselves the Philosophic College; and after the Restoration, when they were incorporated and openly recognised, they took the name of the Royal Society.

In the summer of 1654 Mr Boyle executed a design which he had formed for some time of residing at Oxford. Oxford was indeed the only place at that time in England where he could have lived with much satisfaction; for here he found himself surrounded with a number of learned friends, such as Wilkins, Wallis, Ward, Willis, Wren, and others, suited exactly to his taste, and who had resorted thither for the same reasons as himself. It was during his residence here that he improved the air-pump, and by numerous experiments was enabled to discover several qualities of air. He was not satisfied with what he had done, however, but laboured incessantly in collecting and digesting, chiefly from his own experiments, the materials requisite for his purpose. He declared against the philosophy of Aristotle, as having in it more words than things, as promising much and performing little, and as giving the inventions of men for indubitable proofs, instead of building upon observation and experiment. He was so zealous for the true method of learning by experiment, that though the Cartesian philosophy then made a great noise in the world, yet he could never be persuaded to read the works of Descartes, lest he should be amused and led away by plausible accounts of things founded on conjecture, and merely hypothetical. But philosophy, and inquiries into nature, though they engaged his attention deeply, did not occupy it entirely. We find, indeed, that he still continued to pursue critical and theological studies. In these he had the assistance of some great men, particularly Dr Edward Pococke, Mr Thomas Hyde, and Mr Samuel Clarke, all of great emi-

nence for their skill in the oriental languages. He had also a strict intimacy with Dr Thomas Barlow, at that time head keeper of the Bodleian library, and afterwards Bishop of Lincoln, a man of various and extensive learning. In the year 1659 Mr Boyle, becoming acquainted with the unhappy circumstances of Saunderson, afterwards bishop of Lincoln, who lost all his preferments on account of his attachment to the royal party, conferred upon him an honorary stipend of £50 a year. This was given to encourage him to apply himself to the writing of "Cases of Conscience;" and accordingly he printed his lectures *De Obligatione Conscientiæ*, which he read at Oxford in 1647, and dedicated to his friend and patron.

On the restoration of Charles II. Mr Boyle was treated with great civility and respect by the king, as well as by the Lord Treasurer Southampton, and the Lord Chancellor Clarendon. He was solicited by the latter to enter into holy orders, not only out of regard to him and his family, but chiefly with a view to serve the church itself; for Mr Boyle's noble family, his distinguished learning, and, above all, his unblemished reputation, induced Lord Clarendon to think that any ecclesiastical preferments he might attain would be worthily discharged, so as to do honour to the clergy and service to the established communion. Mr Boyle considered all this with due attention; but he also reflected, that, in the situation of life which he then occupied, whatever he wrote with respect to religion would have much greater weight as coming from a layman; that, in point of fortune, he needed no accessions, and indeed never had any appetite for such; and that, by taking orders, he would neither enhance his character nor enlarge the sphere of his usefulness, but rather the reverse. He chose, therefore, to pursue his philosophical studies in such a manner as might conduce to the support of religion, and began to communicate to the world the fruits of these studies.

The first of these were printed at Oxford in 1660, in 8vo, under the title of *New Experiments, Physico-mechanical, touching the Spring of the Air and its Effects; and Seraphic Love, or some Motives and Incentives to the Love of God*, pathetically discoursed of in a letter to a friend. Certain physiological essays and other tracts, in 4to, appeared in 1661; and the *Sceptical Chemist*, in 1662, but it was reprinted about the year 1679, in 8vo, with the addition of divers experiments and notes.

In the year 1663, the Royal Society having been incorporated by King Charles II., Mr Boyle was appointed one of the council; and as he might be justly reckoned among the founders of that learned body, so he continued one of the most useful and industrious of its members during the whole course of his life. In June 1663 he published *Considerations touching the usefulness of Experimental Natural Philosophy*, 4to, and *Experiments and Considerations upon Colours*; to which was added, a Letter, containing *Observations on a Diamond that shines in the Dark*, 8vo. This treatise, which is full of curious and useful remarks on the hitherto unexplained doctrine of light and colours, shows great judgment, accuracy, and penetration; and it may be said to have led the way to that more full and ample development of the subject which was reserved for the mighty genius of Sir Isaac Newton. *Considerations on the style of the Holy Scriptures*, in octavo, also appeared in 1663, and was an extract from a larger work, entitled *An Essay on Scripture*, which was afterwards published by Sir Peter Pett, a friend of Mr Boyle's.

In 1664 he was elected into the company of the royal mines, and all this year he was engaged in the prosecution of various good designs, which prevented his sending abroad any treatises either of religion or philosophy. The year following came forth *Occasional Reflections upon se-*

veral Subjects, 1665, 8vo. This piece is addressed to *Sophronia*, under which name he concealed that of his sister the Viscountess of Ranelagh, and it exposed him to the only severe censure that ever was passed upon him. In order to ridicule these discourses, Dean Swift wrote *A Pious Meditation upon a Broomstick, in the style of the Honourable Mr Boyle*. But, as his noble relative Lord Orrery observed, "To what a height must the spirit of sarcasm arise in an author, who could prevail on himself to ridicule so good a man as Mr Boyle? The sword of wit, like the scythe of time, cuts down friend and foe, and attacks every object that lies in its way. But, sharp and irresistible as the edge of it may be, Mr Boyle will always remain invulnerable."

The same year he published an important work, entitled *New Experiments and Observations upon Cold*, 1665, 8vo. In the year 1666 he published *Hydrostatical Paradoxes* made out by new Experiments, for the most part physical and easy, in 8vo; and also the *Origin of Forms and Qualities*, according to the *Corpuscular Philosophy*, illustrated by considerations and experiments. This last treatise did great honour to Mr Boyle, whether we consider the quickness of his wit, the depth of his judgment, or his indefatigable pains in searching after truth. But we must not forget to observe, that, both in this and the former year, he communicated to Mr Oldenburg, secretary to the Royal Society, several curious and excellent short treatises of his own, and others transmitted to him by his learned friends both at home and abroad, which are printed and preserved in the *Philosophical Transactions*.

In the year 1668, Mr Boyle, having resolved to settle in London for life, removed for that purpose to the house of his sister, the Lady Ranelagh, in Pall-Mall. This proved beneficial to the learned in general, and particularly to the Royal Society, to whom he gave great and continual assistance, as the several pieces communicated to them, and printed in their *Transactions*, abundantly testify. Those who applied to him, either to desire his help or to communicate any new discoveries in science, he had fixed hours for receiving; and, besides, he carried on an extensive correspondence with persons of learning in all parts of Europe. In the year 1669 he published *A Continuation of New Experiments, touching the Weight and Spring of the Air*; to which is added, *A Discourse of the Atmospheres of Consistent Bodies*: and the same year he revised and made many additions to several of his former tracts, some of which were now translated into Latin, in order to gratify the curious abroad. He also gave to the world, at this time, *Tracts about the Cosmical Qualities of Things, the Temperature of the Subterraneous Regions, and the Bottom of the Sea*; to which is prefixed, an *Introduction to the History of Particular Qualities*. This book occasioned much speculation, as it seemed to contain a vast treasure of knowledge which had never before been communicated to the world, and which, too, was grounded upon actual experiments, or arguments justly drawn from them, instead of that notional and conjectural philosophy which in the beginning of the seventeenth century had been so much in fashion.

In the year 1671 he published *Considerations on the Usefulness of Experimental and Natural Philosophy* (part second), 4to; and, *A Collection of Tracts upon several useful and important points of Practical Philosophy*, 4to; both of which works were received as new and valuable gifts to the learned world. An essay concerning the *Origin and Virtues of Gems*, 8vo, appeared in 1672; also, *A collection of tracts upon the relation between flame and air, and several other useful and curious subjects*; besides which he furnished, in this and the former year, a great number of short dissertations upon a variety of topics, addressed to

Boyle. the Royal Society, and inserted in their Transactions. Essays on the strange Subtlety, great Efficacy, and determinate Nature of Effluvia, to which were added a variety of Experiments on other Subjects, came out in 1673, 8vo. A collection of tracts upon the saltness of the sea, the moisture of the air, the natural and preternatural state of bodies, to which is prefixed a dialogue concerning cold, was published in 1674, 8vo. The excellency of theology, compared with philosophy, appeared in 1673. This discourse was written in the year 1665, while Mr Boyle, to avoid the great plague which then raged in London, was forced to wander from place to place in the country, and had little or no opportunity of consulting books. It contains a great number of curious and useful, as well as just and natural observations. A collection of tracts containing suspicions respecting hidden qualities of the air, with an appendix touching celestial magnets, animadversions upon Mr Hobbes's problem about a vacuum, and a discourse of the cause of attraction and suction, was published in 1674; and some considerations about the reconcileableness of reason and religion, by a layman; to which is annexed a discourse about the possibility of the resurrection, appeared in 1655. Both these pieces were of his composition; but he thought fit to mark the former with the final letters of his name. Amongst the papers which he communicated to the Royal Society this year, were two connected into one discourse; the one entitled An experimental discourse of quicksilver growing hot with gold; the other relating to the same subject; and both of them containing discoveries of the utmost importance.

In the year 1676 he published Experiments and Notes about the mechanical origin or production of particular qualities, in several discourses on a great variety of subjects, and, among the rest, on electricity. In 1678 he communicated to Mr Hooke a short memorial of some observations made upon an artificial substance that shines without any preceding illustration; which that gentleman thought fit to publish in his *Lectiones Cutlerianæ*. His historical account of a degradation of gold produced by an anti-elixir, made a great noise both at home and abroad, and is looked upon as one of the most remarkable pieces that ever fell from his pen; since the facts contained in it would have been esteemed incredible, if they had been related by a man of less integrity and piety than Mr Boyle. The regard which Newton had for Mr Boyle appears from a letter which the former wrote to him, towards the close of this year, stating his sentiments of that ethereal medium which he afterwards considered in his *Optics* as the cause of gravitation. This letter is to be found in the life of Mr Boyle by Dr Birch.

In the year 1680, Mr Boyle published the Aerial Noctiluca, or some new phenomena, and a process of a factitious self-shining substance, 8vo. This year the Royal Society, as a proof of their sense of his great worth, and of the services which, throughout a course of years, he had rendered them, elected him as their president; but being extremely sensitive in regard to oaths, he declined the intended honour, in a letter addressed to "his much respected friend Mr Robert Hooke, professor of mathematics at Gresham College." He published a Discourse

of things above Reason, inquiring, whether a philosopher should admit any such, 1681, 8vo; New Experiments and Observations upon the icy Noctiluca, to which is added a chemical paradox, grounded upon new Experiments, 1682, 8vo; and a continuation of New Experiments, Physico-mechanical, touching the spring and weight of the air, 1682, 8vo. In 1683 he published nothing except a short letter to Dr Beale, in relation to the making of fresh water out of salt; but in 1684 he gave to the public two very considerable works, namely, Memoirs for the natural history of Human Blood, especially the spirit of that liquor, 8vo; and Experiments and Considerations about the porosity of bodies.

In 1685 Mr Boyle obliged the world with Short Memoirs for the natural experimental history of Mineral Waters, with directions as to the several methods of trying them; an essay on the great effects of even languid and unheeded motion, which was received with great and general applause; a treatise of the Reconcilableness of specific medicines to the Corpuscular Philosophy, to which is annexed a discourse about the advantages of the use of simple medicines, 8vo; and a theological tract of the high veneration man's intellect owes to God, peculiarly for his wisdom and power, 8vo.

In the beginning of the succeeding year came out his Free Inquiry into the vulgarly received notion of Nature, a piece which was greatly admired; and in 1687 he published the martyrdom of Theodora and Didymia, a juvenile performance. But his Disquisition about the final causes of natural things, in 8vo, appeared in 1688.

Mr Boyle now began to find that his health and strength, notwithstanding all his care and caution, gradually declined; a circumstance which put him upon using every possible method of husbanding his remaining time for the benefit of the learned. With this view he no longer communicated particular discourses or new discoveries to the Royal Society, because it could not be done without withdrawing his thoughts from occupations which he thought of still greater importance. In order the more steadily to attend to these, he resigned his post of governor of the corporation for propagating the gospel in New England; and even went so far as to signify to the world, by public advertisement,¹ that he could no longer receive visits as usual.

Among the other works which by this means he gained time to finish, there is reason to believe that one was a collection of elaborate processes in chemistry, concerning which he wrote a letter to a friend, stating, that "he left it as a kind of hermetic legacy to the studious disciples of that art." Besides these papers, which were committed to the care of one whom he esteemed his friend, he left many behind him at his death relating to chemistry, which, by a letter directed to one of his executors, he desired might be inspected by three physicians whom he named, and that some of the most valuable might be preserved.

In the meantime Mr Boyle published some other works, as *Medicina Hydrostatica*, or, Hydrostatics applied to the Materia Medica, 1690, 8vo; *The Christian Virtuoso*, to which are subjoined, A discourse about the distinction that represents some things as above reason, but not con-

¹ This curious intimation begins in the following manner:—"Mr Boyle finds himself obliged to intimate to those of his friends and acquaintance that are wont to do him the honour and favour of visiting him, 1. That he has by some unlucky accidents, namely, by his servant's breaking a bottle of oil of vitriol over a chest which contained his papers, had many of his writings corroded here and there, or otherwise so maimed, that, without he himself fill up the lacunæ out of his memory or invention, they will not be intelligible; 2. That his age and sickness have for a good while admonished him to put his scattered and partly defaced writings into some kind of order, that they may not remain quite useless; and, 3. That his skilful and friendly physician, Sir Edmund King, seconded by Mr Boyle's best friends, has pressingly advised him against speaking daily with so many persons as are wont to visit him, representing it as what cannot but waste his spirits," &c. He ordered likewise a board to be placed over his door, with an inscription signifying when he did, and when he did not, receive visitors.

Boyle

trary to reason; and the first chapters of a discourse entitled *Greatness of mind promoted by Christianity*. Lastly, he published, in the spring of 1691, *Experimenta et Observationes Physicæ*, treating of several subjects relating to natural philosophy, in an experimental way, 8vo.

About the beginning of summer he began to feel such an alteration in his health as induced him to think of settling his affairs; and accordingly, on the 18th of July he signed and sealed his last will, to which he afterwards added several codicils. In October his distemper increased; and on the last day of December 1691 he departed this life, in the sixty-fifth year of his age. He was buried in St Martin's Church in the Fields, Westminster, on the 7th of January following; and his funeral sermon was preached by Dr Gilbert Burnet, bishop of Salisbury. In this discourse the bishop tells us, that he was the better able to give a character of the deceased from the many happy hours he had spent in conversation with him in the course of twenty-nine years. He gives a large account of Mr Boyle's sincere and unaffected piety, more especially of his zeal for the Christian religion, without having any narrow notions concerning it, or mistaking, as so many do, a bigoted heat in favour of a particular sect, for that zeal which is an ornament of a true Christian; and he mentions as a proof of this, his noble foundation for lectures in defence of the gospel against infidels of all sorts. Mr Boyle was at the charge of the translation and impression of the New Testament into the Malayan tongue, which he sent over all the East; he gave a noble reward to the person who translated Grotius's book *On the Truth of the Christian Religion* into Arabic; and he was at the charge of a whole impression, which he took care to have distributed in all the countries where that language was understood. He had resolved to have carried on the impression of the New Testament in the Turkish language; but the Levant Company thought it became them to be the promoters of the design, and so suffered him only to contribute largely towards it. He expended £700 on the edition of the Irish Bible, which he ordered to be distributed in Ireland; and he contributed liberally to the impression of the Welsh Bible. He gave, during his life, £300 to advance the design of propagating the Christian religion in America; and as soon as he heard that the East India Company were entertaining propositions for a similar design in the East, he sent £100 as a beginning and an example, intending, however, to extend his contribution as soon as the scheme had been fairly commenced. In other respects his charities were so bountiful and extensive, that they amounted to upwards of £1000 a year. Of his merits as an inquirer into nature, Dr Boerhaave, after declaring Lord Bacon to be the father of experimental philosophy, says, that "Mr Boyle, the ornament of his age and country, succeeded to the genius and inquiries of the great Chancellor Verulam. Which (he adds) of Mr Boyle's writings shall I recommend? All of them. To him we owe the secrets of fire, air, water, animals, vegetables, fossils; so that from his works may be deduced the whole system of natural knowledge." This may now appear extravagant and exaggerated; but at the time it was not unreasonably considered as only a just tribute to extraordinary merit and indefatigable perseverance.

In his person Mr Boyle was tall, but slender; and his countenance was pale and emaciated. His constitution was so delicate, that he had divers sorts of cloaks to put on when he went abroad, according to the temperature of the air; and in this he governed himself by the thermometer. He escaped the small-pox indeed; but for nearly forty years he laboured under such feebleness of body, and such depression of strength and spirits, that it is astonishing how he could read, meditate, make experiments, and write, as

he did. He had likewise a weakness in his eyes, which made him very tender of them, and extremely apprehensive of such distempers as might affect them. He also imagined, that if sickness should confine him to bed, it might increase the pains of the stone to a degree above his strength to support; and this was the ground of the caution with which he was observed to live. But as to life itself, he had that just indifference for it which became a philosopher and a Christian. Mr Boyle was never married. In the memorandum of his life set down by Bishop Burnet, it is remarked that he abstained from marriage, at first out of policy, but afterwards more philosophically; and we find from a letter of Dr John Wallis to him, dated Oxford, 17th July 1669, that he had had an overture made to him in regard to the Lady Mary Hastings, sister to the Earl of Huntingdon. But it does not appear from any of his papers that he had ever entertained the least thoughts of the kind; and there is a letter of his, written when he was young to Lady Barrymore, his niece, which almost shows that he never did.

We shall conclude this account of Mr Boyle with a list of his posthumous works, which are as follow: 1. The General History of the Air designed and begun; 2. General Heads for the Natural History of a Country, great or small, drawn out for the use of Travellers and Navigators; 3. A paper of the honourable Robert Boyle's, deposited with the secretaries of the Royal Society, October 14, 1680, and opened since his death, being an account of his making the phosphorus, September 30, 1680; 4. An Account of a way of examining Waters as to Freshness or Saltness; 5. A free Discourse against customary Swearing, and a Dissuasive from Cursing, 1695, 8vo; and 6. Medicinal Experiments, or a Collection of choice remedies, chiefly simple and easily prepared, useful in families, and fit for the service of the country people; being the third and last volume published from the author's original manuscript, 1698, 12mo. Editions of all his works have been printed at London, in five volumes folio, and six volumes 4to.

BOYLE, *Charles*, Earl of Orrery in Ireland, and Baron of Maston in the county of Somerset, was the second son of Roger second Earl of Orrery, and was born in August 1679. He was educated at Christ Church, Oxford, and soon distinguished himself by his learning and abilities. Like the first Earl of Orrery, he was an author, a soldier, and a statesman. He translated the life of Lysander from the Greek of Plutarch; and he published a new edition of the epistles of Phalaris, which engaged him in a literary dispute, in which he defended the genuineness of those epistles against Dr Bentley. He was three times member for the town of Huntingdon; but his elder brother, Lionel Earl of Orrery, dying without issue on the 23d of August 1703, he succeeded to that title; and, entering into the queen's service, obtained a regiment, upon which he behaved with so great bravery, that, in 1709, he was raised to the rank of major-general, and sworn one of her majesty's privy-council. At the battle of the Wood he gave the strongest proofs of intrepid courage, remaining at the head of his regiment in the hottest part of the action till the victory was decided. His lordship had the honour of being appointed the queen's envoy to the states of Brabant and Flanders; and having honourably discharged this trust, he was raised to the dignity of British peer, by the title of Lord Boyle, Baron of Maston, in Somersetshire. He received several additional honours in the reign of King George I.; but having had the misfortune to fall under the suspicion of the government, he was committed to the Tower, and remained there some time in confinement. He was at length admitted to bail, however; and nothing being found that could be regarded

Boyle.

Boyle. as sufficient ground for prosecution, he was discharged. His lordship died, after a slight indisposition, on the 21st of August 1731. To his tutor Mr Atterbury he probably owed in good part the relish he possessed for the writings of the ancients. He made these his constant study, and seems to have entertained a very unreasonable degree of contempt for the greater part of our modern wits and authors. His lordship had also a turn for medicine, which led him not only to buy and read whatever was published on that subject, but also to employ his friends to send him accounts of herbs and drugs from foreign countries.

BOYLE, *John*, Earl of Cork and Orrery, a nobleman distinguished for his learning and genius, was the only son of Charles Earl of Orrery, and was born on the 2d of January 1707. He was educated at Christ Church College, Oxford; but, as he himself declares, early disappointments, indifferent health, and many untowards accidents, rendered him fond of retirement, and of improving his talents for polite literature and poetry. Of these he has left several favourable specimens. He also wrote a translation of the Letters of Pliny the Younger, with various notes, for the service of his eldest son Lord Boyle, in two volumes 4to. This was first published in 1751. The year following he published the Life of Dean Swift, in several letters, addressed to his second son Hamilton Boyle; and he afterwards printed Memoirs of Robert Cary, Earl of Monmouth, a manuscript presented to him by a relation, with explanatory notes. He died in 1762.

BOYLE'S *Lectures*, a course of eight sermons or lectures preached annually, and originally set on foot by the Honourable Robert Boyle, whose design, as expressed in a edicil annexed to his will in 1691, was to prove the truth of the Christian religion against infidels, without descending to any controversies among Christians, and to answer new difficulties or scruples that might from time to time arise. For the support of this lecture Mr Boyle assigned the rent of his house in Crooked-lane to some learned divine within the bills of mortality, to be elected for a time not exceeding three years, by Archbishop Tension and others. But the fund proving precarious, the salary was ill paid; and to remedy this inconvenience, the archbishop procured a yearly stipend of L.50 for ever, to be paid quarterly, charged on a farm in the parish of Brill in the county of Bucks. To this appointment we are indebted for many elaborate defences both of natural and revealed religion.

BOYNE, a river of Ireland, which rises in Queen's County in the province of Leinster, and running north-east by Trim and Cavan, falls at last into the Irish Channel a little below Drogheda. It is memorable for a battle fought on its banks between James II. and King William III. in which the former was defeated.

BOYSE, Boys, or Bois, *John*, one of the translators of the Bible in the reign of James I. was son of William Bois, rector of West Stowe, near St Edmundsbury, Suffolk, and born at Nettlestead in Suffolk on the 3d of January 1560. He was taught the first rudiments of learning by his father; and his capacity was such, that at the age of five he was able, it is said, to read the Bible in Hebrew. He went afterwards to Hadley school; and at fourteen was admitted of St John's College, Cambridge, where he distinguished himself by his skill in Greek. Happening to catch the small-pox when he was a cleft fellow, he caused himself to be carried for admission in blankets, in order to preserve his seniority. He applied himself for some time to the study of medicine; but, fancying himself affected with every disease he read of, he quitted that science. He was during ten years principal Greek lecturer in his college, and read every day. He voluntarily read a Greek lecture for some years at four in the morning, in his own

chamber, which was frequented by many of the fellows. On the death of his father, he succeeded to the rectory of West Stowe. At the age of thirty-six he married the daughter of Mr Holt, rector of Buxworth, in Cambridge-shire, whom he succeeded in that living in October 1596. On his quitting the university, the college gave him L.100. But his young wife, who had been bequeathed to him with the living, which was an advowson, having proved a bad economist, and he himself being wholly addicted to his studies, he soon became so much involved in debt that he was obliged to sell his choice collection of books, consisting of almost every Greek author then extant. When a new translation of the Bible was directed to be made, Mr Bois was elected one of the Cambridge translators. He performed not only his own, but also the part assigned to another, with great reputation. He was also one of the six who had met at Stationers' Hall to revise the whole; which task they performed in nine months, having each, from the company of stationers, during that time, thirty shillings a week. He afterwards assisted Sir Henry Savile in publishing the works of St Crysostom. In 1615 Dr Laneelot Andrews, bishop of Ely, bestowed on him, unasked, the prebend in his church. He died on the 14th of January 1643, in the eighty-fourth year of his age, and left a great many manuscripts behind him, particularly a Commentary on almost all the books of the New Testament. When Bois was a young student at Cambridge, he received from the learned Dr Whitaker three rules for avoiding those distempers which usually attend a sedentary life, to which he adhered with equal constancy and success. The first was, To study always standing; the second, Never to study in a window; and the third, Never to go to bed with his feet cold.

BOYSE, *Samuel*, a man remarkable for the fineness of his genius, the lowness of his manners, and the wretchedness of his life. He was born in 1708, and received the rudiments of his education at a private school in Dublin. When he was but eighteen years old, his father, a non-conformist clergyman, sent him to the university of Glasgow, that he might finish his education there. But he had not been a year at the university, when he fell in love with the daughter of a tradesman in that city, and was imprudent enough to interrupt his education by marrying her before he had entered into his twentieth year. The natural extravagance of his temper soon exposed him to want; and as he had now the additional charge of a wife, his reduced circumstances obliged him to quit the university, and go over with his wife (who also carried a sister along with her) to Dublin, where they relied on the old clergyman for support. Young Boyse was of all men the farthest removed from the character of gentleman. He had no graces of person, and still fewer of manners or conversation. Never were three people of more libertine habits than young Boyse, his wife, and his sister-in-law; yet the two women wore such a mask of decency before the old non-conformist gentleman, that his fondness was never abated. The estate which he possessed in Yorkshire was sold to discharge his son's debts; and his means were utterly wasted, so that, when seized with his last sickness, he was entirely supported by presents from his congregation, and at length buried at their expense. We have no further account of Boyse till we find him soon after his father's death at Edinburgh. At this place his poetical genius raised him many friends, and some patrons of eminence. He published a volume of poems in 1731, to which are subjoined *The Tablature of Cebes*, and *A Letter upon Liberty*, inserted in the *Dublin Journal*, 1726, by which he obtained considerable reputation. These poems are addressed to the Countess of Eglintoun. This amiable lady was the patroness of all men of wit, and greatly distinguished Boyse

while he resided in Scotland. Upon the death of the Viscountess Stormont, Boyse wrote an elegy, which was much applauded by her ladyship's relations. This elegy he entitled *The Tears of the Muses*, as the deceased lady was a woman of the most refined taste in the sciences, and a great admirer of poetry. The Lord Stormont was so much pleased with this mark of attention paid to the memory of his lady, that he ordered a handsome present to be given to Boyse by his attorney at Edinburgh. The notice which Lady Eglintoun and the Lord Stormont took of our poet recommended him likewise to the patronage of the Duchess of Gordon, who was so solicitous to raise him above necessity, that she employed her interest in procuring the promise of a place for him. She gave him a letter, which he was next day to deliver to one of the commissioners of the customs at Edinburgh. But it happened that he was then some miles distant from the city; and that the morning on which he was to have proceeded to town with her Grace's letter of recommendation proved rainy. This slender circumstance was enough to discourage Boyse, who never looked beyond the present moment. He declined going to town on account of the rainy weather; and thus letting slip the opportunity, the place was bestowed upon another, which the commissioner declared he kept for some time vacant in expectation of seeing a person recommended by the Duchess of Gordon. Having defeated all the kind intentions of his patrons towards him, Boyse at last fell into contempt and poverty, which obliged him to quit Edinburgh. He communicated his design of going to London to the Duchess of Gordon, who, having still a high opinion of his poetical abilities, gave him a letter of recommendation to Mr Pope, and obtained another for him to Sir Peter King, the lord chancellor of England. Lord Stormont recommended him to the solicitor general his brother, and many other persons of the first fashion. Upon receiving these letters he quitted Edinburgh with great caution, despised by all, and regretted by none but his creditors. Upon his arrival in London, he went to Twickenham in order to deliver the Duchess of Gordon's letter to Mr Pope; but that gentleman not being at home, Mr Boyse never gave himself the trouble to repeat his visit. He wrote poems; but these, though possessing some intrinsic merit, were lost to the world, by being introduced with no advantage. He had so great a propensity to low company, that his acquaintance were generally of such a cast as could be of no service to him; and those in higher life he addressed by letters, not having sufficient breeding or common good manners to converse familiarly with them. Thus unfit to support himself in the world, he was exposed to a variety of distresses, from which he could invent no means of extricating himself except by writing mendicant letters. Yet this man, of so abject a spirit, was voluptuous and luxurious; he had no taste for any thing elegant, but was to the last degree expensive. Often when he had received a guinea in consequence of a supplicating letter, he would go into a tavern, order a supper to be prepared, drink of the richest wines, and spend all the money that had just been given him in charity, without having any one to participate the regale with him, and whilst his wife and child were starving at home.

About the year 1740, Boyse, reduced to the last extremity of human wretchedness, had not a shirt, a coat, nor any kind of apparel, to put on; the sheets in which he lay were carried to the pawn-broker's, and he was obliged to be confined to his bed with no other covering than a blanket. He had little support except what he got by writing letters in the most abject style; and he remained for six weeks in the situation we have described. During this time he had some employment in writ-

ing verses for the Magazines. He sat up in bed with the blanket wrapt about him, through which he had cut a hole large enough to admit his arm, and placing the paper upon his knee, scribbled in the best manner he could the verses he was obliged to write; whatever he got by these, or by begging letters, being barely sufficient for the preservation of life. And perhaps he would have remained much longer in this distressful condition, had not a compassionate gentleman, upon hearing the circumstance related, ordered his clothes to be taken out of pawn, and enabled him to appear abroad again.

About the year 1745 Boyse's wife died. He was then at Reading, and pretended much concern when he heard of her death. His business at Reading was to compile a review of the most material transactions at home and abroad during the war; and in this he has included a short account of the rebellion. Upon his return from Reading, his behaviour was more decent than it had ever been before; and hopes were entertained that a reformation, though late, might be wrought upon him. He was employed by a bookseller to translate *Fenelon on the Existence of a God*; and during the time he was occupied in this he married a second wife, a woman in low circumstances, but well enough suited to his taste. He now began to live with more regard to character, and supported a better appearance than usual; but whilst his circumstances were mending, and his irregular appetites losing their hold, his health visibly declined. While suffering from a lingering illness, he had the satisfaction to observe a poem of his, entitled *The Deity*, recommended by two writers of very opposite principles and talents, Mr Fielding the novellist, and the Reverend James Harvey, author of *The Meditations*.

Boyse's mind was often religiously disposed; he frequently talked upon this subject, and probably suffered a great deal from remorse of conscience. The early impressions of his education were never entirely obliterated; and his whole life was a continued struggle between his reason and his passions, as he was always violating the dictates of the one, while he fell under the dominion of the other. It was in consequence of this war in his mind that he wrote his poem entitled *The Recantation*. In May 1749 he died in obscure lodgings near Shoe-lane, under the influence, it is believed, of sentiments very different from those in which he had spent the greater part of his life. An old acquaintance of his endeavoured to collect money to defray the expenses of his funeral, and spare his remains the dishonour of being buried by the parish; but his efforts were vain, and the corpse of this son of the Muses was, with very little ceremony, hurried away by the parish-officers.

Never was a life spent with less grace than that of Boyse, and never were good abilities given to less purpose. His genius was not confined to poetry alone. He had a taste for painting, music, and heraldry; with the last of which he was very well acquainted. His poetical pieces, if collected, would form six moderate volumes. Many of them are scattered in *The Gentleman's Magazine*, marked with the letter Y, and the signature *Alceus*. Two volumes were published in London. An ode of his in the manner of Spenser, entitled *The Olive*, was addressed to Sir Robert Walpole, which procured him a present of ten guineas. He translated a poem from the High Dutch of Van Haren, in praise of peace, upon the conclusion of that of Aix-la-Chapelle; but the poem which procured him the greatest reputation was that upon the attributes of the Deity. He was employed by Mr Ogle to translate some of Chaucer's tales into modern English, which he executed with great spirit, and received at the rate of threepence a line for his trouble. Mr Ogle published a

complete edition of *Canterbury Tales modernized*; and Boyse's name is put to such tales as were done by him. In 1743 Boyse published, without his name, an ode on the battle of Dettingen, entitled *Albion's Triumph*.

B QUADRO, QUADRATO, or *Durale*, in *Music*, called by the French *b quarré*, from its figure $\square$. This is what we call B *natural* or *sharp*, in distinction to B *mol* or *flat*. If the flat *b* be placed before a note in the thorough bass, it intimates that its third is to be minor; and if placed with any cipher over a note in the bass, as *b* 6, or *b* 5, it denotes that the fifth or sixth thereto are to be flat. But if the quadro $\square$ be placed over any note, or with a cipher, in the thorough bass, it has the contrary effect; for thereby the note or interval thereto is raised to its natural order.

BRÁ, a city of the province of Alba, in the kingdom of Sardinia. It stands on the river Stura, and contains 11,200 inhabitants, who find employment in the cultivation of silk, and the extensive manufacture of silk goods, and in making linen and coarse cloth.

BRABANCIONES, in the writers of the middle age, a kind of Netherlands soldiery, infamous for rapine; a sort of commissioned banditti, who hired themselves to fight for any one who could pay them. The word is variously written by the historians of those days; but every variety is derived from the country of Brabant, which was the chief nursery of these troops. They are also frequently confounded with the *Routiers*, *Roturiers*, *Ruptarii*, *Ruterarii*, *Corteraux*, and others.

BRABANT. See NETHERLANDS.

BRABEUTES, or BRABEUTA, in *Antiquity*, an officer among the Greeks, who presided at the public games, and decided such disputes as occurred among the antagonists in the gymnastical exercises. The number of brabeutæ was not fixed; sometimes there was only one, but more commonly they amounted to nine or ten.

BRACCIOLINI, FRANCIS, an Italian poet, a native of Pistoja, and the friend of Pope Urban VIII. was born about the year 1566. Removing to Florence, he was admitted into the academy there, and devoted himself to literature. At Rome he entered into the service of Cardinal Maffeo Barberini, with whom he afterwards went to France. After the death of Clement VIII. he returned to his own country, and for some years prosecuted his studies in retirement. When his patron Barberini was elected pope, under the name of Urban VIII., Bracciolini repaired to Rome, where he was well received, and made secretary to the pope's brother, Cardinal Antonio. He had also the honour conferred on him of taking a surname from the arms of the Barberini family, which were bees; and he was afterwards known by the name of *Bracciolini dell'Api*. He resided in Rome during the whole of Urban's pontificate, frequenting the most illustrious academies, and listened to with general applause, but, at the same time, censured for his sordid avarice. On the death of this pontiff he returned to his native city, where he died in the year 1645. Bracciolini, was a copious writer. There is scarcely any species of poetry, epic, dramatic, pastoral, lyric, or burlesque, which he did not attempt. He is principally noted for his mock-heroic poem entitled *Scherno degli Dei*, which disputes priority of date with Tassoni's *Secchia Rapita*. In merit, indeed, its inferiority is acknowledged, yet it obtained considerable applause. Of his serious heroic poems, the most celebrated is the *Croce Racquistata*, which by some is placed next to the great works of Ariosto and Tasso, *sed magno intervallo*. He celebrated the elevation of his patron Urban VIII. in a poem of twenty-three books, which shows with what facility he could write verses. His dramatic pastoral, entitled *L'Amoroso Sdegno*, is accounted one of the best pro-

ductions of the age in which it was written; and some of his tragedies met with much applause, particularly his *Evandro*. The following is a pretty correct list of his acknowledged works: 1. *La Croce Racquistata*, poema eroico, canti xv. Paris, Rueles, 1605, 8vo; 2. *Lo Scherno degli Dei*, poema eroico-giocosso, canti xiii. Florence, 1618, 4to; 3. *L'Elezione di Papa Urbano VIII.* Rome, 1628, 4to; 4. *La Rocella espugnata*, Rome, 1630, 12mo; 5. *La Bulgheria Convertita*, poema eroico in xx. canti, Rome, 1637, 12mo; 6. *L'Evandro, l'Arpalice, la Penteseila*, tragedies, Rome, 1612, 1613, and 1615, 8vo; 7. *L'Amoroso Sdegno, favola Pastorale*, Venice, 1597; 8. *Ero e Leandro, favola Marittima con gli intermedj Apparenti*, Rome, 1630, 12mo; and *Il Monserrato*, a drama, Rome, 1629, 12mo. The titles of his other and less considerable performances may be found in Mazzuchelli.

BRACE is commonly taken for a couple or pair, and applied by huntsmen to several kinds of game, as a brace of bucks, foxes, hares, grouse, and the like.

BRACE, in writing or printing, a crooked line inclosing a passage, as in a triplet.

BRACES, in the sea-language, are ropes belonging to all the yards of a ship except the mizen, two on each yard, reeved through blocks that are fastened to pennants, seized to the yard-arms. Their use is either to square or traverse the yards. Hence to brace the yard is to bring it to either side. All braces come aftward on. Thus the main brace comes to the poop; the main-top-sail brace comes to the mizen-top, and thence to the main shrouds; the fore and fore-top-sail braces come down by the main and main-top-sail stays; and so of the rest. But the mizen-bowline serves to brace to the yard, and the cross-jack braces are brought forwards to the main-shrouds, when the ship sails close on a wind.

BRACELET, an ornament worn on the wrist, and much used among the ancients. It was made of different materials, and in different fashions, according to the age and quality of the wearer. The word is French, *bracelet*; which Menage derives further from *braceletum*, a diminutive of *bracile*, a word occurring in writers of the age of Justinian; all formed from the Latin *brachium*, an arm. It amounts to the same with what was called by the ancients *armilla*, *brachiale*, *occabus*; and in the middle ages *boga*, *bauga*, *armispatha*.

BRACHMINS, or BRACHMANS, a branch of the ancient Gymnosophists or philosophers of India. See BRAMINS.

BRACHYGRAPHY, the art of short-hand writing. See SHORT HAND.

BRACHYLOGY, (from *βραχυς*, short, and *λογος*, expression), in *Rhetoric*, the expressing of any thing in the most concise manner. This, as far as is consistent with perspicuity, is a virtue and beauty of style; but if obscurity be the consequence, which is often the case, it becomes a blemish and defect. Quintilian gives an instance of brachylogy from Sallust: *Mithridates corpore ingenti perinde armatus*; "Mithridates, as it were, armed with the hugeness of his stature."

BRACKE, or BRACHE, a bailiwick in the duchy of Oldenburg, containing three towns, with 6108 inhabitants. The chief place, of the same name, is situated on the Wiser, and is of importance from the ships, which require a greater depth of water than is to be found near Bresner, commonly remaining to discharge or receive their cargoes there. It contains only 1100 inhabitants.

BRACKENHEIM, a bailiwick in the circle of the Neckar, of the kingdom of Wirtemberg. It extends over ninety-eight square miles, and comprehends five cities, two market-towns, and twenty-nine villages, with 24,096 inhabitants. The city, which gives name to the bailiwick, is

Bract situated on the river Zaber, and contains an ancient castle, and 1684 inhabitants, who produce some good wine.

BRACKET, among carpenters and others, means a kind of wooden stay, serving to support shelves and the like.

BRACKETS, in a ship, the small knees, serving to support the galleries, and commonly carved. The timbers that support the grating in the head are also called *brackets*.

BRACKETS, in *Gunnery*, are the cheeks of the carriage of a mortar. Being made of strong planks of wood, of almost a semicircular figure, and bound round with thick iron plates, they are fixed to the beds by four bolts, which are called *bed-bolts*, and, rising up on each side of the mortar, serve to keep her at any elevation by means of some strong iron bolts, called *bracket-bolts*, which go through these cheeks or brackets.

BRACKLEY, a borough and market-town of the hundred of King's Sutton, in Northamptonshire, sixty-three miles from London. It had formerly much trade in wool, and some manufactures; but now chiefly depends on the agriculture of its vicinity. It has two churches, a handsome market-house, an endowed free school, and an hospital. The market is held on Wednesday. It returns two members to Parliament, chosen by the corporate body under the influence of the Earl of Bridgewater. The inhabitants amounted in 1801 to 1495, in 1811 to 1580, and in 1821 to 2236.

BRACTON, HENRY, Lord Chief Justice of England in the reign of Henry III., was probably a native of Devonshire. He was educated at Oxford, where he took the degree of doctor of laws, and was made one of the itinerant judges about the year 1244. Ten years after he became chief justice, and had the Earl of Derby's house in London assigned him for his town residence during the minority of that nobleman. He is said to have filled this important office with singular reputation during twenty years. The time of his death is not known; probably it occurred in the reign of Edward I. He wrote *De Legibus et Consuetudinibus Angliæ*, which is one of the most ancient and most methodical books on the laws of England. His method is copied from that of Justinian. This work was printed at London in 1569, folio; and in 1640, in 4to.

BRADFORD, or BRADFORTH, a market-town in the wapentake of Morley, of the west-riding of Yorkshire, 197 miles from London, and situated on a branch of the river Aire. It is built partly on the side of a steep hill, with some of the streets looking over the houses in the others. It has extensive manufactures of worsted stuffs, and, during the war, had several founderies for cannon, and other heavy iron articles. The market is held on Thursday. The parish church is a remarkably fine Gothic edifice, with a melodious peal of bells. The inhabitants amounted in 1801 to 6393, in 1811 to 7761, and in 1821 to 13,064. The whole parish of Bradford, comprehending twelve townships or chapelries, contained, in 1801, 28,985 inhabitants, who in 1821 had increased to 52,954.

BRADFORD, a market-town in the hundred of the same name, of the county of Wilts, 104 miles from London. It is situated on the banks of the river Avon, near to the Kennet and Avon Canal, having, by those two channels, communication with London and with Bristol. It is a great manufacturing place for broad cloths and cassimeres. The streets are narrow, crooked, and ill built; but the situation is sheltered, and it is very healthy. There are good markets on Monday and Saturday. The inhabitants amounted in 1801 to 8540, in 1811 to 9230, and in 1821 to 10,231.

BRADFORD, John, a divine, and martyr to the Reformation, was born in the early part of the reign of Henry VIII. at Manchester, in Lancashire. Being a good penman and accountant, he became secretary to Sir John

Harrington, who was several times employed by King Henry, and his successor Edward VI., as paymaster to the troops abroad. Bradford at this time was a gay man, and to support his extravagance made free with the king's money; but being at last unable to endure the reflection of his guilt, he determined to make restitution, and actually repaid the money. Quitting his employment of secretary about the year 1547, he took chambers in the Inner Temple, and for some time studied the law; but finding in himself an inclination to preach the gospel, he removed the following year to Catherine-hall, Cambridge, where he applied with uncommon assiduity to the study of divinity, and in a much shorter time than usual was admitted to the degree of master of arts, and soon after made fellow of Pembroke-hall. Bishop Ridley, who in 1550 was translated to the see of London, being charmed with Bradford's application and zeal, now sent for him to the metropolis, ordained and appointed him his chaplain. In 1553 he was also made chaplain to Edward VI.; during which time he became one of the most popular preachers in the kingdom. Such a reformer was too dangerous to be tolerated in the succeeding reign. Accordingly, Mary had hardly got possession of the crown when Bradford's persecutions began. He was first confined in the Tower for sedition, where he continued a year and a half. During this time he wrote several epistles, which were dispersed in various parts of the kingdom. He was afterwards removed to other prisons, and at last brought to trial before that court of inquisition in which Gardiner sat as chief inquisitor, where he defended his principles to the last, in contempt of their utmost power. They condemned him to the flames, and he was accordingly burnt alive in Smithfield, on the 1st of July 1555. His works are, 1. Seventy-two Letters, written to various people, whilst the author was in prison, and printed in Bishop Coverdale's collection; 2. Ten Letters, printed in Fox's Acts and Monuments; 3. Complaint of Verity, 1559, 8vo; 4. Three Examinations before the Commissioners, and his Private Talk with the Priests, with the Original of his Life, 1561, 8vo; 5. Two Notable Sermons 1574, 8vo, 1631; 6. Godly Meditations and Prayers, 1614, 24to; 7. Treatise of Repentance, 1622; with several translations and other pieces.

BRADING, a town on the eastern side of the Isle of Wight, in the county of Hampshire, ninety-nine miles from London. It has a harbour capacious but shallow, and dry at low water. It has little trade, depending chiefly on the rural inhabitants in its vicinity. A new church has been recently built here. The inhabitants amounted in 1801 to 1529, in 1811 to 1715, and in 1821 to 2023.

BRADLEY, DR JAMES, a celebrated English astronomer, the third son of William and Jane Bradley, was born at Sherborne in Dorsetshire in the year 1692. He was educated for the university at North Leach by Mr Egles and Mr Brice, who kept a boarding-school there; and from North Leach he was sent to Oxford. His friends intending him for the church, his studies were regulated with that view; and as soon as he was of sufficient age to receive holy orders, the Bishop of Hereford, who had conceived a great esteem for him, gave him the living of Bridstow, and soon after he was inducted to that of Welfrie in Pembrokeshire. But notwithstanding these advantages, from which he might have promised himself still further advancement in the church, he at length resigned his livings, that he might be wholly at liberty to pursue his favourite study of mathematics and astronomy. He was nephew to Mr Pound, a gentleman favourably known to the learned world by many excellent observations, and who would have enriched it with more, if the journals of his voyages had not been burnt at Pulo Con-

Brading
||
Bradley.

Bradley. dore, when the place was set on fire, and the English who had settled there cruelly massacred, Mr Pound himself very narrowly escaping with his life. With this gentleman Mr Bradley passed all the time he could spare from the duties of his function; and perhaps he sometimes trespassed upon them. He was then sufficiently acquainted with the mathematics to improve by Mr Pound's conversation; yet it does not appear that, in this study, he had any preceptor but his genius, or any assistant but his labour and perseverance.

It may easily be imagined that the example and conversation of Mr Pound did not render Bradley fonder of his profession than he was before. He continued, however, as yet to fulfil the duties of it, though at this time he had made such observations as laid the foundation of those discoveries which afterwards distinguished him as one of the best astronomers of his age. Although these observations were made as it were by stealth, they gained him at first the notice and then the friendship of the Lord Chancellor Macclesfield, Mr (afterwards Sir Isaac) Newton, Mr Halley, and many other members of the Royal Society, into which he was soon elected a member. About the same time the chair of Savilian professor of astronomy becoming vacant by the death of the celebrated Dr Keil, Mr Bradley was elected to succeed him on the 31st of October 1721, being then just twenty-nine years old; and he had for his colleague Mr Halley, who was professor of geometry on the same foundation. Bradley, upon his being elected to this professorship, gave up both his livings, and with great joy quitted a situation in which his duty was directly at variance with his inclination. From this time he applied himself wholly to the study of his favourite science; and in the year 1727 he published his *Theory of the Aberration of the Fixed Stars*, which is allowed to be one of the most useful and ingenious discoveries of modern astronomy. Three years after this discovery, by which Mr Bradley acquired great reputation, he was appointed lecturer in astronomy and physics, at the Museum of Oxford.

He pursued his studies with equal application and delight; and in the course of his observations, which were innumerable, he discovered that the inclination of the earth's axis upon the plane of the ecliptic was not always the same, but that it varied backwards and forwards some seconds, and that the period of these variations was nine years. This period seemed altogether unaccountable, as it could not be supposed to have any thing in common with the revolution of the earth, which is performed in one year. Mr Bradley, however, discovered the cause of this phenomenon in the Newtonian system of attraction, and published his discovery in 1737; so that in the space of about ten years he communicated to the world two of the finest discoveries in modern astronomy, which will for ever form an epoch in the history of that science.

Mr Bradley always preserved the esteem and friendship of Mr Halley, who, being worn out by age and infirmities, thought he could do nothing better for the service of astronomy than procure for Mr Bradley the place of regius professor of astronomy at Greenwich, which he had himself held for many years with great reputation. With this view he wrote many letters, which have been since found among Mr Bradley's papers, desiring his permission to apply for a grant of the reversion of it to him, and even offering to resign in his favour, if it should be thought necessary; but before Mr Halley could bring this kind project to bear, he died. Mr Bradley, however, obtained the place afterwards, by the favour and interest of Lord Macclesfield, who was subsequently president of the Royal Society. As soon as the appointment of Mr Bradley to this place became known, the university of Ox-

ford sent him a diploma creating him doctor of divinity. The appointment of astronomer at Greenwich placed Mr Bradley in his proper element, and he pursued his observations with unwearied diligence. However numerous the collection of astronomical instruments at the observatory at Greenwich, it was impossible that so accurate an observer as Dr Bradley should not desire to increase them, as well to answer those particular views, as in general to make observations with greater exactness. In the year 1748, therefore, he took the opportunity of the annual visit made by the Royal Society to the observatory, in order to examine the instruments and receive the professor's observations for the year, to represent so strongly the necessity of repairing the old instruments, and purchasing new ones, that the society thought proper to represent it to his majesty, and he gave them £1000 for that purpose. This sum was laid out under the direction of Dr Bradley, who, with the assistance of Mr Graham and Mr Bird, furnished the observatory with as complete a collection of astronomical instruments as the most skillful and diligent observer could desire. Dr Bradley, furnished with such assistance, pursued his observations with new assiduity; an incredible number of which were found after his death, and put into the hands of the Royal Society.

It has been already observed, that when Dr Bradley was elected to the professor's chair at Oxford, he gave up his two livings, which were at such a distance that he could not possibly fulfil the duties of them himself; but it happened, that after he was settled at Greenwich, the living of that parish, which is very considerable, became vacant, and was offered to him, as he was upon the spot to perform the duty, and had the claim of uncommon merit to the reward. This, however, Dr Bradley, to his honour, refused, fearing that the duties of the astronomer would too much interfere with those of the divine. His majesty, on hearing of the refusal, was so pleased with it, that he granted him a pension of £250 a year, in consideration of his great abilities and knowledge in astronomy and other branches of the mathematics, which had proved so advantageous to the commerce and navigation of Great Britain, as is particularly mentioned in the grant, dated the 15th of February 1752. Dr Bradley, about the same time, was admitted into the council of the Royal Society. In the year 1748 he was admitted a member of the Royal Academy of Sciences and Belles-lettres of Berlin, upon the death of M. Crevier, first physician to his Catholic majesty; in the year 1752, a member of the Imperial Academy at Petersburg; and in 1757, of that instituted at Bologna.

Dr Bradley was still indefatigable in his observations, and every honour he received became an incitement to obtain new distinction; but his corporeal abilities at length declined, though his intellectual suffered no abatement. In the year 1780 he became extremely weak and infirm; and towards the end of June 1762 he was attacked with a total suppression of urine, which on the 12th of July following put an end to his life, in the seventieth year of his age. He was buried at Mitchin Hampton, in Gloucestershire, in the same grave with his mother and his wife. In the year 1744 he married Susannah Peach, the daughter of a gentleman of that name in Gloucestershire, by whom he had only one daughter.

As to his character, he was remarkable for a placid gentle modesty, very uncommon in persons of an active temper and robust constitution; yet, with this untroubled equanimity of temper, he was compassionate and liberal in the highest degree. Although he was a good speaker, and possessed the rare but happy art of expressing his ideas with the utmost precision and perspicuity, yet no man

was a greater lover of silence, and he never spoke except when he thought it absolutely necessary. He did indeed think it necessary to speak when he had a fair opportunity to communicate any useful knowledge in his own way; and he encouraged those who attended his lectures to ask him questions, by the exactness with which he answered, and the care he took to adapt himself to every capacity. He was not more inclined to write than to speak, for he has published very little. He had a natural diffidence, which made him always afraid that his works would injure his character; and he therefore suppressed many, which probably were well worthy of the public attention. He first became known, as it were, in spite of himself; but the distinction which he avoided followed him. He was acquainted with many of the first persons in this kingdom, eminent for rank as well as abilities; he was honoured by men of learning in general; and there was not an astronomer of any eminence in the world with whom he had not a literary correspondence. Upon the whole, it may be said of Dr Bradley, that no man cultivated eminent talents with more success, or had a better claim to be ranked among the greatest astronomers of his age.

BRADNINCH, a town of the hundred of Hayridge, in the county of Devon, 170 miles from London, and six from Exeter. It is a poor manufacturing place, but has a corporation, and formerly returned two members to Parliament; but the inhabitants were relieved from the expense on the plea of poverty, on payment of five marks, in the reign of Henry VII. The inhabitants in 1801 amounted to 1187, in 1811 to 1321, and in 1821 to 1511.

BRADS, among artificers, a kind of nails used in building, which have no spreading heads as other nails have. They are distinguished among ironmongers by six names; as *joiners'-brads*, *flooring-brads*, *batten-brads*, *bill-brads*, *quarter-heads*, and the like. Joiners'-brads are for hard wainscot; batten-brads are for soft wainscot; bill-brads are used when a floor is laid in haste, or for shallow joists subject to warp.

BRADSHAW, HENRY, a Benedictine monk, was born at Chester about the middle of the fifteenth century. Discovering an early propensity to religion and literature, he was received while a boy into the monastery of St Werberg in that city; and having there imbibed the rudiments of education, he was afterwards sent to Gloucester College, in the suburbs of Oxford. Here for a time he studied theology with the novices of his order, and then returned to his convent at Chester, where, in the latter part of his life, he applied himself chiefly to the study of history, and wrote several books. He died in the year 1513, the fifth of Henry VIII. His poetry is not inferior to that of any of his contemporaries. His works are, 1. *De antiquitate et magnificentia Urbis Cestriæ*; 2. *Chronicon*; 3. The Life of the glorious virgin St Werberg, printed at London, 1521, 4to, in verse. The life of St Werberg forms only part of this work, which contains also a description of the kingdom of Mercia, a life of St Etheldred, a life of St Sexburg, the foundation and history of Chester, and the chronicles of some kings.

BRADSHAW, JOHN, descended of an ancient family, originally from Derbyshire, and born in 1586, officiated as president of the court, assembled at Whitehall, which tried Charles I. and condemned that unfortunate prince to lose his head on the scaffold. Being appointed speaker or president of the Parliament under Cromwell, he had a guard assigned him for the safety of his person, together with apartments in Westminster, a sum of £5000 sterling, and considerable territorial domains. But he was not destined to enjoy long the recompense of the judicial service he had rendered; for, according to the pamphlets

of the time preserved in the British Museum, he withdrew from Parliament, and died in obscurity on the 31st October 1659, a year after the death of the Protector. On the restoration of Charles II. the bodies of Bradshaw, Cromwell, and Ireton, were disinterred, suspended on the gallows at Tyburn, and then burned. But several collectors of anecdotes have asserted that Bradshaw's remains escaped this posthumous indignity; for, according to them, having caused a report of his death to be circulated, he passed into the colonies under a feigned name, in order there to enjoy the fortune he had acquired; and signaled himself in various contests in which the colonists were involved with the native Indian tribes. Some suppose that he retired to Barbadoes; others that he sought refuge in Jamaica, the conquest of Cromwell, where his epitaph is said to have been met with, written in the style of the most ardent republican. (*Gentleman's Magazine*, vol. liv. p. 834.) In *Peveril of the Peak* this story is put into the mouth of one of the characters, Major Ralph Bridgenorth, and told with admirable felicity, though, of course, with very considerable embellishment.

BRADWARDIN, THOMAS, archbishop of Canterbury, surnamed the *Profound Doctor*, was born at Hartfield in Sussex about the close of the thirteenth century. He was educated at Merton College, Oxford, where he took the degree of doctor of divinity, and acquired the reputation of a profound scholar, a skilful mathematician, and an able divine. Authors are not at one as to his first preferments. Pitt says he was professor of divinity at Oxford. They agree, however, in asserting, that from being chancellor of the diocese of London, he became a courtier and confessor to Edward III. whom he constantly attended during his war with France; assisting that victorious prince with his advice, animating the troops, and fervently praying for their success. After his return from the war he was made prebendary of Lincoln, and subsequently archbishop of Canterbury. He died at Lambeth in the year 1349, forty days after his consecration, and was buried in St Anselm's Chapel, near the south wall. His works are, 1. *De causa Dei*, printed at London, 1618, published by J. H. Savil; 2. *De Geometria speculativa*, Paris, 1495, 1512, 1530; 3. *De Arithmetica practica*, Paris, 1502, 1512; 4. *De Proportionibus*, Paris, 1495, Venice, 1505, folio; 5. *De Quadratura Circuli*, Paris, 1495, folio.

BRADY, ROBERT, a physician and historian of the seventeenth century, was born in the county of Norfolk, and admitted into Caius College, Cambridge, in 1643. He took his degree of bachelor of physic in 1653, was created doctor in that faculty in 1660, and the same year elected master of his college in pursuance of the king's mandate to that effect. In 1685 he received the appointment of keeper of the records in the Tower of London, and soon after was chosen regius professor of physic in the University of Cambridge. In 1679 he wrote a letter to Dr Sydenham on the influence of air, which was published among the works of that learned person. But his largest and most considerable performance was *An Introduction to the old English History*, and *A Complete History of England from the first entrance of the Romans unto the end of the reign of King Richard II.*, in three volumes folio, usually bound in two. In his Introduction Dr Brady maintains, first, that the representatives of the Commons in parliament, knights, citizens, and burgesses, were not introduced until the forty-ninth of Henry III.; secondly, that William Duke of Normandy made an absolute conquest of the nation; and, thirdly, that the succession to the crown of England is hereditary, descending to the nearest blood, and not elective;—principles which were afterwards adopted by Hume as the basis of his History. In the year 1681 Brady was chosen one of the represen-

Bradwardin
||
Brady.

Brady
||
Brag.

tatives for the university of Cambridge, in the parliament which met at Oxford; and again, 1685, in the parliament of James II., to whom he afterwards became physician in ordinary. But the Revolution put a stop to his public career, and he died in August 1700, immediately after the publication of his History. Dr Brady's other productions were, 1. An Answer to Mr Petyt's Book on Parliaments, London, 1681, 8vo; and, 2. An Historical Treatise of Cities and Burghs or Boroughs, *ibid.* 1690, folio, reprinted in 1704.

BRADY, *Nicholas*, an English divine, the son of Nicholas Brady, an officer of the king's army in the civil war, was born at Bandon in the county of Cork in October 1659. He continued in Ireland till he was twelve years of age; at which period he was sent over to England, entered at Westminster School, and thence in due time removed to Christ Church, Oxford, where he remained about four years. He then returned to Dublin, where his father resided, and immediately commenced bachelor of arts at Trinity College, which afterwards, on his attaining due standing, presented him with a diploma conferring the degree of doctor in divinity. His first ecclesiastical preferment was to a prebend in the Cathedral of St Barry at Cork, to which he was collated by Bishop Wettenhall. He was a zealous promoter of the Revolution, and suffered in consequence. When the troubles broke out in Ireland in 1690, Brady, by his influence, thrice prevented the burning of the town of Bandon, after as many orders had been issued for its destruction; and the same year, being deputed by the people of Bandon, he went over to England to solicit parliament for the redress of some grievances they had suffered while King James was in Ireland. What success attended this mission we know not; but Brady soon afterwards, quitting his preferments in Ireland, settled in London, where he was chosen minister of St Catherine Cree Church, and lecturer of St Michael's Wood-street. He subsequently became minister of Richmond in Surrey, and Stratford-upon-Avon in Warwickshire, and at length rector of Clapham in Surrey, which, together with his living of Richmond, he held till his death. He was also chaplain to the Duke of Ormond's troop of horse-guards, and to their majesties King William and Queen Mary. He died in May 1726, aged sixty-six. Dr Brady was accounted a man of an agreeable temper, and had the reputation of being a polite gentleman, an excellent preacher, and an indifferent poet. His name is familiar as the translator, in conjunction with Mr Tate, of a new version of the Psalms, which was licensed in 1696. He also translated Virgil's *Æneid*, published by subscription in 1726, in four vols. 8vo; and a tragedy entitled *The Rape, or the Innocent Imposture*, both very indifferent performances. His prose works consist of Sermons, three volumes of which were published by himself, and other three by his eldest son, who was a clergyman at Tooting in Surrey.

BRAEMAR, a district of Scotland, in the county of Aberdeen. See ABERDEENSHIRE.

BRAG, a game at cards, where as many may partake as the cards will supply; the eldest hand dealing three to each person at one time, and turning up the last card all round. This being done, each gamester puts down three stakes, one for each card; and the first stake is won by the best card turned up in the dealing round; beginning from the ace, king, queen, knave, and so downwards. When cards of the same value are turned up to two or more of the gamesters, the eldest hand gains; but it is to be observed that the ace of diamonds wins, to whatever hand it be turned up. The second stake is won by what is called the *brag*, which consists in one of the gamesters challenging the rest to turn up cards equal to his. But

it is to be observed that a pair of aces is the best brag, a pair of kings the next, and so on; and a pair of any sort wins the stake from the most valuable single card. In this consists the great diversion of the game; for, by the artful management of the looks, gestures, and voice, it frequently happens that a pair of fives, trois, or even deuces, outrages a much higher pair, and even some pairs royal, to the no small merriment of the company. The knave of clubs is here a principal favourite, making a pair with any other card in hand, and with any other two cards a pair royal. The third stake is won by the person who first makes up the cards in his hand one and thirty; each dignified card going for ten, and drawing from the pack, as usual in this game.

BRAGA, a city, the capital of the province Entre Douro-e-Minho, in Portugal. It is situated on an elevated plain near the river Savado, is fortified and defended by a citadel. The streets are irregular and ill paved, and the houses large, but of an antique fashion. It has an archbishop, and, besides the cathedral, six churches, seven monasteries, an archiepiscopal palace, and several hospitals. The inhabitants amount to 18,000, who are occupied in various manufactures, chiefly for the consumption of the kingdom. Long. 8. 16. W. Lat. 41. 33. N.

BRAGANZA, a city, the capital of the province of Tras os Montes, in Portugal, and the place from which the reigning family originated. It is situated on the river Fervença, one of the tributary streams of the Sabor, is surrounded with walls, and contains about 5000 inhabitants, employed chiefly in the silk trade. Long. 6. 36. W. Lat. 41. 47. N.

BRAHE, TYCHO, a celebrated astronomer, descended of an illustrious family, originally of Sweden, but settled in Denmark, was born on the 14th December 1546, at Knudstorp, in the county of Schonen. He was taught Latin when seven years old, and studied five years under private tutors. His father dying, his uncle sent him, in April 1559, to study philosophy and rhetoric at Copenhagen. The great eclipse of the sun, on the 21st of August 1560, happening at the precise time the astronomers had foretold, he began to look upon astronomy as something divine, and purchasing the Ephemerides of Stadius, gained some notion of the theory of the planets. In 1562 he was sent by his uncle to Leipsic to study law; but astronomy wholly engrossed his thoughts, and he employed all his pocket-money in purchasing books on that science. Having procured a small celestial globe, he used to wait till his tutor went to bed, in order to examine the constellations and learn their names; and when the sky was clear, he spent whole nights in viewing the stars. In 1565 a difference arising between Brahe and a Danish nobleman, they fought, and the former had part of his nose cut off, which defect he so artfully supplied with one made of gold and silver, that it was scarcely perceptible. It was about this time that he began to apply to chemistry, proposing nothing less than the discovery of the philosopher's stone. In 1571 he returned to Denmark, and was favoured by his maternal uncle Steno Belle, a lover of learning, with a convenient place at his castle of Herritzvad, near Knudstorp, for making his observations, and building a laboratory. But having married a country girl beneath his rank, this occasioned such a violent quarrel between him and his relations, that the king was obliged to interpose in order to reconcile them. In 1574, by his majesty's command, he read lectures upon the theory of comets at Copenhagen; and the year following he began his travels through Germany, and proceeded as far as Venice. He then resolved to remove his family, and settle at Basel; but Frederick II. king of Denmark being informed of his design, and unwilling to lose a man who was capable of proving such an ornament to his country,

promised to enable him to pursue his studies, to bestow upon him for life the island of Huen in the Sound, to erect an observatory and laboratory there, and to defray all the expenses necessary for carrying on his designs. Tycho Brahe readily embraced this proposal; and accordingly the first stone of the observatory was laid on the 8th of August 1576. The king also gave him a pension of two thousand crowns out of the treasury, a fee in Norway, and the canonry of Roschild, which brought him in a thousand more. James VI. of Scotland, afterwards raised to the crown of England, going to Denmark in order to marry the Princess Anne, paid a visit to our author in his retirement at Uranienburg, made him several presents, and with his own hand wrote a copy of verses in his praise; but soon after the death of King Frederick he was deprived of his pension, fee, and canonry; upon which, finding himself incapable of bearing the expenses of his observatory, he went to Copenhagen, whither he brought some of his instruments, and continued his astronomical observations in that city, till Valkendorf, chamberlain to the household of Christian IV., by the king's order, commanded him to discontinue them. He then removed his family to Rostock, and afterwards to Holstein, in order to solicit Henry Ranzou to introduce him to the emperor; and that gentleman complying with his request, he was received by the emperor at Prague with the utmost civility and respect. That prince gave him a magnificent house till he could procure one for him better fitted for astronomical observations; assigned him a pension of three thousand crowns; and promised, upon the first opportunity, a fee for him and his descendants. But he did not long enjoy his good fortune; for, on the 24th of October 1601, he died of a retention of urine, in the fifty-fifth year of his age, and was interred in a very magnificent manner in the principal church at Prague, where a noble monument was erected to his memory. His skill in astronomy is universally known, and he is famed as the inventor of a new system, which he endeavoured, though without success, to establish upon the ruins of that of Copernicus. He was very credulous with regard to judicial astrology and presages. If he met an old woman when he went out of doors, or a hare upon the road in a journey, he used to turn back immediately, persuaded that it was a bad omen. When he lived at Uranienburg, he had in his house a madman, whom he placed at his feet at table, and fed with his own hands. As he imagined that every thing spoken by mad persons presaged something, he carefully observed all that this man said; and because it sometimes proved true, he imagined it might always be depended on. A mere trifle put him in a passion; and against persons of the first rank, with whom it was his duty to keep on good terms, he openly discovered his resentment. He was very apt to rally others, but highly provoked if the same liberty was taken with himself. His principal works are, 1. *Progymnasmata Astronomica*, Uranienburg, 1588 and 1589, 2 vols. 4to; 2. *De Mundi Ætherei recentioribus phenomenis*, 1588, 4to; 3. *Epistolarum Astronomicarum libri duo*, Francfort, 1610, 4to; 4. *Calendarium Naturale Magicum*, 1582; 5. *Oratio de Disciplinis Mathematicis*, Copenhagen, 1610, 8vo. His observations were collected by his disciples, and published in 1666 in *Historiæ Cælestis xx. libris*.

It was the friendship of Tycho which formed Kepler, and directed him in the career of astronomy. Without this friendship, and without the numerous observations of Tycho, of which Kepler found himself the depositary after the death of his master, he would never have been able to discover those great laws of the system of the world which have been called Kepler's laws, and which, combined with the theory of central forces discovered by

Huygens, conducted Newton to the grandest discovery which has ever been made in the sciences, namely, that of universal gravitation.

BRAHILOW, or in Turkish IBRAHIL, a city on the northern bank of the Danube, in the province of Wallachia, in European Turkey. It has a strong citadel to defend the passage over the river, which is here divided into several branches. The trade of the place is considerable, both in corn and in preserved sturgeons. It is said to contain, besides the garrison, 12,500 inhabitants. Long. 27. 49. E. Lat. 44. 56. N.

BRAHMAPOOTRA, or BURRAMPOOTER, the largest river in India, which rises on the opposite side of the same narrow range of snow-clad mountains from which the Ganges flows. Its source has never been exactly explored, but it is supposed to be about the 32d degree of north latitude and 82d of east longitude. After winding eastward with a rapid current through Thibet, to the south of the Himalaya Mountains, where it is called Sanpoo, it washes the border of the territory of Lassa, and passes within thirty miles to the south of this capital of the Teshoo Lama. Thence it flows in a widely extended bed, and through many channels, in which is formed a multitude of islands. It receives the Painomtehiu, and many other lesser streams, before it passes Lassa, and penetrates the frontier mountains that divide Thibet from Assam. It then makes a vast sweep, and extending far to the east, until it approaches within 220 miles of Yunnan, the most western province of China, it makes a sudden curve in east longitude 96, first to the south and afterwards to the west, where it enters the province of Assam. Here it receives numerous tributary streams; and in longitude 91° 18' it divides into two great branches, which inclose an island of 120 miles in length. Continuing its course westward, it enters the province of Bengal, near to the town of Goalpara; after which it makes a circuit round the Garrow Mountains; and then altering its course to the south, it is joined by the Megna in latitude 24° 10', in the district of Dacca; and finally unites with the Ganges, about 40 miles from the sea. This great river, including its windings, has a course of about 1650 miles in length. Until 1765, the Brahmapootra was unknown in Europe as a great river, and Major Rennell, on exploring it, was surprised to find it larger than the Ganges. A small portion of the Brahmapootra flows through territories known to Europeans, and its navigation is supposed to be obstructed by cataracts on its entrance into Assam. This great river, during a course of 400 miles through Bengal, in all respects resembles the Ganges, except in one particular, namely, that during the last 60 miles before its junction with the Ganges it forms a stream which is regularly from four to five miles wide, and, but for its freshness, might be considered an arm of the sea. The junction of the two mighty streams of the Brahmapootra and the Ganges produces an immense body of fresh water, such as is only exceeded by some of the great rivers in Africa, which lie entirely within the limits of the tropical rains, or the Amazons and Orinoco in South America. The bore, which is known to be occasioned by the sudden influence of the tide into a river or narrow strait, prevails in all the passages between the islands and sands situated in the gulf formed by the confluence of the Brahmapootra and the Ganges, in a greater degree than in other rivers. (F.)

BRAHMINS, BRAMINS, BRAHMANS, or BRACHMANS, called *ब्राह्मण* by the Greek writers, the name employed to designate that body or order of priests who have always been the sole guardians, preceptors, and ministers of the Hindu religion. It is formed, by a slight modification, from that of Brahma, which is itself a derivative from Brahm, the Supreme Being, indicating the first of the

Brahilow
||
Brahmins.

Brahmins. three divine hypostases of the Hindu mythology, the creator of the world under Brahm, and the author of the sacred books called Vedas.

The Brahmins constitute the first or highest of the four *chadi* or castes into which the Hindu nation continues to be divided, as it has been from a very remote antiquity. The origin of this singular division or classification, which prevailed in ancient Egypt as it still does in the peninsula of India, and which was based upon nearly the same principles in both, is hid in the obscurity of ages. Each caste has its peculiar privileges, duties, and laws, all of which are incommunicable and unalienable. The more honourable the caste is, the more numerous are the restrictions to which its members are subjected, and the higher the prerogatives they enjoy. The fourth caste has the fewest observances to follow, but it has also the least portion of respect, and is the most limited in its rights and privileges. Every individual remains invariably in the caste in which he is born; practises its duties as prescribed in the laws relative thereto; and is precluded from ever aspiring to a higher, whatever may be his genius, his virtue, his patriotism, or his courage. The law which determines every man's position in society is immutable; and dreadful are the penalties which await him who ventures to dispense with even the most absurd rules laid down in it. To this point of honour the Hindu patiently sacrifices not only health, but life itself; degradation and infamy await him who transgresses its dictates; yet, although the code of which this constitutes part has been in force for a long series of ages, the people have never (perhaps for this very reason) thought of moderating its rigour or mitigating its oppression.

The leading castes among the Hindus are, as we have already observed, four. These are, first, the Brahmins; secondly, the Kshatriyas, or soldiers, including the princes and sovereigns, and hence sometimes called the caste of Rajahs or Rajeputras; thirdly, the Vaisyas, consisting of agriculturists and shepherds; and, fourthly, the Sudras or labourers. It is with the first of these, however, namely the Brahmins, that we are at present exclusively concerned. This is the sacred or sacerdotal caste, the members of which have maintained an authority more exalted, comprehensive, and absolute, than the priests of any other people, excepting perhaps those of ancient Egypt before the Persian invasion under Cambyzes. According to the received Brahminical tradition, that priesthood originally proceeded from the mouth of Brahma, which is the seat of wisdom, and thus, by the mere fact of their genesis, became invested with an undoubted superiority over the other castes, which sprung from inferior organs or members of the hypostatical creator; as the Kshatriyas from his heart, the Vaisyas from his belly, and the Sudras from his feet. Of the Brahmins there are seven subdivisions, which derive their origin from the seven Rishis or Penitents, the most sacred personages acknowledged by the Hindus. The Rishis are of high antiquity, being mentioned in the Vedas; and they are believed to have occasionally exercised a salutary superintendence over the gods themselves, visiting with their holy displeasure such of the divine impersonations as had been guilty of any irregularity. Their residence was fixed in the remote and elevated regions of the north; and hence the Brahmins of the north are esteemed as the noblest, from their proximity to the great fountain. The Gymnosophists, or Brahmins of antiquity, lived much more secluded than those of modern times, who mingle to a considerable extent in secular concerns. But the latter have made almost no change in their rules of abstinence, their ablutions, and multiplied ceremonies. Their great prerogative consists in being the sole depositaries and expounders of the Vedas or sacred books, four

in number, for each of which there is a separate class or branch of the Brahmins. This prerogative they guard with the most jealous care, affirming, that if a Sudra or other profane person were to attempt to read even the title of these books, his head would instantly cleave asunder; and a Brahmin bold enough to exhibit the sacred volumes to profane eyes would incur the penalty of irretrievable expulsion from his caste. Yet, with much judgment, they make an exception as to the miracle in favour of Europeans; nor has it been found expedient to enforce the law of caste against such Brahmins as may have indulged them with a perusal or even with copies of the Vedas.

The great body of the Brahmins profess to pay equal veneration to the three hypostases of the godhead, Brahma, Vishnu, and Siva. But some attach themselves exclusively to one of these impersonations; while others, admitting the divine emanation of three, exhibit only a preference in their homage, founded on certain fanciful distinctions. Thus Vishnu and Siva, though nominally co-ordinate with Brahma, have long been objects of partiality with individuals who, in virtue of such preference, are formed into sects, distinguished by the name of the hypostasis to which their chief homage is paid. The worshippers of Vishnu are denominated Namadhari, from bearing in their foreheads the mark called Nama, consisting of three perpendicular lines, crossed at the lower extremity by a horizontal one, so as to form a sort of trident; and their dress is of a deep orange colour. The devotees of Siva are denominated Lingamhari, from wearing the Lingam stuck in their hair, or attached to the arm in a tube of gold or silver. The former are notorious for intemperance, and on that account disliked by the people; the latter, for the most part, observe great moderation both in eating and drinking. The devotees of Vishnu account as sacred the monkey, the garuda, and the cobra capella; and any of their number who inadvertently kills one of these animals is obliged to expiate his supposed crime by a farcical sacrifice, in which it is pretended that a human victim is immolated and brought to life again. The mummery of this mock expiation is abundantly ridiculous. A little blood is drawn from a superficial wound in the thigh, inflicted with a knife; the victim is then supposed to be slain, and remains motionless until the farce of resuscitation is performed, when he of course comes to life again. This is performed with immense ceremony, in the presence of a great concourse of spectators, who are commonly feasted on the fine levied from the culprit; and a similar punishment is sometimes inflicted for other offences. The worshippers of Vishnu and Siva, though separated by a very thin wall of partition, are continually at variance, each sect not only striving to exalt their own divinity, but to revile that of their adversaries. The former consider the wearing of the Lingam as the most heinous of all sins; the latter, on the other hand, maintain that all who bear the Nama will, after death, be tormented in hell with a three-pronged fork, resembling that trident mark. But these sectarian notions are less prevalent among the Brahmins than the other castes. Brahmins of the Vishnu faith are only to be found in the provinces situated to the south of the Krishna, and they are regarded with contempt by their more tolerant brethren, who, in consequence, refuse to admit them to their tables or to their ceremonies, and anxiously exclude them from any public employments which happen to be at their disposal. The sects of the Nama and the Lingam are further split into subdivisions, which dispute warmly on the subjects of their differences, but are ever ready to unite when the general interests of the order are concerned.

There are four stages in the life of a Brahmin. The first commences at the age of from seven to nine, when

Brahmins. he is invested with the triple cord, which is suspended from the left shoulder, and forms the badge of his order. The youth thus initiated is denominated Brahmachari. At this stage he is occupied in learning to read and write; in committing to memory portions of the Vedas, and the efficacious forms of prayer called the Mantras; and in acquiring other knowledge. It is his duty to abstain from the use of betel, to put no ornaments in his hair, to bathe daily, and to offer the sacrifice called Homam twice a day; but subjects so young seldom observe the rules strictly. A certain proficiency, indeed, is enjoined in committing to memory the sacred books; but neither in this nor in the acquisitions which are deemed scientific is there much emulation. They are not slack, however, in learning to understand the privileges belonging to their caste, which are great and various. One of these is a right to ask alms, which they do not in the style of mendicants, but in that of confident yet not insolent claimants; another is, an exemption from taxes of all kinds, whether general or local; and a third consists in an immunity from capital, and generally from corporal punishment, however heinous the crimes they may commit, imprisonment being the only penalty to which they are liable. At this stage also they learn the different points of bodily purity which, as good Brahmins, it is necessary for them to observe through life. These are so numerous as to be excessively burdensome, and to impose on them the duty of constant and jealous vigilance. Not only are they defiled by touching a dead body, but even by attending a funeral. Child-birth and constitutional changes render females impure; and certain ablutions and forms of prayer are necessary to remove the stain. An earthen vessel, if it has been used by a profane person, or applied to certain specified purposes, becomes so polluted that it cannot be used again, and must be broken; but metallic vessels may be purified by washing. Leather and all kinds of skins, except those of the tiger and antelope, are held to be excessively impure; and the boots and gloves of Europeans are to them the most disagreeable of all articles of dress. Brahmins, in walking or sitting, must take care they do not touch a bone, a broken pot, a rag, or a leaf from which any one has eaten; in drinking, they must pour the liquid from above, without touching the vessel with their lips; and they are forbidden to touch the greater part of animals, particularly the dog, which is accounted the most polluting. The water which they drink must be carefully drawn, though never by a Sudra; and if two Brahmins draw water together, their pitchers must not come in contact, otherwise one or both must be broken. Animal food of all kinds is strictly prohibited; and among the Lingam branch of the order the prohibition is most rigidly observed, notwithstanding which this class or sect has always been remarkable for great slovenliness in their external habits. The Brahmins are also taught to entertain a horror of spiritual defilement, resulting from perversity of will, or the actual commission of sin; and although the different modes in which it is contracted are but obscurely indicated, the rules for purification by means of ablutions, penances, and ceremonies, are very fully and distinctly laid down.

The second stage of a Brahmin's life is the state of Grihastha, which takes place when he is married, and has children; both these circumstances being essential to its constitution. Marriage is an important object to a Brahmin, inasmuch as it insures him consideration and respectability in society. Hence, when he becomes a widower, he falls from his station, and is consequently under a moral necessity of re-entering the married state. But the case is quite different with widowed females, who are not permitted to marry a second time. The Sunnyassis, how-

ever, probably in imitation of the ancient Rishis, lead lives of celibacy; and the acting priests, called Gurus, also live in a state of single blessedness, although their morality in this particular is sufficiently relaxed. When a Brahmin, therefore, takes his wife home and has children by her, he enters his second state, or that of Grihastha. His daily duties and ceremonies now become more multiplied and imperative; and every act of his life must be performed according to certain rules, some of them sufficiently repugnant to European notions of propriety. These observances, which from their number and incessant recurrence would seem burdensome and oppressive, become so habitual from daily practice that they are not felt as galling or irksome. On the contrary, the Brahmins perform all of them cheerfully, and no innovation is ever proposed. Some Hindu writers, indeed, have turned them into ridicule, and joked at the expense of a ritual which they nevertheless continued in practice to observe. But, from all that we can learn, the authors who have indulged in this license were never Brahmins, but generally Sudras, or men of the lowest caste, who had been contaminated by association with Europeans. Vemana, Agastya, Patanapulai, and Tiruvaluven, a Pariah, the principal scoffers, answer to this description; they are all modern, and either Sudras or men of no caste whatever. If any ancient authors wrote in the same strain, their names and their works have equally perished. At the same time, although speculative scepticism be but rarely avowed, practical transgressions are secretly indulged in, especially in large towns, where concealment is easy and temptation strong.

Nor is this all. Many Brahmins habitually engage in transactions and employments which appear altogether at variance with their professions and pretensions. They are commonly the political functionaries or agents of the native princes, and of the Mahomedan governments, which find it convenient to employ these hereditary ministers of religion, from the influence they possess over the minds of the people. Some of them, particularly in Gujerat, embark in commercial speculations, and become merchants, bankers, or general agents. Others, again, carry messages between distant places, or are sent as vakeels on difficult and important missions; the veneration in which they are universally held securing them from molestation in the discharge of such tasks. A third class act as coolies or porters, in which character they alone are exempt from the demands of the tax-gatherer. Many of them enter the Company's native army, and often rise to the rank of subadar. In a word, they are as much alive to selfish considerations and interests as any other tribe or caste, and ready, on all occasions, to avail themselves to the utmost of the privileges and immunities belonging to their order. Their rapacity, in fact, is only exceeded by their cunning; nor is there to be found in any country a set of more artful impostors. The Hindus are all expert in disguising the truth; but the Brahmins, in this respect, possess an unquestioned superiority. They are supple, insinuating, false; acute in discerning, and skilful in taking advantage of the foibles of others; naturally vindictive and proud, yet, from habit and cunning, patient and submissive; evincing on all occasions the most perfect self-command, and ever ready to profit by the indiscretion, weakness, or simplicity of those with whom they may have to do. One of their prime resources is flattery, which they lavish with unbounded profusion on any person whom they wish to cozen or hope to conciliate; experience having convinced them, that even those who pretend to repudiate their adulation nevertheless lay a portion, at least, of the grateful unction to their souls. In matters of religious opinion they are upon the whole tolerant; they almost never anathematize Moslems, Christians, and others of different creeds; nor

Brahmins. do they seem to be at all actuated by the fierce spirit of proselytism and persecution. But this forbearance may perhaps be the consequence, not of any virtue in the Brahmins, but of the low estimation in which they hold the objects of their own worship; for, undoubtedly, they sometimes treat the latter with an indifference bordering on contempt, and in their adorations are influenced by their secular interests rather than by the spirit of devotion, flattering those divinities whose functions they connect with their worldly affairs, and giving themselves no concern about the others.

The distance at which they keep themselves from Europeans, and the unwillingness they evince to admit the latter to their temples or their ceremonies, may seem inconsistent with what has just been advanced. But their conduct in this respect arises solely from the uncleanness which they attach to our habits; and were Europeans to conform a little more to their manners and practical prejudices, there can be no doubt that the consequence would be a closer intimacy and unbounded toleration. This was fully experienced by the Abbé Dubois, who having carefully studied the manners of the Hindus, and uniformly treated their habits with respect and tenderness, was often invited by the Brahmins of his acquaintance to enter their temples and join in their ceremonies. Among the sacerdotal order of India it is a prevalent sentiment that different religions are formed for different nations, and that each serves every necessary purpose to the souls of its believers and professors. But in their attachment to their civil institutions the Brahmins are less liberal and conciliating, considering every thing different from these or opposed to them as the product of absolute barbarism. The Moors they hate for their arrogance, and despise for their ignorance of some branches of mathematical science known to themselves, such as those connected with the construction and explanation of the almanack. In the European masters of India, they admire their humanity in war, the moderation and impartiality of their government, the general uprightness of their conduct in the intercourse of life, and the benevolent generosity of their dispositions; but these favourable impressions are apt to be forgotten when they think of the grossness and hatefulness of their prevailing habits, such as eating animal food, and admitting the detested Pariahs into their domestic service. Such things are pre-eminently odious to Hindus, and both, we think, might have easily been avoided. No extraordinary effort of self-denial would have been necessary to enable Europeans to abstain from the use of beef, which is an insipid food in India; and, with regard to the Pariahs, although it would undoubtedly be wrong to countenance the Brahmins in their barbarous treatment of the inferior castes, and of those who are considered as of no caste, yet regulations might have been adopted by which men of high caste would have been spared the gross insults they are at present exposed to, and every humane purpose at the same time attained.

The third state of a Brahmin is denominated Vanaprastha, or that of inhabitants of the desert. The order of Brahminical anchorites prevailed at a former period, but it is now scarcely to be found, and appears to be very nearly, if not altogether, extinct. The members of it were usually styled Rishis, or Penitents. They were honoured by kings, and respected by the gods, who, on account of the odour of their sanctity, seem to have considered them as in some degree their superiors. They practised self-denial according to certain rigid rules, and performed peculiar sacrifices and religious observances. Their pious acts and intentions were often thwarted by giants, and even by gods, who seem to have had no relish

for the severe discipline of the order; but in the end the Brahmin Penitents always prevailed, and sometimes took the gods roundly to task for their misdeeds. They were the depositaries of the more sublime doctrines of theology, and practised magical incantations.

The fourth state of a Brahmin is called Sunnyassi, and is reckoned so pre-eminently holy that, in a single generation, it imparts a greater stock of merit than could be accumulated during ten thousand in any other sphere of life. As a natural consequence, when a Sunnyassi dies, he is believed to pass at once into the region of Brahma or Vishnu, exempt from the penalty of being re-born on earth, or animating in succession different bodies, conformably to the metempsychosis of the Hindu mythology. In preparation for this state, a Brahmin performs all the rites of the Vanaprastha, and in addition renounces every worldly connection, takes up the profession of mendicity, and lives solely by alms. He must previously, however, have devoted several years to the married and paternal state, and thus discharged the debt which he owed to his forefathers. When duly qualified and disposed for entering the holy state of Sunnyassi, he is installed as such with many Mantras and other ceremonies. His duties now increase in number and severity. He must every morning rub his whole body over with ashes, restrict himself to one meal a day, give up the use of betel, avoid looking at women, shave his beard and head every month, and wear wooden clogs on his feet; in travelling, he must carry his seven-knotted bamboo staff in the one hand, his gourd in the other, and the antelope skin under his arm, in other words, display the three badges of his order; and he must erect a hermitage on the bank of a river or a lake. Contemplation, and a supposed communion with the Deity, amounting in its highest form to a participation of the divine essence, constitute the ulterior duties of this class of devotees. Need we wonder that, being thus privileged to indulge in all manner of extravagances, and to give full swing to an excited imagination, their practices should be in the highest degree preposterous, and their fantasies equally wild and ridiculous? In fact, the tricks which they perform are endless. The highest act of merit among them is "to subdue all sensation, and retain the breath with such determined perseverance, that the soul, quitting the body, bursts through the crown of the head, and flies to re-unite itself with the Great Being, or Para-Brahma." Accordingly, one of their fantastical exercises consists in suppressing their breath as long as possible, till they almost swoon away, and bring on most profuse perspiration. Another consists in putting themselves in the most irksome and ridiculous postures, and remaining so for a considerable length of time, indeed till exhaustion or decrepitude ensue. To stand on one leg till it swells and ulcerates; to stand on the head till the brain becomes disordered, and delirium ensues; to keep one arm extended aloft in the air till the muscles become rigid, and the power of withdrawing it is lost for ever; such are among the most approved practices of the Sunnyassis. But still the most extravagant and fatal efforts of these extraordinary devotees seem to have been confined to former times. We may add, that the Sunnyassis are not, like the Vanaprasthas, burned when they die, but interred. This is the case with the Lingamhari, or worshippers of Siva; but a Sunnyassi, even although he had, during life, attached himself to the worship of Vishnu, is interred when dead, and the ceremony is both pompous and expensive.

From the classes of Vanaprastha and Sunnyassi have sprung numerous sects of fanatics, such as the Djogis, who seek to propitiate the Deity by mutilating their bodies, or braving the force of fire and the inclemency of the seasons; the Panduris, who carry about small figures of the

most indecent description, as provocatives to devotion; and the Vairagis, who form a kind of mixed order of monks and nuns, consecrated to the god Krishna and his mistress Rada, whose history they celebrate in songs, accompanied with the tinkling of cymbals. It is also said that some of the Brahmins, under the denominations of Pashandias and Sarwaginas, maintain libertine and atheistical opinions; and it is probable that the number of those who secretly cherish such sentiments is much greater than that of the class or sect which openly avows them. Superstition, when sustained neither by fanaticism nor enthusiasm, is the natural parent of that infidelity by which it is ultimately undermined.

From what has been stated in the course of this exposition, some idea may be formed of the general character of the sacerdotal caste in India. According to the best authorities on the subject, the number of Brahmins who are respectable for their knowledge and their virtue is exceedingly small; whilst the great majority of these hereditary priests is completely devoted to ambition, intrigue, and voluptuousness, and disgraced by an avarice, a meanness, and a cruelty, which inspire strangers with no sentiments towards them but those of contempt and aversion. The charity which they place so high in the scale of duties and virtues, being equally confined by the law of caste, and the operation of that intense selfishness by which the whole tribe is characterised, has no human beings except Brahmins for its objects. Towards the other castes they cherish no feeling of humanity, and cautiously abstain from any reciprocation of kindness; they exact every thing in virtue of their rank, functions, and pretended sanctity, but take care to give nothing in return. Instead of the retired and contemplative life which appears to have been observed by the order in ancient times, and to which they still profess to devote themselves, they are immersed, as we have already seen, in pursuits the most foreign to and inconsistent with the duties and character of a priesthood; and, accordingly, they have declined alike in dignity, in reputation, and in knowledge. Yet their influence as a body still remains unshaken; neither the violence of conquest, nor the shock of revolution, nor even the power of time itself, appears to have sensibly impaired their dominion over the minds of the other castes. The institutions to which they owe their ascendancy, and by which it will in all probability be maintained for ages yet to come, have struck their roots so deeply, and become so intimately identified with the genius, character, habits, sentiments, feelings, prejudices, and daily usages of the people, as to resist the operation of all those natural, moral, and political causes which bring about changes in other countries, and, amidst all the evils incident to convulsions and innovations, ultimately contribute to the general advancement. In India, society appears to have been arrested at a particular stage of its natural progress, and re-constituted so as never to exceed the limit which it had attained before its onward tendencies were paralyzed, and the characteristic of immutability firmly established. Hence it may be considered as forming what the schoolmen would probably have denominated a political *nunc stans*; as standing to other communities of men in nearly the same relation that eternity bears to time: and hence, also, the permanency of an influence which the possessors of it take no means to extend or improve, in the conviction that it can never be materially abridged.

The authenticity as well as the antiquity of the sacred books of the Brahmins has been alternately asserted and denied, with equal zeal and pertinacity. Without entering into this question, however, it may be satisfactory to show of what materials these writings really consist; for if they are utterly worthless and contempt-

ible in themselves, as indeed seems to be the case, it matters but little to inquire whether they be genuine or spurious, of ancient or comparatively modern origin. And, on this subject, we prefer citing authorities to delivering any opinion of our own. "The sacred writings of the Brahmins," says an able writer in the *Quarterly Review*, "have been long mentioned with those phrases of solemn wonder, which would still have misled the public, if the translations and extracts of them which have successively appeared had not discovered their puerility and imposture. It is therefore important that the Sanscrit books, which have been held up as so sacred and so ancient, and which some of our learned Orientalists obviously prefer to the Jewish historian, should be given to Europe in the languages familiar to every one; that we may not be blinded by the erroneous admiration of credulous and misjudging enthusiasts, but be enabled to criticise fairly, and judge impartially for ourselves." (Vol. ii. p. 68.) Mr Mill, speaking of Sanscrit poetry generally, pronounces a judgment still stronger than that delivered by the Reviewer. "These fictions," says he, "are not only more extravagant and unnatural, less correspondent with the physical and moral laws of the universe, but are less ingenious, more monstrous, and have less of any thing that can engage the affection, awaken sympathy, or excite admiration, reverence, or terror, than the poems of any other, even the rudest people, with whom our knowledge of the globe has yet brought us acquainted. They are excessively prolix and insipid. They are often, through long passages, trifling and childish to a degree which those acquainted with only European poetry can hardly conceive. Of the style in which they are composed, it is far from too much to say, that all the vices which characterise the style of rude nations, and particularly those of Asia, they exhibit in perfection. Inflation, metaphors perpetual, and those the most violent and strained, often the most unnatural and ridiculous, obscurity, tautology, repetition, verbosity, confusion, incoherence, distinguish the Mahabharat and Ramayan." (*History of British India*, vol. ii. p. 46.) The following passage, extracted from a most masterly article which appeared in the *Edinburgh Review* (vol. xv. p. 175), is, if possible, still more to our present purpose. "It may be said," the Reviewer observes, "that in a country of which the actual condition is so imperfectly known, investigation should first be directed to the existing state of society, which admits of being accurately ascertained, and may lead to practical conclusions highly beneficial to the community, before we attempt to explore the obscure paths of remote antiquity, by the feeble lights afforded by a few mutilated or suspicious documents. The Indian nations, it may be contended, have no claim to any extraordinary attention, either from the philosopher or the historian: their boasted civilization has rather been asserted than proved; neither their literature nor their arts indicate any considerable progress in the pursuits which refine and adorn mankind; and some of their customs betray a ferocity scarcely to be found amongst the most savage nations. But, even admitting that it would be desirable to trace the remote revolutions which this people have undergone, the little probability of attaining any deductions which may be relied on with confidence ought to induce us to relinquish so hopeless a task. The Puranas appear to be extravagant romances, which, however amusing as poetical compositions, can furnish no additions to authentic history, whatever portion of it they may be supposed incidentally to contain. When we find gods and heroes mingling in doubtful fight; events natural and supernatural succeeding each other indifferently; a fact probably historical, followed by another evidently allegorical; the only rational conclusion is to consider the whole of these poems

Brahmins. as works of imagination, and to appreciate their merits by the rules applicable to similar compositions amongst other nations. But if such be the judgment we must pass on the Puranas, the Hindu compositions of a later date are not better entitled to attention, unless with respect to poetical excellence: and it probably may be affirmed that the Hindus cannot produce a single historical composition; whilst the Mahomedans of the same country have amply, and even ably, illustrated all the events subsequent to their entrance into Hindustan."

Such are the judgments which have been pronounced by some of the ablest writers of our time, respecting the sacred writings of the Brahmins, and the impossibility of deducing any sound or rational conclusions from these fanciful and extravagant compositions. But, on the other hand, it has been contended, with much plausibility and some degree of justice, that an indiscriminate accumulation of facts is no object with the philosopher, and only a subordinate one with the historian; that in proportion to the peculiarity and reputed antiquity of the religious and civil institutions subsisting amongst any people, it is natural to feel curiosity as to their origin; that the minute peculiarities which discriminate the nations of Europe scarcely produce any sensible modification of character, or exhibit to our observation any beings whose manner of thinking and acting is materially different from our own; that, in order accurately to appreciate the efficacy of religious dogmas and civil institutions in modifying the character of a people, our observation should be particularly directed to those nations which, in these respects, differ most widely from ourselves; that to this source may be traced much of the instruction as well as amusement derived from a perusal of the classic compositions of antiquity; that, from the same cause, the manners of savage tribes have attracted and deserved the attention of the philosopher, although these are in general extremely uniform, and little modified by any other circumstance than the greater or less facility of obtaining food; that, nevertheless, it is not amidst a people in such a stage of society that the influence of moral impressions can be accurately ascertained; that a nation must have advanced some steps in civilization, must have cultivated the arts, and been tinged with science, before it becomes susceptible of that indelible stamp which defies the efforts of time; and that if, upon these grounds, the peculiarities of the Hindu institutions, opinions, and manners, deservedly render them the object of philosophic research, the gradations by which such a state of society was attained must be highly interesting, and can only be discovered through the medium of such literary monuments as are still extant among them. Their sacred books, therefore, must ever possess a value, independent of all that may be said of their contents, or objected to the antiquity claimed for them. They embody evidence of the existence of peculiar modes of thinking, and forms of belief, as well as of the effects produced by peculiar institutions, civil and religious; and, as such, they can never cease to be regarded with interest, both by the philosopher and the historian.

Of ancient Brahminical science the principal remains are their astronomical tables and trigonometrical methods, both of which have given occasion to frequent and learned discussion in this and other countries of Europe. At present, however, we can only refer the reader to the works of Bailly, Playfair, and Delambre, in which he will find the subject treated with equal learning, ingenuity, and scientific precision, though in opposite views, and with very different aims. As to the science of the modern Brahmins, it seems, as we have already remarked, to be confined to the construction and explanation of the almanack; and even this scanty amount of knowledge is the

portion of but few of their number. They have indeed fallen from the proud eminence which was occupied by their order when the sages of Greece travelled into India to learn wisdom in that great storehouse of knowledge, and afterwards to carry it back to their own country, in order to plant there the first seeds of civilization. But there is one species of learning for which they have always evinced a singular aptitude and inclination; we mean metaphysical speculation, which possesses many attractions to men remarkable alike for the indolence of their habits and the extreme subtilty of their genius. In this department of research they had accordingly explored the whole cycle of systems, distinctions, classifications, refinements, and doubts, long before the western world had emerged from primeval barbarism; and in India the human mind had exhausted itself in endeavouring to detect the laws which regulate its own operations, when the philosophers of Greece were only beginning to enter within the precincts of metaphysical inquiry. Nor is it by any means certain that the latter are entitled to the credit they have received on the score of originality; that they did not borrow rather than invent; and that to the Gymnosophists of India belongs the honour of framing those systems which have been, perhaps too hastily, attributed to their disciples. It is even doubtful whether Aristotle himself did not derive both the materials and the arrangement of his system of logic from the same source. In a Mahomedan history, quoted by Sir William Jones, it is expressly mentioned that Callisthenes, having procured a regular treatise on logic, somewhere in the Punjab, transmitted it to Aristotle; and although this does not certainly prove that the Greek philosopher adopted as his own the system which had been sent him by his pupil, it at least warrants a conjecture that he might have done so; more especially as the syllogistic method was undoubtedly known in India long before his time, and as the fact must have been discovered by the numerous learned and accomplished men who accompanied Alexander's expedition. But be this as it may, one thing is pretty certain, that there is scarcely a hypothesis advanced by metaphysicians in ancient or modern times, which may not be found in some of the Brahminical writings. In these we meet with materialism, atomism, pantheism, Pyrrhonism, idealism, and every other fanciful variety of opinion which has yet been imagined or promulgated respecting God, the world, and the human soul. The Brahmins could boast of their Spinozas, their Berkeleys, and their Humes, long before Alexander dreamt of passing the Indus, and erecting a throne on the banks of the sacred stream. That Pythagoras borrowed from them the greater part of his mystical philosophy, his notions respecting the properties of numbers as expressive of physical laws, his doctrine of the transmigration of souls, and the arguments by which he inculcated the unlawfulness of eating animal food, seems to admit of no doubt whatever; for all these things are of the very essence of Brahminism, and are to this hour taught and enforced by the sacred order in India.

Egypt and India, as we have already observed, are the only two countries in which the institution of castes has obtained in its most rigid form. This identity is of itself sufficiently remarkable; but there are other points of resemblance which we think even more striking. In ancient Egypt the cow was a principal object of religious adoration, and as such accounted peculiarly sacred; and we need scarcely add that, in India, the same superstition has prevailed to an equal, if not greater extent, ever since the introduction of the Brahminical religion. The Egyptians worshipped Apis or the sacred bull, and the figure of this animal forms part of every hieroglyphical inscription, either as a symbol or a phonetical character. In some of their festivals the Brahmins exhibit the same species of idolatry,

Brahm with rites and observances exactly similar to those anciently practised in the country of the Pharaohs; and, judging by the inscriptions on their monuments, this type of animal worship must have prevailed in India from the earliest times. The astronomical character of the Egyptian mythology is well known to those who have studied its details; it seems to have been merely a reflex image of Tsabaism, or the worship of the host of heaven, the form of idolatry which first obtained among "the world's gray fathers" in the regions of the East. But the same thing, in the same sense, may be predicated of the Hindu mythology, in its purest form, before it was overlaid with the monstrous and fantastical inventions of a juggling priesthood. What inference, then, ought we to deduce from these and numerous other facts of a similar description which might be mentioned? Did Egypt derive its superstitions from India, or has India borrowed its mythology from Egypt, or have both drawn from a common source? Which is the original and which the copy, or are both merely copies from an original no longer extant? These are questions to which, in the present state of our knowledge, it is difficult, if not impossible, to give a satisfactory answer; although speculation has been busy on the subject, some contending in favour of Egypt, others in favour of India, and others, again, seeking a common source in that intermediate region, which formed as it were the cradle of the human race. We have no intention whatever to enter into these disputations, or to hazard conjectures respecting a subject in regard to which no safe or certain data have as yet been obtained. We may nevertheless be permitted to observe, that the question is chiefly one of pure chronology; that on this subject much still remains to be done before we can arrive at any well-founded conclusion respecting the comparative antiquity of these ancient nations; but that, in as far as we are at present able to see our way, the balance of probability appears to incline pretty decidedly in favour of the country of the Pharaohs.

BRAHOOICK MOUNTAINS, a chain of mountains so called by Colonel Pottinger, from the Brahooes, who inhabit them. They run along the eastern frontier of Persia, and extend 280 miles in length from south-east to north-east, and about 200 miles in their utmost breadth, under latitude 28. N. This range of mountains springs abruptly to a conspicuous height and grandeur, out of the sea at Cape Mowaree, in longitude 66° 58' E. latitude 25° N., whence it assumes a north-easterly direction for ninety miles. It there projects a ridge east by north, the base of which is washed by the river Indus, at the foot of Sehwan. From the separation of this chain, in latitude 25° 45', to that of 30°, the primitive body runs due north, now marking the western limits of Sindé, Kutch Gundava, and a part of Sewestan, as it formerly did that of Hindustan. It thence once more regains its original inclination to the north-east, and decreases in elevation so rapidly, that in the course of forty miles it sinks down to a level, and becomes incorporated with the hills inhabited by the Kaukers and by other Afghan tribes. To the westward the Brahooick Mountains are far more complicated. At their

emergence from the ocean their breadth does not exceed thirty miles from the one base to the other; but from the latitude of twenty-five and a half degrees, they progressively sweep round to north, north-north-west, north-west, and west-north-west, expanding over several degrees of longitude, and sending forth many collateral chains. The main range stretches away towards the north, to the twenty-eighth degree of north latitude, where it meets the sandy desert about the sixty-fourth degree of east longitude; it afterwards sinks, like the eastern front, to an equality with the Afghan hills, among which it is lost. This chain of mountains reaches in some parts to a great altitude, and has many peaks covered with snow. (Pottinger's *Travels in Beloochistan and Sindé*.) (F.)

BRAINTREE, a market-town in the hundred of Hinkford and county of Essex, 40 miles from London. It was the first seat of the baize manufacture introduced into England by the Flemings in the reign of Elizabeth, but that trade is nearly altogether removed to the north of England. It is situated in a very beautiful and fertile district, and a silk manufactory has recently been established. There is a market on Wednesdays. The inhabitants amounted in 1801 to 2821, in 1811 to 2298, and in 1821 to 2983.

BRAKEL, a circle in the Prussian government of Minden and province of Westphalia. It extends over 134 square miles, or 85,760 acres, and contains five cities, thirty villages, and fifteen hamlets, and a population of 21,201 persons. It is well cultivated and fertile. The dense population finds employment in making the coarse linen well known by the name of paderborns. The chief town has the same name as the circle, is situated on the river Brucht, and contains 380 houses, with 2550 inhabitants.

BRAMA, or BRUMA, a pagan deity of the East Indies. See BRAHMINS.

BRAMAH, JOSEPH, a practical engineer and machinist, was born at Stainborough, in Yorkshire, on the 13th of April 1749. His father rented a farm on the estate of Lord Strafford; and, being the eldest of five children, he was intended for the same employment. He exhibited at a very early age an unusual talent for the mechanical arts, and succeeded, when he was quite a boy, in making two violoncellos, which were found to be very tolerable instruments; as well as in cutting a single block of wood into a violin, chiefly by means of tools which were forged for him by a neighbouring smith, whom, at a subsequent period of his life, he induced to assist him in London as one of his principal workmen. Notwithstanding the ingenuity which he had thus displayed, his destination in life might have precluded its further cultivation, had he not, fortunately for himself and for the public, been incapacitated, when he was about sixteen, by an accidental lameness in his ankle, for the pursuit of agricultural labour. He was then apprenticed to a carpenter and joiner, who seems, however, to have contributed but little towards his improvement in mechanical knowledge.

When the term of his engagement had expired, he obtained employment for some time in the workshop of a cabinet-maker in London, and soon after established himself as a principal in that business. Another accidental confinement left his mind at liberty for a time to occupy itself with reflection and invention; and he employed his involuntary leisure in the improvement of some of the most humble, but not the least useful, of domestic conveniences. He obtained a patent for his inventions, and established a manufacture of these and other similar articles in Denmark Street, Soho, where he continued to simplify and improve the arrangement of the pumps and pipes subservient to his principal purpose. He procured in 1783 a patent for a water-cock, intended to allow the

Braintree
||
Bramah.

Bramah. fluid a more uninterrupted passage through it than was practicable in the ordinary construction. He afterwards removed to Piccadilly, and established the various branches of his manufactory in some extensive premises at Pimlico.

In 1784 Mr Bramah took out a patent for his improvement in locks, which certainly appear to be of very material importance. Their peculiar character depends on the arrangement of a number of levers or sliders, in such a manner as to preserve, when at rest, a uniform situation, and to be only pressed down by the key to certain unequal depths, which nothing but the key can ascertain; the levers not having any stop to retain them in their required situation, except that which forms a part of the key. The construction is more particularly detailed in the specification of the patent (*Repertory of Arts*, vol. v. p. 217), as well as in the inventor's *Dissertation on Locks*, 8vo; and some additional modifications, allowing the key to be varied at pleasure, are described in a patent, dated in 1798. It is not easy to say why the application for an act of parliament to prolong the privilege proved unsuccessful, unless it was supposed that the inventor had been already sufficiently remunerated for the share of ingenuity which his contrivance exhibited; but the report, that one of these locks had been readily opened, before a committee of the House of Commons, by means of a common quill, was a gross misrepresentation of the fact; the quill having in reality been previously cut into the required shape from the true key. The experiment, in fact, only served to show the perfection of the workmanship, so little force being required to overcome the resistance when properly applied.

For different modifications of pumps and fire-engines Mr Bramah took out three successive patents, the two last being dated in 1790 and 1798. (*Repertory*, vols. ii. iii.) His "rotative principle" consists in making the part which acts immediately on the water in the form of a slider, sweeping round a cylindrical cavity, and kept in its place by means of an eccentric groove; a construction which was very possibly suggested by his own inventive mind, but which had been before described, in a form nearly similar, by Ramelli, Cavalleri, Amontons, Prince Rupert, and Dr Hooke. The third patent related chiefly to the attachment of a considerable reservoir of water to the fire-engine in a cylindrical form, and to the furnishing of it with wheels of its own, of a proper size and strength to allow it to be conveniently worked.

There was somewhat more of originality in the idea of applying practically, to the purpose of a press, the well-known principle of the hydrostatic paradox, by which, as by a lever with arms capable of infinite variation, the smallest imaginable weight is made capable of holding in equilibrium a force incomparably greater. Mr Bramah's patent for the invention is dated in the year 1796 (*Repertory*, vol. vi. p. 289), and it has been one of the most successful of his numerous speculations. He added to it, in a subsequent patent, the contrivance of a "retainer," for keeping goods in a constant state of pressure for an unlimited time after their removal from the press. The apparatus has certainly a considerable advantage in the great steadiness with which the force can be applied, in the facility with which it can be regulated, and the convenience with which it can be continued without alteration; and it has been extensively applied, both on a small and on a large scale, for copying writings, for pressing gunpowder, for proving cables and chains, for raising weights of various kinds, and for drawing piles, and pulling up trees by the roots.

A simple but a very convenient arrangement of little pumps and pipes has been very generally employed in public-houses under the name of the beer-machine: for this Mr Bramah took out a patent in 1797, describing it

as part of an apparatus for retaining, drawing, and clarifying liquors (*Repertory*, vol. ix. p. 361). He prefaces his specification with some general observations on the right of an inventor to a property, both in the objects which he selects for his improvements, and in the means which he employs for the attainment of them; and demands of the public justice an ample security for both these rights, grounding this claim on his resolution to make a clear and unreserved disclosure of all his inventions. Besides the method of pumping up the liquors from the various casks through flexible pipes, without the necessity of entering the cellar, he describes a mode of converting every cask into a forcing pump, excluding the air, and raising the liquor to any part of the house, by a load on its head, which is to be converted into a piston. He mentions also a filtering machine, a vent peg, a method of making pipes, and a new form of stop-cocks.

In 1801 he obtained a patent for some improvements in the construction of steam-engines, particularly relating to the boilers; and in 1802, one for a very elaborate and accurate machine for producing smooth and parallel surfaces on wood and other materials. The tools of different kinds employed in this machine, such as gouges, spokeshaves, and planes, are carried with a considerable velocity by a rotatory motion, and come successively in contact with the wood, which is placed on a movable carriage gradually advancing. The centre or gudgeon of the axis or shaft, instead of a common step, is supported by a barrel of oil, to which it is fitted by a collar; and this arrangement not only diminishes the friction very considerably, but allows the height of the shaft also to be very easily and accurately regulated by means of a small forcing pump. The inventor thinks this liquid support likely to be as permanent as it is advantageous; but it may be apprehended, that the constant friction of such a collar would cause it to require frequent repairs, in order to prevent the escape of the oil so powerfully compressed. The machine has been erected on a large scale in the arsenal at Woolwich, and is employed with perfect success. The specification includes the description of a mode of turning spherical surfaces, either convex or concave, by the simple contrivance of a tool, movable on an axis precisely perpendicular to that of the lathe; and of cutting out concentric shells, by fixing, in the same manner, a curved tool, nearly of the same form as that which is employed by the common turners for making wooden bowls.

An improvement in the processes for making paper, with the assistance of new machinery, in large sheets, was secured to the inventor by a patent in 1805 (*Repertory*, second series, vol. viii. p. 1). The description is accompanied by that of a mode of drying the paper on sliding frames, hung on lines like sashes, and of keeping it in a state of compression by retainers adapted to the hydrostatic press; but Mr Bramah had not leisure to introduce these arrangements into actual practice, although he had been at a considerable expense in preparing the apparatus.

His next invention was, however, very effectually carried into execution in a particular department, notwithstanding its unpromising appearance, as generally stated in the specification of the patent, which he obtained in 1806 (*Repertory*, second series, vol. x. p. 329). He proposes to facilitate the process of printing by means of a roller, composed of a number of circular plates, closely fitted together, and turning on the same axis, each bearing twenty-six letters, with figures, spaces, and various marks, either engraved or projecting, and capable of being shifted at pleasure, so as to express any single line by a proper combination of the plates. This is described as a substitute for common printing, copperplate engraving,

and calico printing; and the ink is intended to be supplied by a trough fixed above, and in contact with the cylinder. Now it is obvious that such a machine would be insufferably tedious and inconvenient for every purpose of common printing, which it would be scarcely possible to perform by its means; but when we discover that the inventor had probably in view the apparatus which he constructed the next year for the Bank of England, for numbering and dating their notes, we shall be aware that the means were admirably adapted to the end; a single line only being here wanted at once, in which a single figure was to be changed at each step, and that in a regular order. In fact, during the immense temporary circulation of one and two pound notes, the Bank has been able, by this machinery, under the management of about twenty clerks, to perform the labour of 120, who were before required for the purpose.

Mr Bramah procured a patent in 1809 for a mode of making and holding pens for writing, calculated to save the substance of the quill, by cutting a number of pens out of it, instead of a single one; and those who are not in the habit of making their own pens may often find a convenience in the portable form in which this and other similar "pterophori" are arranged. In 1812 he brought forward his patent for the construction of main pipes, to be carried through the principal streets of a metropolis, of sufficient thickness to withstand a great force, to which the water within them is intended to be subjected, by proper pumps, furnished with air-vessels; so that the water may not only be ready for the immediate extinction of fires, without the necessity of bringing an engine to the spot, but may also furnish a convenient moving power for various mechanical purposes, such as raising weights, by means of tubes sliding out of each other, like those of a telescope. He observes that he has frequently had occasion to employ a hydrostatic pressure, in many of his operations, equivalent to that of a column of water 20,000 feet high, which is about four tons for every square inch. He also asserts that he can form 500 tubes, each five feet long, capable of sliding within each other, and of being extended, in a few seconds, by the pressure of air forced into them, to a length of 2500 feet; and, with a power of this kind, he seems to have imagined that he could raise wrecks, and regulate the descent of weights of various descriptions.

His improvements in wheel-carriages, for which he obtained a patent in 1814, consisted in fixing each wheel to a separate movable axis, having its bearings at two distinct points of its length, but loosely inclosed between these points in a cylinder filled with oil; and, in some cases, he proposes to fix the opposite wheels to the same axis, though with a power of turning very stiffly round it, in order to lessen the lateral motion of the shafts in very rough roads. He also suggests the use of pneumatic springs, formed by pistons, sliding in cylinders, as a substitute for common springs of metal.

The purpose of Mr Bramah's last patent was the prevention of the dry rot, by laying on the timber meant to be preserved from it, a thin coat of Parker's Roman cement, much diluted with water; but he does not appear to have pursued this experiment, having transferred his right in the invention to other hands.

In addition to the seventeen patents which have been mentioned, he took out two or three others of less importance, at different times; besides a variety of contrivances, which he did not think it necessary to appropriate to himself by a legal privilege. Mr Nicholson has mentioned a double plunger for a forcing pump, as described to him by Mr Bramah (*Nich. Jour.* vol. vii. p. 50), which, in the form he has delineated, is certainly possessed of no particular advantage, producing only with a large ap-

paratus the effect of a much smaller. Mr Bramah had erected, in the latter years of his life, some large machines at the Thames bank for sawing stones and timber; he had begun to devise some improvements in bridges and in locks for canals; and he had at one time been actually employed in the execution of some water-works belonging to the department of the civil engineer, which he completed with ability and with success. His great and various exertions appear in some measure to have exhausted the strength of his constitution; and his last illness was immediately occasioned by a severe cold, taken in the prosecution of his experiments on the tearing up of trees, made in Holt Forest. He died in his sixty-sixth year, on the 9th of December 1814.

Mr Bramah was a sincere believer in the doctrines of the Christian religion; and, notwithstanding his diversified avocations, he left several manuscript essays on religious subjects. In his moral character he was cheerful, benevolent, and affectionate; in his habits he was neat and methodical; and he knew well how to temper liberality with economy. He often kept his workmen employed more for their sake than his own, when the stagnation of trade deprived him of the means of disposing of the products of their labour. It is surely on the characters of such individuals that the wealth and prosperity of the British empire most essentially depend; an inventive imagination controlled by a sound judgment, an incessant activity of mind and body, a head that can direct, and a heart that can feel, are the genuine sources of that practical superiority which is well known to distinguish the productions of our national industry. (*Life of Mr Bramah, by Dr Brown, in the New Monthly Magazine for April 1815.*)

(L. L.)

BRAMBANAN, a village of Java, nearly in the centre of the island, situated at the foot of a range of mountains on the north that run east and west to a great extent. It is noted for the remains of Hindu images, temples, and inscriptions, which are spread over an extent of ten miles. The most remarkable of those ruins are known under the name of the Thousand Temples, which constitute a square group of buildings, each side measuring 250 paces. One large temple stood in the centre of the square, which was surrounded at equal distances by three square rows of smaller ones, the rows being but a few feet distant from each other. At each of the four cardinal points, where there appear to have been gates, were two gigantic statues, each of them with a mace in its hand, and a snake twisted round its body. The inside walls of the large temple were adorned with figures of the conch shell, of water-vases, and of the sacred lotus, all denoting a Hindu origin. In these temples are figures, and other figures in relief are sculptured on the walls. They are all built of hewn granite, admirably cut and polished, and fitted into each other by means of a prominence in the upper stone, which fits into a groove on the upper surface of the stone underneath. Great skill is displayed in the architecture of the roof, which, like the rest of the building, is of hewn granite. The deepest mystery hangs over these ruins. They confirm the tradition, that at some former era a nation must have flourished in these islands, more advanced in the arts of civilization than the modern Javanese. But there is not the slightest evidence to show at what period those immense buildings were constructed. A Javanese manuscript asserts that it was in the Javanese year 1188, which corresponds to the year of the Christian era 1261.

BRAMBER, a small hamlet of twenty houses, in the rape of the same name in the county of Sussex, whence two members are returned to parliament. These burghage-houses belong to the Duke of Rutland and Lord Calthorpe, and of course confer on them the patronage.

Brambanan.

Bramhall
||
Brandenburg.

BRAMHALL, Dr JOHN, archbishop of Armagh, was born of an ancient family at Pontefract in Yorkshire about the year 1593. He was invited to Ireland by the lord deputy Wentforth, and soon afterwards obtained the archdeaconry of Meath, the best in that kingdom. In 1634 he was made bishop of Londonderry, a see which he improved very much; but the greatest service he rendered to the church of Ireland consisted in getting, with the deputy's assistance, several acts passed for abolishing fee-farms and recovering impropriations, by which, as well as by other means, he regained to the church in the space of four years L.30,000 or L.40,000 a year. In the convocation he prevailed upon the church of Ireland to unite in the same faith with the church of England, by adopting the thirty-nine articles of the latter; and would willingly have introduced the English canons, but could only prevail on their accepting such as were deemed proper. Articles of treason were exhibited against him in the Irish parliament; and at the treaty of Uxbridge in 1644, the English parliament made it a preliminary article, that Bishop Bramhall, with Archbishop Laud, and others, should be excepted from the general pardon. Upon this he went abroad; but, on the restoration, he was appointed archbishop of Armagh, primate and metropolitan of all Ireland, and was chosen speaker of the House of Lords. He died in 1663. He was the author of several works, which are collected in one volume folio.

BRAMPTON, a market-town of Eskdale Ward, in the county of Cumberland, 311 miles from London. It is an old town, of some note in former ages, and is still the head of the barony of Gillsland. It stands on the river Irthing, one mile from the Picts' wall. It has a large market on Tuesday, and a smaller one on Saturday, and several fairs to which the Scotch drovers repair with their cattle. The inhabitants amounted in 1801 to 1682, in 1811 to 2043, and in 1821 to 2448.

BRANAU, a small city in the Austrian province of Upper Ens, in the circle of Inviertel. It is situated on the banks of the Inn, and has manufactories of cloth and of paper. Long. 12. 52. 40. E. Lat. 48. 14. N.

BRANCHIDÆ, in *Grecian Antiquity*, priests of the temple of Apollo, at Didymus, in Ionia. They opened to Xerxes the temple of Apollo, and suffered him to carry away the riches; after which, thinking it unsafe to stay longer in Greece, they fled to Sogdiana, upon the frontiers of Persia, where they built a city called by their own name. But they did not escape the punishment of their crime; for on the conquest of Darius, Alexander the Great, informed of their treachery, put them all to the sword, and razed their city, thus summarily visiting the impiety of the fathers upon their posterity.

BRAND SUNDAY, *Dimanche des Brandons*, in French ecclesiastical writers, denotes the first Sunday in Lent, which is thus called on account of an ancient practice in the Lyonnais, where the peasants, in the night of this day, walked about their orchards, gardens, and other places, with torches lighted, or fire-brands in their hands; visiting every tree, addressing them one after another, and threatening that if they did not bear fruit well the ensuing season they should be cut down to the ground and burnt. This is evidently a relic of Paganism, and similar to what was practised by the ancient idolaters in the month of February, called *Februarius*, a *februando*.

BRANDENBURG, one of the larger provinces into which the kingdom of Prussia is divided, and the division from which that powerful monarchy originally sprung. It was at first denominated a marquisate; then the electoral dignity was added to the reigning family; and afterwards, by the acquisition of Prussia, Brandenburg became a portion of the kingdom so called. It is bounded on the

north by Mecklenburg, Pomerania, and West Prussia; on the east by Posen and Silesia; on the south by the kingdom of Saxony and the Saxon duchies; and on the west by Anhalt-Dessau, the province of Saxony, and Hanover. The extent is about 15,360 square miles, or near 10,000,000 English acres. It is divided into two circles, Potsdam and Frankfort, which are of nearly equal extent. The civil inhabitants, by the census of 1817, were 1,266,765; but, like those of all the other parts of Prussia, they have rapidly increased, and at the end of 1826 they were 1,479,482. The far greater part of the people are of the Lutheran church, but mixed with Catholics, Calvinists, and other sects, all of which are entitled to equal rights. The whole of the Catholics and smaller sects, including the Jews, do not exceed 30,000 persons. The entire province is nearly a sandy plain, but interspersed with a few fertile spots; and a considerable portion of it is covered with woods. It is generally well watered by streams, most of which empty themselves into the Elbe or the Oder. The chief agricultural product is rye, with some wheat, barley, oats, and buck-wheat. Fruit of all kinds is abundant, as well as culinary vegetables; and considerable quantities of hemp, flax, and hops are raised. The climate is cold and raw in winter, and excessively hot in summer. The manufactures are chiefly confined to Berlin and the other cities; but the rural inhabitants are employed in spinning or weaving, and produce much linen cloth.

BRANDENBURG, a city of Prussia, chief of the circle of the West Havell, in the province of its own name. It is an old place, on the banks of the Havell, by which it is divided into the new and the old town. It contains an ancient cathedral, six other churches, some charitable institutions, 1320 houses, and (in 1817) 12,004 inhabitants, occupied in making various goods of cotton, woollen, linen, and leather, and in breweries and distilleries. Long. 12. 8. 10. E. Lat. 54. 52. 45. N.

BRANDEUM, in ecclesiastical writers, a linen cloth or veil put over the tombs of the apostles Peter and Paul, and left there for some time, by which it is supposed to acquire a degree of sanctity, entitling it to be worshipped as a relic; and as such it was frequently sent by the pope as a present to some prince. In this sense Brandeum is the same with what was otherwise called *sanctuarium*, *sudarium*, *orarium*, and *velum*. The use of brandea was introduced as a means of diffusing and propagating the virtues and influences of relics, without moving, or in any way impairing, the substance of them; the translation of relics in early days being strictly forbidden.

BRANDING, on the face or hand, denotes a punishment inflicted by law for various offences, by burning with a hot iron, after the offender has been admitted to benefit of clergy.

BRANDON, a town in the hundred of Lachford, in the county of Suffolk, 78 miles from London, on the river Little Ouse, by which there is a communication with the sea at Lynn, and much corn is forwarded. The inhabitants amounted in 1801 to 1148, in 1811 to 1360, and in 1821 to 1770.

BRANDRITH denotes a trevet or other iron stand, whereon to set a vessel over the fire.

BRANDRITH, among builders, denotes a fence or rail about the mouth of a well.

BRANDT, GERARD, a learned divine of the reformed religion, was born at Amsterdam in 1626, and was successively minister in several places of the Netherlands. He wrote some works, particularly *A History of the Reformation of the Netherlands*, Amsterdam, 1671-74, in 2 vols. 4to; *The Life of Admiral Ruyter*; *An Account of the Trial of Barneveldt, Hoogerbeets, and Grotius*, in 1618,

Rotterdam 1619, 4to; and *Oratio Funeris Cornelii Hoofftii, Satrapæ Mudani*, Amsterdam, 1648; all, except the last, in the Flemish language. He died at Rotterdam in 1685.

BRANDY, a spirituous and inflammable liquor, extracted from wine and other liquors by distillation. The wine-brandy of France is esteemed the best in Europe. It is distilled wherever wine is made, and for this purpose pricked rather than good wine is employed. The chief brandies for foreign trade, and those accounted best, are the brandies of Bourdeaux, Rochelle, Cognac, Charenton, the Isle of Rhé, Orleans, the county of Blaisois, Poitou, Touraine, Anjou, Nantes, Burgundy, and Champagne.

BRANK, an instrument formerly used in some parts of Scotland, and in Staffordshire, for correcting scolding women. It was a sort of head-piece, which opened and inclosed the head of the shrew, while an iron, sharp as a chisel, entered the mouth, and subdued the unruly member within. Thus harnessed, the offender was led in triumph through the streets. Dr Plott, in his History of Staffordshire, has favoured the world with a minute description and figure of the instrument, which is there called a *scolding-bridle*; and he assures us that he looks upon it "as much to be preferred to the ducking-stool, which not only endangers the health of the party, but also gives the tongue liberty betwixt every dip; to neither of which (he adds) this is at all liable."

BRASIDA, an anniversary solemnity at Sparta, in memory of Brasidas, a Lacedemonian captain, famous for his achievements at Methone, Pylos, and Amphipolis. It was celebrated with sacrifices and games, in which none were permitted to attend but free-born Spartans. Whosoever neglected to be present at the solemnity was fined.

BRASIDAS, a celebrated general of the Lacedemonians about 424 years before the birth of Christ. He defeated the Athenians by land and sea, took many places, and rendered his native country formidable to all the neighbouring states. He repulsed the Athenians in their attempted surprise of Amphipolis, but died of the wounds he received in that battle. See *ATTICA*.

BRASS, in *Chemistry and Manufactures*, an alloy of copper and zinc. This name, however, has not been exclusively applied to the alloy of these metals; for the gun-metal, which has been also called brass, is an alloy of copper with tin. The same alloy, with more tin, is used in machinery, and is preferred to the alloy of copper and zinc, on account of its greater hardness.

It appears from the analysis of the brass of the ancients that it was an alloy of copper and tin. A small portion of tin gives to copper great hardness, and renders it capable of bearing much greater resistance. A larger portion of tin gives increased hardness, but is less fitted to bear a straining resistance, on account of its brittleness. Its elasticity is very great, which fits it for bells. In this state it is called bell-metal; and with a still greater proportion of tin it forms an alloy employed for the mirrors of reflecting telescopes. The alloy of copper with tin is easily distinguished from that with zinc, from the agreeable colour of the latter, which varies with the proportions of the metals. Pinchbeck has the least proportion of zinc. Common brass has more zinc, and the gold-coloured alloy called prince's metal contains a still greater proportion of zinc. An alloy of copper with a very large proportion of zinc is used for the common white metal buttons.

The various alloys of copper with tin and zinc forming the different kinds of brass, are to be considered as chemical compounds, and, of course, governed by the same laws of definite proportions which obtain in the more conspicuous compounds. On these principles, which cannot be doubted, we have an unerring rule for uniting these and

other metals in the best proportions, the weights of their atoms being previously known.

The weight of the atom of copper being 8, tin 7.35, and zinc 4, the following tables exhibit the proportions of the various alloys, expressed in atoms, and their proportions by weight, the third column pointing out the colour and character of the resulting compound. CZ and T are to represent the atoms of the metals respectively.

COMPOUNDS OF ZINC WITH COPPER.

Atoms.	Proportions by Weight.	Character and Colour of the Compounds.
C+Z	1 to 2	The best proportions for common brass.
C+2Z	1 to 1	The alloy called prince's metal, of a beautiful gold colour.
C+3Z	2 to 3	Of a paler yellow, very little malleable.
C+4Z	1 to 2	Still of a lighter colour, and not malleable.
C+5Z	2 to 5	Yellowish white, and brittle.
C+6Z	1 to 3	Very brittle, nearly white.
2C+Z	4 to 1	A very malleable brass used in watch-work.
3C+Z	6 to 1	An alloy much harder than copper, and inclining to its colour.

COMPOUNDS OF TIN WITH COPPER.

Atoms.	Proportions by Weight.	Character and Colour of the Compounds.
T+C	11 to 12	A very brittle and rather white alloy.
2T+C	11 to 6	Still more brittle and more white.
3T+C	11 to 4	Very white, used for speculums.
4T+C	11 to 3	Coarse-grained, and too brittle for any purpose.
T+2C	11 to 24	A yellowish alloy, very hard and sonorous.
T+3C	11 to 36	Bell metal.
T+4C	11 to 48	A very hard alloy, used for some culinary vessels.
T+5C	11 to 60	Softer, but not malleable.
T+6C	11 to 72	Still increases in softness, and of a yellower colour.
T+7C	11 to 84	Used for some purposes in machinery.
T+8C	11 to 96	An alloy used for cannon.
T+9C	11 to 108	More common for cannon and machinery, and used for bronze statues.

Hitherto the proportions of these alloys have depended upon the practice of workmen, guided by numerous trials; but what confirms the law of definite proportions, is the necessity of adhering to fixed proportions, ascertained by trial. By attending to the proportions pointed out in the above tables, the most striking and proper compounds will be produced, without the trouble of trying. Any intermediate proportions will, doubtless, be marked by defective colour, irregular crystallization, or imperfect malleability.

Although the most direct way of forming these different kinds of brass is by immediately combining the metals together, one of them, which is most properly called brass, was manufactured long before zinc, one of its component parts, was known in its metallic form. The ore of the

Brass.

latter metal was cemented with sheets of copper, charcoal being present; and the zinc was united with the copper, without becoming visible in a distinct form. The same method is still practised for making brass.

Brass making.

The materials used in making brass are copper in small round masses, produced by passing the melted metal through an appropriate vessel into water, in which state it is called shot copper; and calamine, an ore of zinc. This latter substance is a carbonate of zinc, often containing some oxide of iron, which gives it a reddish appearance. As it is chiefly found in combination with lead, the lumps frequently contain more or less gallena, which requires to be separated by the same means as those employed for purifying lead ore. The calamine is first reduced to powder, and the lead is then separated by washing. When the calamine is separated, reduced to powder, and sifted, it is heated upon the hearth of a reverberatory furnace. This expels the volatile matter, which is principally water and carbonic acid. What remains is principally oxide of zinc, abounding with some earthy matter, and probably much carbonic acid, which is not all expelled by the heat. The calamine thus prepared, charcoal powder, and copper, are the materials to be operated upon. The proportions in which they are mixed together are equal weights of copper and prepared calamine, and $\frac{1}{10}$ th their weight of powdered charcoal.

This mixture, intimately blended, is compressed into a crucible of the form of fig. 3, Plate CXXVII. One of these crucibles holds about 100 lbs. of brass when the process is finished; but as this consists of the pure copper and zinc, the pot, when charged, will contain of copper 66·3 lbs., of calamine 63 lbs., and of charcoal powder 13 lbs. When the crucible is filled, the contents should be covered with a mixture of clay sand and horse-dung, in order to defend the metals and charcoal from the action of the air. When this covering is strictly attended to, less charcoal powder may be employed, and a larger dose of the other ingredients may be put in its place; but it is generally the most defective part of the process.

Fig. 1, Plate CXXVII., is a plan of the furnace. The part AB is taken at the level EF, showing the opening into the furnace on the ground floor at *a* and *b*; while *c* and *d* are horizontal flues leading to the chimney *f*, which may be cut off from the same by the dampers seen in the dark part of the flue. CD, in the same figure, is a plan on the level GH, where the pots rest upon the cast-iron plate on the bottom *x*, *y*.

Fig. 2 is an elevation and section of the same furnace. AB shows a front view of the pyramidal chimney, and the archway opening into it. CD is a section of the same, through the middle of the fire-place II. R, P, Q, is a vaulted passage going across the building, and open at both ends for the admission of air, which passes through the openings in the arch, into the fires. The bottom of the furnace is not a common grate, but a thick plate of cast-metal, perforated with holes for the air to pass through; one hole being between each pot, as they are seen arranged in fig. 1, at I, I, and also in the section at *x*, *y*. When the pots are put upon the plate, the fire is not placed immediately upon them, as it would not only injure them, but displace the covering. To prevent this, the pots are first covered by some dried heath or common brambles, which defend them for a time, when the fuel is thrown in. By the time the brambles are consumed the coal will have coked upon the pots, and thus act as a defence for the rest of the process. The fire is kept up from twelve to twenty hours at the Cheudle brass-works in Staffordshire, from which these drawings were taken. They cast twice in the twenty-four hours.

After the refuse is skimmed off, the melted brass is

cast into ingots if sold for melting over again, and into plates if intended to be rolled into sheets or made into wire. The plates are cast between large blocks of Cornwall stone. The lower stone is fixed, and the face made even and smooth, by filling up the recesses of the rough stone with fine sand. The upper stone is similarly prepared, and is suspended over the fixed one. The height and breadth of the place to receive the metal is limited by iron bars laid on the lower stone. The upper stone is then let down upon the bars. The lower stone is a little longer than the upper one, and projects to the front. Being a little higher in that part, it forms a lip or mouth-piece for receiving the metal. The flat sides of the cast plate are therefore bounded by the surface of the stones, and the edges of these by the bars above mentioned. The ingot moulds are recesses in blocks of cast-iron, open on one side.

The most certain and correct method of forming brass and the other compounds expressed in the table above given, is by immediately uniting the metals in given weights. It should, however, be observed, that it will be found difficult to introduce zinc into melted copper. The best way of uniting it with copper, in the first instance, is to introduce the copper in thin slips into the melted zinc, till the alloy requires a considerable heat to fuse it, and then to unite this alloy with the melted copper.

Corinthian Brass, famous in antiquity, is a mixture of gold, silver, and copper. Lucius Mummius having sacked and burnt the city of Corinth, 146 years before Christ, it is said this metal was formed from the immense quantities of gold, silver, and copper, with which that city abounded, having been melted and run together by the violence of the conflagration.

BRASS, in the glass trade. Thrice calcined brass is a preparation employed by glassmen to give many very beautiful colours to their work. The manner of preparing it is this: Having placed thin plates of brass on tiles on the leet of the furnace, near the occhis, let it stand to be calcined there for four days, and it will become a black powder sticking together in lumps. Pulverize this, sift it fine, and recalcine it during four or five days more; at the end of which time it will not stick together, but remain a loose powder of a russet colour. This is to be calcined a third time in the same manner; but great care must be taken in the third calcination that it be neither overdone nor underdone. The way to be certain when it is right, is, to try it several times in glass while melting. If it causes the glass, when well purified, to swell, boil, and rise, it is properly calcined; if not, it requires longer time. This, according to the different proportions in which it is used, produces a sea-green, an emerald-green, or a turquoise colour.

Brass, by long calcination alone, and without any mixture, affords a fine blue or green colour for glass; but there is a method of calcining it also with powdered brimstone, so as to make it afford a red, a yellow, or a chalcidony colour, according to the quantity and other variations in the using of it. This method of calcination is the following: Cut thin plates of brass into small pieces with shears, and lay them *stratum super stratum*, with alternate beds of powdered sulphur, in a crucible; calcine this for twenty-four hours in a strong fire, then powder and sift the whole, and finally expose the powder upon tiles for twelve days to a reverberating furnace, at the end of which time powder it fine and keep it for use. The glass-makers have also a method of procuring a red powder from brass by a more simple calcination, which serves for many colours. The method of preparing it is this: They put small and thin plates of brass into the arches of the glass furnaces, and leave them there till they are sufficiently calcined,

which the heat in that place, not being sufficient to melt them, does in great perfection. The calcined matter, powdered, is of a dusky red, and requires no further preparation.

BRASS-COLOUR, one prepared by the braziers and colourmen to imitate brass. There are two sorts of it, the red brass or bronze, and the yellow or gilt brass. The latter is made only of copper-filings, the smallest and brightest that can be found; with the former it is usual to mix some red ochre, finely pulverized; and both are used with varnish. In order to make a fine brass that will not take any rust or verdigris, it must be dried with a chafing-dish of coals as soon as it is applied. The finest brass-colour is made of powdered brass imported from Germany, diluted into a varnish, which is prepared and used after the following manner: The varnish is composed of one pound four ounces of spirits of wine, two ounces of gum-lac, and two ounces of sandarac; these two last drugs being pulverized separately, and afterwards put to dissolve in spirit of wine, and care being taken to fill the bottle but half full. The varnish being made, mix a quantity of it with the pulverized brass, and apply it with a small brush to that which it is intended to brass over. But too much must not be mixed at once, because the varnish being very apt to dry, it would not be possible to employ it all soon enough. It is therefore better to make the mixture at several times. In this manner are brased over figures of plaster, which look almost as well as if they were of cast brass.

BRASS LEAF is made of copper, beaten into very thin plates, and afterwards rendered yellow. The German artists, particularly those of Nuremberg and Augsburg, are said to possess the best method of giving to these thin plates of copper a fine yellow colour like gold, by simply exposing them to the fumes of zinc, without any real mixture of it with the metal. These plates are cut into little pieces, and then beaten out fine like leaves of gold; after which they are put into books of coarse paper and sold at a low price for the vulgar kinds of gilding. The parings or shreds of these very thin yellow leaves, being well ground on a marble plate, are reduced to a powder similar to gold, which serves to cover, by means of gum-water or some other glutinous fluid, the surface of various mouldings or pieces of curious workmanship, giving them the appearance of real bronze, and even of fine gold, at a very trifling expense, because the gold colour of this metallic powder may be easily raised and improved by stirring it in a wide earthen basin over a slow fire.

BRASSICA CABBAGE. See **HORTICULTURE**.

BRASSICAVIT, or **BRACHICAVIT**, in the manège, means a horse whose fore legs are naturally bent archwise, and who is so called by way of distinction from an arched horse, whose legs are bowed by hard labour.

BRAULS, Indian cloths with blue and white stripes. They are otherwise called *turbans*, because they serve to cover those ornaments of the head, particularly on the coast of Africa.

BRAUNFELS, a town in the Prussian province of Coblenz, in the circle of Wetzlar-Braunfels. It belongs to the duke of that name, formerly a prince, but now mediatised. The castle, on the top of a sugar-loaf hill overlooking the city, is one of the most picturesque objects in Germany. The foot is washed by the Iserbach, and the town is on the side of the hill, so that every part of it is commanded by the castle or ducal residence. It contains about 1500 inhabitants.

BRAUNSBURG, a circle in the Prussian government of Königsberg and province of East Prussia. It extends over 392 square miles, and contains three cities and seventeen parishes, with 30,863 inhabitants. Though very woody,

it produces much good corn and flax. The city, whose name it bears, stands near the Frische Haff, which communicates with the Baltic Sea at Pillau. It contains four Catholic churches and one Lutheran, with 645 houses and 6194 inhabitants. Long. 9. 44. 35. E. Lat. 54. 19. 25. N.

BRAURONIA, in *Grecian Antiquity*, a festival in honour of Diana, surnamed *Brauronia*, from its having been observed at Brauron, an Athenian borough. This festival was celebrated once in five years, under the management of ten men, called in Greek *ἱερονόμοι*. The victim offered in sacrifice was a goat, and it was customary for certain men to sing portions of Homer's Iliad. The most remarkable persons at this solemnity were young virgins, habited in yellow gowns, and consecrated to Diana. It was unlawful for any of them to be above ten or under five years of age.

BRAWN, the flesh of a boar soused or pickled. For this end the boar should be old, because the older he is the more horny will the brawn be. The method of preparing brawn is as follows: The boar being killed, it is the flitches only, without the legs, that are made brawn; the bones of these are to be taken out, and the flesh sprinkled with salt and laid in a tray, that the blood may drain off; then it is to be salted a little, and rolled up as hard as possible. The length of the collar of brawn should be as much as one side of the boar will bear, so that when rolled up it may be nine or ten inches in diameter. The collar being thus rolled up, it is to be boiled in a copper or large kettle till it become so tender that a straw may be run through it, and then set by till it is thoroughly cold, and put into a pickle prepared in the following manner: For every gallon of water add a handful or two of salt and as much wheat-bran; boil them together, then drain the bran clear off from the liquor, and when it is quite cold put the brawn into it.

BRAY, SIR REGINALD, an architect and politician, was the second son of Sir Richard Bray, one of the privy council to King Henry VI. Sir Reginald was instrumental in the advancement of King Henry VII. to the throne of England, and was greatly in favour with that prince, who bestowed honours and wealth upon him. His skill in architecture appears from Henry VII.'s chapel at Westminster, and the chapel of St George at Windsor; he had a principal concern and direction in building the former, and in finishing and bringing to perfection the latter, to which he was also a liberal benefactor. He died in 1501, and was interred in the above chapel, probably under the stone where Dr Waterland lies; for, on opening the vault to admit the body of that gentleman, who died in 1740, a leaden coffin of ancient form was found, which, by other appearances, was judged to be that of Sir Reginald, and was, by order of the dean, immediately arched over.

BRAY, *Dr Thomas*, a learned and pious divine, was born at Marton, in Shropshire, in the year 1656, and educated at Oxford. He was at length presented to the vicarage of Over-Whitacre, in Warwickshire; and in 1690 he obtained the rectory of Sheldon, where he composed his Catechetical Lectures. These procured him such reputation, that Dr Compton, bishop of London, pitched upon him as a proper person to model the infant church of Maryland, and establish it upon a solid foundation; and for that purpose he was invested with the office of commissary. He now engaged in several important undertakings. He caused sums to be raised for purchasing small libraries for the use of the poor ministers in the several parts of our plantations; and the better to promote this design, he published two books. One of these is entitled *Bibliotheca Parochialis*, or a scheme of such theological and other heads as seem requisite to be perused or

occasionally consulted by the clergy, together with a catalogue of books which may be profitably read on each of those points; the other, *Apostolical Charity*, its nature and excellency considered. He endeavoured to get a fund established for the propagation of the gospel, especially among the uncultivated Indians; and by his means a patent was obtained for erecting the corporation called The Society for the Propagation of the Gospel. By his industry he also procured relief for prisoners, and formed the plan of the society for the reformation of manners, charity schools, and other like purposes. He wrote *Martyrology*, or *Papal Usurpation*, in one volume, folio; *Directorium Missionarium*; and other works. Dr Bray died in 1730, aged seventy-three.

BRAY, a small sea-port town of Ireland, in the county of Wicklow, and province of Leinster, situated on the south side of the river Bray. It is ten miles distant from Dublin.

BRAZEN SEA, in *Jewish Antiquity*, one of the sacred utensils in the temple of Solomon. It was cast in the

plain of Jordan, and removed from thence into the inner court of the temple, where it was placed upon twelve oxen, three of which looked towards each quarter of the world. It was ten cubits from the one brim to the other, five cubits in height, and thirty cubits in circumference, and contained three thousand baths. The brim of it was perfectly round, and so it continued in the two upper cubits; but below the brim, in the three lower cubits, it was square. It was a hand-breadth in thickness, and the brim was wrought like the brim of a cup, with flowers of lilies. About the body of this huge vessel were two borders of engravings, representing the heads of oxen in demi-relief, and out of these some suppose the water to have issued. This brazen or molten sea was designed for the priests to wash themselves in before they performed the service of the temple. Water was supplied through a pipe out of the well Etam.

BRAZIER, an artificer who makes and deals in all kinds of brass ware.

B R A Z I L.

IN presenting an account of this extensive and important country, we shall, *first*, give a brief historical sketch of the progressive discovery of its coasts and interior, of its gradual settlement, and of the auspices under which its social institutions have developed themselves; *secondly*, a condensed view of its physical geography, meteorology, and natural products; and, *thirdly*, a similar view of its inhabitants, their form of government, moral and intellectual culture, and agricultural, manufacturing, and commercial industry.

History.

I. *History*.—Brazil was discovered in 1499, by Vincent Yañez Pinçon, a companion of Columbus. He descried the land near Cape St Augustine, and sailed along the coast as far as the river Amazons, whence he proceeded to the mouth of the Orinoco. He made no settlement, but took possession of the country in the name of the Spanish government, and carried home, as specimens of its natural productions, some drugs, gems, and Brazil wood. Next year the Portuguese commander, Pedro Alvarez Cabral, appointed by his monarch to follow the course of Vasco de Gama in the east, was driven, by adverse winds, so far from his track, that he reached the Brazilian coast, and anchored in Porto Seguro (lat. 16° S.) on Good Friday. On Easter-day an altar was erected, mass celebrated in presence of the natives, the country declared an apanage of Portugal, and a stone cross erected in commemoration of the event. Cabral dispatched a small vessel to Lisbon, to announce his discovery, and, without forming any settlement, proceeded to India.

On the arrival of the news in Portugal, Emanuel invited Amerigo Vespucci to enter his service, and dispatched him with three vessels to explore the country. This navigator's first voyage was unsuccessful; but in a second he discovered a safe port, the site of which is not accurately known, to which he gave the name of All-Saints. He remained there five months, and maintained a friendly intercourse with the natives. Some of the party travelled forty leagues into the interior. Vespucci erected a small fort, and leaving twelve men, with guns and provisions, to garrison it, embarked for Portugal; having loaded his two ships with Brazil wood, monkeys, and parrots.

The poor and barbarous tribes of Brazil, and their country, the mineral riches of which were not immediately discovered, offered but few attractions to a government into the coffers of which the wealth of India and Africa was flowing. Vespucci's settlement was neglected. For nearly

thirty years the kings of Portugal paid no further attention to their newly-acquired territory, than what consisted in combating the attempts of the Spaniards to occupy it, and dispersing the private adventurers from France, who sought its shores for the purposes of commerce. The colonization of Brazil was prosecuted, however, by subjects of the Portuguese monarchy, who traded thither chiefly for Brazil wood. It was convenient for these traders to have agents living among the natives; and adventurers were found who were willing to take up their abode with them. The government also sought to make criminals of some use to the state, by placing them in a situation where they could do little harm to society, and might help to uphold the dominion of their nation. The utter want of any legal check upon these earliest European settlers, combined with the ferocious characters of many of them, and the hardening influence of their feuds with the native cannibals, were anything but favourable to the morals of the infant empire.

The first attempt on the part of a Portuguese monarch to introduce an organized government into his dominions, was made by Joam III. He adopted a plan which had been found to succeed well in Madeira and the Azores; dividing the country into hereditary captaincies, and granting them to such persons as were willing to undertake their settlement, with unlimited powers of jurisdiction, both civil and criminal. Each captaincy extended along fifty leagues of coast. The boundaries towards the interior were undefined.

The first settlement made under this new system was that of S. Vincente. Martim Affonso de Sousa, having obtained a grant, fitted out a considerable armament, and proceeded to explore the country in person. He began to survey the coast about Rio Janeiro, to which he gave that name because he discovered it on the first of January 1531. He proceeded south as far as La Plata, naming the places he surveyed on the way from the days on which the respective discoveries were made. He fixed upon an island, in latitude 24½° south, called by the natives Guaibe, for his settlement. The Goagnazes, or prevailing tribe of Indians in that neighbourhood, as soon as they discovered the intentions of the new comers to fix themselves permanently there, collected for the purpose of expelling them. Fortunately, however, a shipwrecked Portuguese, who had lived many years under the protection of the principal chief, was successful in concluding a

Brazil

Brazil.

treaty of perpetual alliance between his countrymen and the natives. The good understanding thus happily established was long preserved. Finding the spot chosen for the new town inconvenient, the colonists removed to the adjoining island of S. Vincente, from which the captaincy derived its name. An unsuccessful expedition was made into the interior in search of mines. Nevertheless the colony prospered. Cattle and the sugar-cane were at an early period introduced from Madeira, and here the other captaincies supplied themselves with both. The founder of the colony was soon removed from the active superintendence of its progress, by being appointed governor-general of India; but on his return to Portugal he watched over its welfare, sending out supplies and settlers, and leaving it at his death in a flourishing condition to his son.

Pero Lopes de Sousa received the grant of a captaincy, and set sail from Portugal at the same time as his brother, the founder of S. Vincente. He chose to have his fifty leagues in two allotments. That to which he gave the name of S. Amaro adjoined S. Vincente, the two towns being only three leagues asunder. The other division lay much nearer to the line between Paraíba and Pernambuco. He experienced considerable difficulty in founding this second colony, from the strenuous opposition of a neighbouring tribe, the Petiguares; but at length he succeeded in clearing his lands of them; and not long afterwards he perished by shipwreck. The extreme proximity of his first settlement at S. Amaro to his brother's at S. Vincente was at first advantageous to both; but the former coming after his death into the hands of strangers, their interfering and contested boundaries gave rise to much trouble and litigation.

Rio Janeiro was not settled till a later period; and for a considerable time the nearest captaincy to S. Amaro, sailing along the coast northwards, was that of Espírito Santo. It was founded by Vasco Fernandes Coutinho, who having acquired a large fortune in India, sunk it in this scheme of colonization. He carried with him no less than sixty fidalgos. They named their town by anticipation, Our Lady of the Victors; but it cost them some hard fighting with the Goagnazes to justify the title. Having defeated these savages, the colonists carried on the building with spirit, planted canes, and established four sugar-works; and Coutinho seeing every thing prosperous, returned to Lisbon to enlist more colonists, and to make preparations for an expedition into the interior in search of mines.

Pedro de Campo Tourinho, a nobleman and excellent navigator, received a grant of the adjoining captaincy of Porto Seguro. This, it will be remembered, is the spot where Cabral first took possession of Brazil. Tourinho and his associates fortified themselves on the place where the capital of the presidency still stands. The Tupinoquins at first offered some opposition; but having made peace, they observed it faithfully, notwithstanding that the oppression of the Portuguese obliged them to forsake the country. In this guilt Tourinho is not implicated. That he had influence enough with the natives to induce many of them to collect and settle in villages, is a proof that he dealt justly by them. Sugar-works were established, and considerable quantities of the produce exported to the mother-country. It was found impossible, by reason of an endemic disorder, to rear kine in the province; but horses, asses, and goats, succeeded.

Jonge de Figueiredo, *Escrivam da Fazenda*, was the first donatory of the captaincy of the isles. His office preventing him from taking possession in person, he deputed the task to Francisco Romeiro, a Castilian. The Tupinoquins, the most tractable of the Brazilian tribes, made peace with the settlers, and the colony was founded

without a struggle. The son of the original proprietor sold the captaincy to Lucas Geraldês, who expended considerable wealth in improving it; and, in a short time, eight or nine sugar-works were established.

The coast from the Rio Francisco to the bay of Bahia was granted to Francisco Pereira Coutinho; and the bay itself, with all its creeks, was afterwards added to the grant. When Coutinho formed his establishment, where Villa Velha now stands, he found a noble Portuguese living in the neighbourhood, who, having been shipwrecked, had, by means of his fire-arms, raised himself to the rank of chief among the natives. He was surrounded by a patriarchal establishment of wives and children; and to him most of the distinguished families of Bahia still trace their lineage. The regard entertained by the natives for Caramuru (so he was called by them) induced them to extend a hospitable welcome to his countrymen; and for a time every thing went on well. Coutinho had, however, learned in India to be an oppressor, and the Tupinambas were the fiercest and most powerful of the native tribes. The Portuguese were obliged to abandon their settlement; but several of them returned at a later period, along with Caramuru, and thus a European community was established in the district.

A factory had, some time before the period at which these captaincies were established, been planted at Pernambuco. A ship from Marseilles took it, and left seventy men in it as a garrison; but being captured on her return, and carried into Lisbon, immediate measures were taken for re-occupying the place. The captaincy of Pernambuco was granted to Don Duarte Coelho Pereira as the reward of his services in India. It extended along the coast from the Rio St Francisco, northward to the Rio de Juraza. Duarte sailed with his wife and children, and many of his kinsmen, to take possession of his new colony, and landed in the port of Pernambuco. To the town which was there founded he gave the name of Olinda. The Cabetes, who possessed the soil, were fierce and pertinacious; and, assisted by the French, who traded to that coast, Coelho had to gain by inches what was granted him by leagues. The Portuguese managed, however, to beat off their enemies; and, having entered into an alliance with the Tobayanes, followed up their success. After this triumph the colony continued, with the exception of a brief interval, to enjoy peace, and to prosper during the life of its founder.

Attempts were made about this time to establish two other captaincies, but without success. Pedro de Goes obtained a grant of the territory between the captaincies of S. Vincente and Espírito Santo; but his means were too feeble to enable him to make head against the aborigines, and the colony was broken up after a painful struggle of seven years. Joam de Barros, the historian, obtained the captaincy of Maranhão. For the sake of increasing his capital, he divided his grant with Fernan Alvares de Andrada and Aires da Cunha. They projected a scheme of conquest and colonization upon a large scale. Nine hundred men, of whom one hundred and thirteen were horsemen, embarked in ten ships under the command of Aires da Cunha. But the vessels were wrecked upon some shoals about one hundred leagues to the south of Maranhão; and the few survivors, after suffering immense hardships, escaped to the nearest settlements, and the undertaking was abandoned.

By these adventurers, the whole line of Brazilian coast, from the mouth of La Plata to the mouth of the Amazons, had become studded at intervals with Portuguese settlements, in all of which law and justice were administered, however inadequately. Sufficient capital was in consequence attracted, between the year 1531, in which De

History.

Sousa founded the first captaincy, and the year 1548, to these colonies, to render them an object of importance to the mother country. Their organization, however, both in regard to their means of defence against external aggression and internal violence, was extremely defective. Portugal was distant, and the inhabited portions of each captaincy were too far asunder to be able to afford reciprocal assistance. They were surrounded by, and intermingled with, large tribes of savages. Behind them the Spaniards, who had an establishment at Assumption, had penetrated almost to the sources of the waters of Paraguay, and had succeeded in establishing a communication with Peru. Orellana, on the other hand, setting out from Peru, had crossed the mountains and sailed down the Amazons. Nor had the French abandoned their hopes of effecting an establishment on the coast. But the internal mismanagement of the Portuguese settlements was even worse than the inadequacy of their defensive force. The governor of every captaincy exercised uncontrolled authority; the property, honour, and lives of the colonists, were at the mercy of these feudal chieftains; and the people groaned under their oppression. If Portugal wished to preserve and profit by her colonies, it was evident that measures must be taken to ameliorate their institutions.

The obvious remedy for these evils was to concentrate the executive power, to render the petty chiefs amenable to one tribunal, and to confide the management of the defensive force to one hand. In order to this the powers of the several captains were revoked, whilst their property in their grants was reserved to them. A governor-general was appointed, with full powers, civil and criminal. The judicial and financial functions in each province were vested in the *Ouvidor*, whose authority in the college of finance was second only to that of the governor. In levying the dues of the crown, he was assisted by the *Juiz de Fora*. Every colonist was enrolled either in the *Milicias* or *Ordenanzas*. The former were obliged to serve beyond the boundaries of the province, the latter only at home. The *Milicias* were commanded by *Coroneis*, the *Ordenanzas* by *Capitães Mores*. Both were immediately under the governor. The chief cities received municipal constitutions; as in Portugal. Thome de Sousa was the first person nominated to the important post of governor-general. He was instructed to build a strong city in Bahia, and to establish there the seat of his government. In pursuance of his commission, he arrived at Bahia in April 1549, with a fleet of six vessels, on board of which were three hundred and twenty persons in the king's pay, four hundred convicts, and as many free colonists as swelled the number of adventurers to one thousand. Care had been taken for the spiritual wants of the provinces, by associating six Jesuits to the expedition.

Old Caramuru, who still survived, rendered the governor essential service, by gaining for his countrymen the good will of the natives. The new city was established where Bahia still stands. Within four months one hundred houses were built, and surrounded by a mud wall. Sugar plantations were laid out in the vicinity. During the four years of Sousa's government, there were sent out at different times supplies of all kinds; female orphans of noble families, who were given in marriage to the officers, and portioned from the royal estates; and orphan boys to be educated by the Jesuits. The capital rose rapidly in importance, and the captaincies learned to regard it as a common head and centre of wealth. The governor visited them, inspected their fortifications, and regulated the administration of justice. Meanwhile the Jesuits undertook the moral and religious culture of the natives, and of the scarcely less savage colonists. Strong opposition was at first experienced from the gross ignorance of the

Indians, and the depravity of the Portuguese, fostered by the licentious encouragement of some abandoned priests who had found their way to Brazil. Over these persons the Jesuits had no authority; and it was not until the arrival of the first bishop of Brazil in 1552 that any thing like an efficient check was imposed upon them. Next year Sousa was succeeded by Duarte da Costa, who brought with him a reinforcement of Jesuits, at the head of whom was Luis de Gran, appointed, with Nobrega the chief of the first mission, joint provincial of Brazil.

Nobrega's first act was one which has exercised the most beneficial influence over the social system of Brazil, namely, the establishment of a college on the then unreclaimed plains of Piratininga. The spot selected by him for the site of this establishment is on the ridge of the Serra do Mar, ten leagues from the sea, and thirteen from S. Vincente. It was named S. Paulo, and has been at once the source whence knowledge and civilization have been diffused through Brazil, and the nucleus of a colony of its manliest and hardiest citizens, which has sent out successive swarms of hardy adventurers to people the interior. The mode of education pursued by the Jesuits at S. Paulo was the same as that observed in all their other missions. Their good intentions were in part frustrated by the opposition of Duarte the governor; and it was not until 1558, when Mem de Sa was sent out to supersede him, that their enlightened projects were allowed free scope. This great man, comprehending better than his predecessor the system of these missionaries, went hand in hand with the ecclesiastics, during the whole of his government.

It has been observed above that Rio Janeiro was not colonized at the time when the rest of the coast was portioned out into captaincies. It was first occupied by French settlers. Nicholas Durand de Villegagnon, a bold and skilful seaman, having visited Brazil, saw at once the advantages which might accrue to his country from a settlement there. In order to secure the interest of Coligny, he gave out that his projected colony was intended to serve as a place of refuge for the persecuted Huguenots. Under the patronage of that admiral, he arrived at Rio Janeiro in 1558, with a train of numerous and respectable colonists. As soon, however, as he thought his power secure, he threw off the mask, and began to harass and oppress the Huguenots by every means he could devise. Many of them were forced by his tyranny to return to France; and ten thousand Protestants, ready to embark for the new colony, were deterred by their representations. Villegagnon, finding his force much diminished in consequence of his treachery, sailed for France in quest of recruits; and during his absence the Portuguese governor, by order of his court, attacked and dispersed the settlement. For some years the French kept up a kind of bush warfare; but in 1567 the Portuguese succeeded in establishing a settlement at Rio.

Mem de Sa continued to hold the reins of government in Brazil upon terms of the best understanding with the clergy, and to the great advantage of the colonies, for fourteen years. On the expiration of his power, which was nearly contemporary with that of his life, an attempt was made to divide Brazil into two governments; but, this having failed, the territory was re-united in 1578, the year in which Diego Laureço da Viega was appointed governor. At this time the colonies, although not yet independent of supplies from the mother country, were in a flourishing condition; but the usurpation of the crown of Portugal by Philip II. changed the aspect of affairs. Brazil, believed to be inferior to the Spanish possessions in mines, was considered of importance merely as an outpost to prevent the intrusion of foreign nations. It was consequently abandoned to comparative neglect for the period intervening

History. between 1578 and 1640, during which it continued an ap-panage of Spain. The population increased; and domestic enterprise and foreign invasion called forth the energies of the people; but, as far as the legislature was concerned, nothing was done.

No sooner had Brazil passed under the Spanish crown, than English adventurers directed their hostile enterprises against its shores. In 1586 Witherington plundered Bahia; in 1591 Cavendish burned S. Vincente; in 1595 Lancaster took Olinda. These exploits were the transient operations of freebooters. In 1612 the French attempted to found a permanent colony in the island of Marajó, where they succeeded in maintaining themselves till 1618. This attempt led to the erection of Maranhão and Para into a separate *Estado*. But it was on the part of the Dutch that the most skilful and pertinacious efforts were made for securing a footing in Brazil; and they alone of all the rivals of the Portuguese have left traces of their presence in the national spirit and institutions of Brazil.

The very imperfect constitution of the United Provinces was the cause why many of the executive functions were delegated to companies of mercantile adventurers. Among the offices properly appertaining to the government, the maintenance and defence of the Spice Islands had been intrusted to the East India Company. The success of that body suggested the establishment of a West India Company. Its charter secured to it a monopoly of the trade to America and the opposite coast of Africa, between the tropic of Cancer and the Cape of Good Hope. The company was taken bound to render an account of its proceedings every sixth year.

This body dispatched, in 1624, a fleet against Bahia. The town yielded almost without a struggle. The Dutch governor fortified his new acquisition; and his proclamation offering toleration and protection to all, collected around him a multitude of Indians, Negroes, and Jews. The fleet soon after sailed; a squadron being detached against Angola, with the intention of taking possession of that colony, in order to secure a supply of slaves. The Portuguese, in the meanwhile, who had fled at first in the hope of eluding what they conceived to be merely an incursion of pirates, began to collect for the purpose of expelling the permanent intruders; and the weakening of the Dutch force by the departure of the fleet inspired them with fresh courage. The descendants of Caramuru formed a link between the aborigines and the Portuguese which existed in no other part of Brazil. The consequence was, the hearty co-operation of all the natives against the invaders. The Dutch were obliged to capitulate in May 1625. The honours bestowed upon the Indian chiefs for their assistance in this war broke down in a great measure the barrier between the two tribes; and there is at this day a greater admixture of their blood among the better classes in Bahia than is to be found elsewhere in Brazil.

For some years the Dutch confined themselves to depredations upon the marine of Spain and Portugal. In 1630 they attempted again to effect a settlement; and Olinda yielded after a feeble resistance. They were unable, however, to extend their power beyond the limits of the town, until the arrival of Count Maurice of Nassau in 1630. His first step was to introduce a regular government among his countrymen; his second, to send to the African coast one of his officers, who took possession of a Portuguese settlement, and thus secured a supply of slaves. Nassau suffered repulses in several of his expeditions, and particularly in that which he undertook against Bahia. Nevertheless, in the course of four years, the limited period of his government, he succeeded in confirming the Dutch supremacy along the coast of Brazil,

History. from the mouth of the S. Francisco to Maranhão. He expended the revenues of the country, the booty obtained from the Portuguese, and a great part of his private fortune, in fortifying the mouths of rivers, building bridges to facilitate mercantile intercourse, and beautifying and repairing towns. He strictly observed the Dutch policy of tolerating all religions. He promoted the amalgamation of the different races, and sought to conciliate the Portuguese by the confidence he reposed in them. His object was to found a great empire; but this was a project at variance with the wishes of his employers,—an association of merchants, who were dissatisfied because the wealth which they expected to see flowing into their coffers was expended in promoting the permanent interests of a distant country. Count Maurice was recalled in 1644. His successors possessed neither his political nor military talents, and had to contend with more energetic enemies.

In 1640, the revolution which placed the house of Braganza on the throne of Portugal restored Brazil to masters more inclined to promote its interests, and assert its possession, than the Spaniards. It was indeed high time that some exertion should be made. The northern provinces had fallen into the power of Holland; the southern, peopled in a great measure by the hardy descendants of the successive colonists, who had issued on all sides from the central establishment of S. Paulo, had learned, from their habits of unaided and successful enterprise, to court independence. Adventurers had penetrated into those central mountains where the diamond is found. They had ascended the waters of the Paraguay to their sources. They had extended their limits southwards till they reached the Spanish settlements on La Plata. They had reduced to slavery numerous tribes of the natives. They were rich in cattle, and had commenced the discovery of the mines. While yet nominally subject to the crown of Spain, they had not scrupled on more than one occasion to wage war on their own account against the settlements of that country. When, therefore, the inhabitants of S. Paulo saw themselves about to be transferred, as a dependency of Portugal, from one master to another, they conceived the idea of erecting their country into an independent state. But their attempt was frustrated by Amador Bueno de Ribiero, the person they had selected for their king. When the people shouted "Long live King Amador," he cried out "Long live Joam IV.," and took refuge in a convent. The multitude, left without a leader, acquiesced, and this important province was secured to the house of Braganza.

Rio and Santos, although both evinced a desire of independence, followed the example of the Paulistas. Bahia, as capital of the Brazilian states, felt that its ascendancy depended upon the union with Portugal. The government, thus left in quiet possession of the rest of Brazil, had time to concentrate its attention upon the Dutch conquests. The crown of Portugal was, however, much too weak to adopt energetic measures. The tyranny of the successors of Nassau, by alienating the minds of the Portuguese and natives, drove them to revolt, before any steps were taken in the mother country for the re-conquest of its colonies. Joam Ferdinand Vieyra, a native of Madeira, organized the insurrection which broke out in 1645. This insurrection gave birth to one of those wars in which a whole nation, destitute of pecuniary resources, military organization, and skilful leaders, is opposed to a handful of soldiers advantageously posted and well officered. But brute force is unable to contend with scientific valour, whilst the want of numbers prevents the intruders from reaching the enemy they always repulse. The struggle degenerates into unceasing skirmishes and massacres, conducting to no result. Vieyra, who had the sense to see this, repaired to the court of Portugal, and discovering the weakness and poverty of the ex-

History. ecutive, suggested the establishment of a company similar to that which in Holland had proved so successful. His plan, notwithstanding the opposition of the priests, was approved of, and in 1649 the Brazil Company of Portugal sent out its first fleet. The additional impetus communicated by this new engine to the exertions of the Portuguese colonists and their Indian allies, turned the scale against the Dutch; and, after a most sanguinary war, Vieyra was enabled in 1654 to present the keys of Olinda to the royal commander, and to restore to his monarch the undivided empire of Brazil.

From the date of the expulsion of the Dutch down to that of the flight of the house of Braganza from French oppression, Brazil suffered comparatively little from domestic broils or foreign invasion. The approach of foreign traders was prohibited, while the tenths and regalities reserved by the crown drained the country of a great proportion of its wealth. The authority of the governors was despotic in its abuse, but limited in its corrective power; the administration of justice was slovenly in the extreme; the pay of all functionaries, civil, ecclesiastic, and military, was so parsimonious as to render peculation inevitable; and yet, in spite of all these disadvantages, the wealth and happiness of the people continued silently and steadily to increase. The reason was, that they were left in a great measure to themselves, and had an ample field within their own land for the exertion of their industry.

We have already adverted to the important part which the inhabitants of the captaincy of S. Paulo have played in the history of Brazil. The establishment of the Jesuit college had attracted to its neighbourhood a number of settlers from S. Vincente. The Indians of the district were of mild dispositions, and frequent intermarriages took place between them and the Europeans. A race of men sprung from this mixture, native to the soil, hardy and enterprising, wearing but lightly the bonds which attached them to the mother country. The first object of inquiry with the colonists was, whether the land of which they had taken possession were rich in metals. Gold was found, but not in sufficient quantities to reward the labour bestowed in search of it. The Portuguese next devoted their energies to excursions against the more remote Indian tribes, with a view to obtaining slaves. Traces of gold having been observed in the mountain ranges north of S. Paulo, successive bands of adventurers attempted to penetrate the wilderness. The spirit of enterprise was thus nourished and confirmed. From the year 1629 the Paulistas repeatedly attacked the settlements of the Jesuits in Paraguay, although both provinces were nominally subject to the crown of Spain, and carried away numbers of the natives into captivity. Other bands penetrated into Minas, and, still farther northward and westward, into Goyaz and Cujaba, in search of gold.

At first the gold-searchers, like the slave-hunters, undertook temporary expeditions, with the view, doubtless, of returning laden with booty, and settling in their native homes. By degrees, however, as the distance of the newly-discovered mines increased, and establishments for working them became necessary, new colonies were founded. Different associations of adventurers penetrated, in the years 1693, 1694, and 1695, into the district of Minas Geraes, which had been explored by the Paulistas at least twenty years before. In the beginning of the eighteenth century five of its principal settlements were elevated by royal charter to the privileges of *Villas*. In 1720 the district was separated from S. Paulo, of which it had previously been esteemed a dependency, and placed under the control of a governor-general. In 1670 the gold-searchers penetrated into Goyaz; but it was not till the commencement of the next century that, encouraged by the dis-

covery of the mines of Cujaba, in the province of Matto Grosso, a permanent colony was settled there.

The first attempt to regulate by legislative enactments the industry of the miners of Brazil was made as early as 1618 by Philip III. According to his code of regulations, the privileges of the discoverer were that he should have one mine of eighty Portuguese *varas* by forty, and a second allotment of sixty by thirty upon the same vein. A hundred and twenty *varas* were to intervene between the portions. Any adventurer might claim a mine, but he could only have one of the same extent as the discoverer's first portion. No one except the discoverer might have more than one original grant within the distance of a league and a half; but the purchase of another person's allotment within that distance was allowed. Mines might be sought for and worked upon private property because they belonged to the king, but the owner of the land had a right to indemnification. Mining adventurers were entitled to turn their cattle into the lands of the *consello*, and even into private property, without the owner's permission, upon paying the value of the pasturage. No man engaged in mining could be arrested for debt, or have a distress levied upon such capital as he had employed in the work. Mines might only be granted to such persons as possessed the means of peopling and working them. A grant was forfeited if not taken possession of within sixty days. The executive and judicial functions within the mining districts were vested in a provedor and his secretary, those of the fiscal in a treasurer. None of these officials could hold a share in a mine, or trade in its produce, under penalty of loss of office and confiscation of property. The provedor or his secretary measured out the allotments; received and inspected the samples of metal from new mines; registered the grants, with the holder's oath to pay his fifths regularly and faithfully; and decided finally in all disputes to the amount of fifty milrees, with the reservation only of the right of appeal to the *Provedor Mór da Real Fazenda* to any amount. The treasurer received the royal fifths, and superintended the weighing, registering, refining, and stamping of all the gold. The king's share was deposited in a chest under three locks, the keys of which were kept by the provedor, secretary, and treasurer. A yearly account was returned of all the discoveries and produce.

For many years these laws were little more than a dead letter. The Paulistas were wholly engrossed with their expeditions in quest of slaves; the government and the colonists of the other captaincies, with the Dutch and other wars. Some few gipsy-like establishments were scattered thinly throughout the gold country. By degrees the desire of gain induced the more powerful and wealthy colonists to solicit large grants. No attention was paid to the restriction of the number that might be conferred on each individual; and the consequence was, that men of influence monopolized the mines, and were obliged either to sublet them to those they had forestalled, or to leave them unopened. It was found necessary in 1702 to alter the existing laws.

The whole ordinary civil and military authority was vested in the superintendent (*Guarda Mór*). The appointment of the treasurer belonged to this officer. Both were allowed a limited number of deputies. At first the salaries of all these officers were levied upon the miners, but subsequently the privilege of mining was conceded to them in lieu of a salary. No second grant was made to any person until he had worked the first. The allotments were regulated by the number of slaves which the miner employed. Besides its fifths, the crown reserved an allotment, selected after the adventurer had taken his first grant and before he had chosen his second. If an ad-

venturer did not begin to work his ground within forty days, a third part of it, upon information of the lapse, was assigned to the informer, and the other two thirds reverted to the crown. Cattle were allowed to be imported into the mining districts from Bahia, but no persons were allowed to enter except the drovers. They were required to notify their arrival, the number of their cattle, and the prices they obtained. Any person might carry gold-dust from the mines to Bahia to purchase cattle, but not till he had paid his fifths and provided himself with a certificate. These regulations were enforced by strong penalties, in order to prevent frauds upon the revenue. Slaves, and all other goods except cattle, were only allowed to be introduced from Rio, and that either by the way of S. Paulo or Taboate. No idle persons were allowed to remain about the mines; no goldsmith was tolerated there, nor any settler possessed of a slave capable of exercising this craft.

The same infatuated passion for mining speculations which had characterized the Spanish settlers in South America, now began to actuate the Portuguese. Adventurers crowded to the scene of action from all the captaincies; not mere "landless resolute" alone, but men of substance also. Labourers and capital were drained off to the mining districts. The *Engenhos* were either abandoned or left half-cultivated, from the inability of the proprietors to offer for slaves the ruinous prices paid by the adventurers of the mines. Brazil, which had hitherto in a great measure supplied Europe with sugar, sank before the competition of the French and English, who had no mines to distract their attention. Commerce of every kind declined along with this staple commodity. The court endeavoured for a time to counteract this course of enterprise, but in vain.

A new source of wealth for Brazil, had it been properly managed, but, as matters have turned out, merely a new source of injudicious restriction, was now about to be opened up. Some adventurers who had prosecuted the business of gold-washing northwards from Villa de Principe in the captaincy of Minas, made a discovery of diamonds about the year 1710. The value of these minerals was not known till several years after, when an *Ouvridor* of the *Comarca* of Serro Frio, in which they were found, who had seen unpolished diamonds at Goa, ascertained what they were. In 1730 the discovery was announced for the first time to that government, which immediately declared the diamonds regalia. A further search showed that the district was equally rich in other gems. In 1741 its limits were described with greater precision, and the liberty to collect diamonds farmed upon a lease of four years to two influential inhabitants, at the rate of 230,000 rees for every negro, with permission to employ six hundred. At every renewal of the lease a high rent was exacted, and the tenants indemnified themselves by conducting their operations in the most wasteful manner.

While the population of Brazil, and the cultivation of its natural products, continued thus to increase, the moral and intellectual culture of its inhabitants was left in a great measure to chance. There was a hierarchical establishment, but one altogether inadequate to the extent of the territory. There were schools, but "few and far between." The colonists, thinly spread over what appeared an illimitable region, were most of them alike beyond the reach of instruction and of the arm of the law. The restrictions upon the free exercise of industry, introduced with a view to benefit the royal treasury, were little calculated to reconcile men to legal restraints which they scarcely knew in any other form. They grew up, therefore, with those robust and healthy sentiments engendered by the absence of false teachers; but at the same time they became ha-

bituated to a repugnance to legal ordinances, accustomed to give full scope to all their passions, and encouraged by their sense of ascendancy over the Indians to habits of violence and oppression.

From the first moment of their landing in Brazil, the Jesuits had constituted themselves the protectors of the oppressed natives. But they were strenuously opposed by the interested colonists, and by hedge priests, who lent their countenance to the infamous traffic in human beings, as they would have pandered to any other vice, in order to retain their ascendancy over the minds of the settlers. The Jesuits were not however easily dismayed, and, by dint of the most persevering exertions, they at last elicited from government an explicit confirmation of the freedom of the natives. The next step of these venerable fathers was to collect their red children, as in all their other missions, into *aldeas*, over which officials of their order exercised both spiritual and temporal authority. Their intentions were pious and noble, but their plan was erroneous. They attempted to teach the most recondite dogmas of the Christian faith, before either the hearts or heads of their pupils were sufficiently awakened to comprehend them. They taught observance to the rules of external decorum, without inculcating those more essential principles which are independent of all form. By depriving the Indians of the power of managing their own affairs, they effectually stifled within them the germs of human thought and action. It is only by free action, right or wrong, and the consciousness of its consequences, that man can be awakened into intellectual life. The Indian of the *aldeas* was little better than a puppet, and, when separated from his tutors, he soon sunk back into hopeless and irreclaimable barbarism.

The persecution of the Indians was yet more efficaciously put a stop to by the sacrifice of an equally innocent and yet more injured race. The Portuguese establishments on the coast of Africa have ever been more extensive, and their slave dealings better organized, than those of any other nation. By this means an immense number of negroes were annually imported into Brazil, and being found more active and servicable as labourers than the native tribes, the latter were in a great measure left to enjoy their savage independence. The Jesuits, like Las Casas, professed a limited philanthropy, and, satisfied with securing their own clients, winked at the oppression of the blacks.

The Portuguese government, under the administration of Carvalho afterwards Marquis of Pombal, attempted to extend to Brazil the effects of that bold spirit of innovation which directed all his actions. The motives which instigate man's conduct are of such a mingled nature, and so inextricably intertwined, that the question in how far this minister was actuated in his first step by regard to the public good, and how far by private pique, is of no easy solution. Luckily, it is of little importance, in a sketch of a nation's history, where individuals tell merely as counters.

Carvalho had experienced great resistance to his plans of reform at home from the Jesuits; and his brother, when appointed governor of Maranhão, experienced a resistance no less strenuous on their part to some measures of his government. This was enough to determine the proud minister to lessen the power of the order. With his sanction, the Jesuits and other regulars were deprived of all temporal authority over their *aldeas* in the state of Maranhão and Para. These, being twenty-eight in number, were converted by the edict of the governor into nine townlets, eighteen towns, and one city. The towns were to be governed by *juizes ordinarios*, to fill which offices a preference was given to Indians. The *aldeas* independent of towns were to be governed by their respective chiefs.

History. The lands adjacent to the towns and hamlets were divided among the Indians, and declared heritable property.

To these regulations of his brother, the minister super-added some enactments intended to supply the loss of the Jesuits as teachers. The task of religious instruction was delegated to the bishop. Till such time as the Indians should be sufficiently advanced in civilization to manage their own affairs, a director was appointed to reside in each settlement; a man of integrity and zeal, and conversant with the native tongues. He possessed no coercive jurisdiction, but, when he observed remissness on the part of the native authorities in the administration of the laws, might complain to the governor. He was expected to explain to the Indians the advantages of industry and sobriety, to instruct them in the simpler arts and manufactures, and to recommend the adoption of the amenities of civilized life. Above all, these functionaries were directed to combat the prejudice, that there existed a natural inferiority in the Indian character, and to promote, as far as in them lay, intermarriages between the white and red races. As a reward for the directors, they were to have a sixth part of all that the Indians reared, excepting what was specially appropriated for their own consumption.

These ordinances, originally promulgated for Maranhão and Para, were ratified in Lisbon, and extended to the whole of Brazil. But the good which they might have done was neutralized in a great measure by some compulsory services still left binding upon the Indians, and by listlessness on the part of the white inhabitants in carrying them into effect. No good understanding could subsist between an ambitious order and the minister who had so openly braved them. Carvalho felt his new arrangements insecure as long as a Jesuit remained in Brazil. First of all, he sought to render the order suspected of being accessory to some partial revolts among the Indian troops on the Rio Negro. But it was the confession of one of the leaders of the conspiracy against the life of the king of Portugal, when put to the torture, that some Jesuits were implicated in the undertaking, that finally delivered them into his hands. In 1760 they were expelled from Brazil, under circumstances of the most unmitigated cruelty.

Pombal's next measure attracted more attention than his plans for the improvement of the Indians. The Brazilian Company, founded by Vieira, which so materially contributed to preserve its South American possessions to Portugal, had been abolished, in 1721, by Joam V. Such instruments, however, were calculated to win the confidence of a bold spirit like that of Pombal. In 1755 he established a chartered company, with a capital of 1,200,000 crusados, in 1200 shares, to trade exclusively with Maranhão and Para. In 1759 a similar company was chartered for Paraíba and Pernambuco. Remonstrances were made on the part of the Board of Public Good, and the British factory at Lisbon; but the members of the former body were punished, and those of the latter were disregarded. Encouraged by success, the minister established an exclusive company for the whale fishery, and bestowed upon it the monopoly of furnishing Brazil with salt. This company had its head-quarters in the island of S. Catthaina. Some time after these arrangements, an extension of the facility of intercourse was granted, and Portuguese subjects, instead of being restricted to the annual fleets, were allowed to trade in single ships to Bahia and the Rio.

The arrangements of Pombal extended also to the interior of the country. The claims of the original donatories in the respective captaincies were indefinite and oppressive in the highest degree. Other ministers had from time to time bought up some of these rights; Carvalho extinguished them at once, indemnifying the holders. With all his power, however, he durst not interfere in be-

half of such new Christians (converted Jews) as were accused of adhering in private to their ancestral faith; but he prohibited, under strict penalties, light and malicious denunciations. He strengthened and enforced the regulations in the mining districts. Observing the profuse mode in which the treasures of the diamond district were lavished, he moved the king to take the management of it into his own hands. In 1772 an ordinance was issued, in which Pombal, as prime minister, reserved to himself the management of this district. The details of business were discharged by three directors in Lisbon, and three administrators in Brazil. At the head of the latter was placed an intendant-general, who, as the representative of majesty, exercised an unlimited power within his jurisdiction. He controlled the working of the diamond mines; he stood at the head of the judicial and police establishments; and he was authorized to punish every inhabitant convicted of having jewels in his possession with banishment and confiscation of goods, and even upon mere suspicion to order any individual to quit the district.

The policy of many of Pombal's measures is more than questionable. His encouragement of monopolies, and his preference of the interests of the crown to those of the state, as evinced in the regulations of the mining and diamond districts, do not admit of defence. But the extirpation of the Jesuits, and the admission of all races to equal rights in the eye of the law—the abolition of feudal privileges, and of certain restrictions upon commerce, with the livelier spirit which he knew how to infuse even into his monopolies—powerfully co-operated towards the development of the capabilities of Brazil. The spirit of improvement must have been already awake in the bosoms of the people, otherwise even his legislative energies must have been expended in vain. Still the merit abides with him of having firmly organized the powers of the land, and marshalled their way. And yet when, upon the death of his king and patron in 1777, court intrigue forced him from his high station, his successor was lauded to the skies for concluding a treaty of limits, in which Pombal's chivalrous bravery had rendered Spain glad to acquiesce, whilst he who had done so much for his country's institutions was reviled on all hands. The first epoch of Brazilian constitutional history is the struggle of the isolated captaincies to establish themselves on the coast. The second is their union under one common head, and under established laws, by the appointment of a governor-general. The third is the amended organization of the extensive empire by Pombal. The fourth, to which we are now about to turn, has just been accomplished, leaving Brazil to start free and energetic on a new and untried career.

The thirty years which succeed Pombal's retirement from active life present scarcely any marked feature for the historian to depict. The mining districts continued to be enlarged, especially in the direction of Matto Grosso. The companies of Maranhão and Pernambuco were abolished, but the impulse which they had given to national industry remained. Cotton, the growth of which they had promoted at Maranhão, was introduced into Pernambuco, and cultivated so successfully as to become in a short time the main article of export. Roads were opened throughout the country, to facilitate internal intercourse. Removed from all communication with the rest of the world, except through the mother country, Brazil remained unaffected by the first thirteen years of the great revolutionary war, except in as far as regard some slight disputes respecting the limits of French and Portuguese Guiana. Indirectly, however, even this isolated country had participated in the impulsion which had passed, like electricity along the links of a chain, from nation to nation.

With time and industry came wealth; with wealth came the feeling of importance, followed by an investigating spirit; and then succeeded, under every disadvantage, bold inquiry and assertion of rights. Latterly too the exclusion of foreigners had not been so strictly enforced. The ports of Brazil were still closed against foreign traders; but the entrance of men of war, and such merchant ships as could find no other harbours to refit in, gradually introduced a tolerated freedom of intercourse.

The prince regent of Portugal, afterwards Joam VI., driven from the mother country by the invasion of the French, landed at Bahia on the 21st of January 1808. The royal family was received with enthusiasm; but it was at that time in search of a secure asylum from a power which the monarchs of the continent of Europe began to believe reached everywhere; and Bahia, easily assailed from the sea, might at any time, by a very small land force, be cut off from all supplies by land. The harbour of Rio, on the other hand, is easily defended, and has at all times an easy communication with the interior. Towards Rio, therefore, the royal fugitives shaped their way, and arrived there on the 7th of March.

The first care of the regent was to introduce into Brazil the same state arrangements which had existed in Portugal. In the course of the year 1808 he organized the *dezembargo do paço* (council of state), *conselho da justiça* (ministerial council of justice), *conselho da fazenda* (ministerial council of justice), *meza da consciência* (consistorial tribunal). The *relação* (court of appeal) of Rio Janeiro was erected into a *supplicação* (supreme court of appeal) for the whole country; a royal treasury, mint, and register were erected; a supreme board of police for the whole of Brazil was instituted; the boundaries of the captaincies were ascertained with greater precision; the powers of the provincial governors, and the jurisdiction of the provincial courts, were defined with greater strictness; and the collection of the royal tenths was subjected to a revised system.

This increased energy and precision of the organization of the executive would of itself have conferred an inestimable benefit upon the country; but the arrival of the royal family brought yet more important advantages in its train. On the 18th of February 1808 a *carta regia* threw open to foreigners a free commercial intercourse with all the harbours of Brazil. On the 12th of October the same year the regent sanctioned the statutes of a bank which had, some years before, been established at Rio, and conferred upon it, with extensive privileges, the title of *Banca do Brasil*. This institution, in addition to its private mercantile functions, discharged those of farming many of the regalia. It was also in the practice of advancing large sums to the state, sometimes in consideration of valuable deposits, sometimes upon the assignment of taxes not yet due. Foreign merchants caused more than one run to be made upon the bank, with a view to try its stability; but its connection with the mint enabling it to meet every emergency, it maintained a high degree of credit, at least with the subjects of the state of Brazil. The increased activity which a multitude of new customers, and an increased circulating medium, imparted to the trade of Rio, added a new stimulus to the industry of the whole nation. In a short time the government was enabled to reduce many of its impositions one half. Immense numbers of English artisans and ship-builders, Swedish iron-founders, German engineers, and French artists and manufacturers, sought fortunes in the new land of promise, and diffused, both by example and precept, industry and ingenuity throughout the kingdom.

In the beginning of 1809 French Guiana was taken possession of by the Brazilian troops, and the territories of

the state thus extended on the north to the limits they still maintain.

Towards the end of the year 1811 a royal decree assigned 120,000 crusadoes per annum, to be taken from the customs of Bahia, Pernambuco, and Maranhão, for forty years, to the Portuguese who had suffered during the French war. This most unjust appropriation of the state revenue naturally excited discontent in these powerful provinces. It happened also that the salaries of many officers, both civil and military, remained at this time unpaid; a circumstance which had been made in more than one district a pretext for exactions. Some disputes had taken place between the Brazilians and English respecting the slave-trade; and the former, already disposed to suspect their own government, viewed with a jealous eye the British establishment at Rio. In order to avert or allay the gathering storm, an edict was issued on the 16th of December 1815, raising Brazil to the dignity of an independent kingdom, and placing it on an equal footing with Portugal and the Algarves. The national pride was flattered, and for some time nothing else was heard of but addresses of thanks and congratulations, with feasts and rejoicing in every district.

In 1817 the discontents of the northern provinces, which had for a while been hushed, broke out into open insurrection in Pernambuco. The people of Recife entertained some democratical notions, which might, perhaps, by a curious observer, be traced to the period of the Dutch government. They remembered, with no small degree of pride, that it was mainly their own endeavours that had driven out these foreigners; they were jealous of Rio's monopoly of the advantages of a royal residence; but, above all, they were averse to the payment of taxes for the support of a luxurious court. A regular plan of insurrection was formed; troops were raised and disciplined; and fortifications were begun in one or two places. By the loyalty of the neighbouring provinces, and the promptitude of the royal troops, this premature revolt was easily suppressed; but the cruel punishments of the leaders served to diffuse the spirit of disaffection more widely throughout the north. The war in which Brazil had been involved towards the frontiers of Buenos Ayres, by obliging the government to call out the *milicias* of S. Paulo, had, by involving these hardy countrymen in a quarrel respecting the merits of which they knew little and cared less, excited among them no small degree of discontent.

In November 1820 the news of the revolution in Portugal reached Brazil. A kindred spirit spread at once throughout all the provinces. Para took the lead. On the first day of the year 1821, the infantry declared for the constitution; the cavalry and artillery joined them; a provisional government was appointed; and all this was done in the name of the king, and without bloodshed. On the 10th of February the troops rose in Bahia. A few lives were lost; but ultimately, both troops and people, in the presence of the governor, solemnly declared their adherence to the constitution which should be formed by the Cortes. A governing junta was appointed, which speedily received addresses of adhesion from all the towns and villages in the neighbourhood. The ferment was perhaps greater in Rio than anywhere else, from the more determined opposition offered to all constitutional projects by the king and the court party. On the 18th of February, however, a conviction of the folly of resistance induced the king to recognise a junta of his Brazilian subjects, appointed to take into consideration such parts of the constitution as might be applicable to Brazil. A mutual distrust continued to exist, which might have led to the most fatal consequences but for the promptitude of the prince Dom Pedro. In the morning of the 26th, every thing threatened immediate bloodshed, when he presented him-

History.

History. self to the citizens with a list of a new ministry, and voluntarily took the oath to the new constitution. His conduct on this occasion afterwards received the express sanction of the king, who resolved, however, to return to Lisbon; a resolution which he carried into effect by sailing on the 24th of March ensuing.

Before going on board, he appointed Dom Pedro regent in his absence. He addressed the troops, recommending to them fidelity to the crown and the constitution, and promising an increase of pay to all. This was a cruel mockery of the regent; for he had left nothing in the treasury wherewith that prince could fulfil the promise. Nor was this the full extent of the evil. Immense sums were carried out of the country by the Portuguese who followed the king to Lisbon. The well-grounded belief that the coffers of the bank had been emptied by the king, gave a shock to its credit which it has not yet recovered. A large amount of specie had been taken up for government bills, on the treasures of Pernambuco, Bahia, and Maranhão, which had disclaimed the superiority of the government at Rio. The prince was thus left, with an empty treasury, to rule over a people which felt itself beggared by the dishonesty of government, at a moment when, even without this conviction, sufficient seeds of civil commotion were everywhere scattered abroad.

Dom Pedro acted in this trying emergency, in conjunction with the junta of Rio, like a man of sense and spirit. He remitted some of the most oppressive imposts upon the trade of the interior, particularly the duties on salt. Something was done towards improving the condition of the schools, hospitals, and barracks. Books were allowed to be imported duty free. The junta published an exhortation to tranquillity, obedience, and a patient waiting till the result of the deliberations of the Cortes, now joined by their own deputies, should be known. At the same time they invited all persons to send in statistical notices and plans for improvements.

The circumstance, however, which contributed perhaps more than any other to strengthen Dom Pedro's hands, and uphold his power, was one which wore at first a threatening aspect. At S. Paulo, the regiment of caçadores, discontented at not receiving the promised augmentation of pay, took up arms in a tumultuous manner on the 3d of June, and threatened not to lay them down again until they received it. They were with difficulty restrained from proceeding to extremities, owing to the presence of mind exhibited by their captain. A strong excitement, however, continued to agitate, not only the troops, but the people. The magistrates and principal inhabitants took advantage of the occasion furnished by the assembly of the militia, on account of a festival on the 21st. They were kept together, and assembled in the great square before the town-house. The great bell of the Camara was tolled, and when the people had assembled, the cry was raised of "Viva el Re, Viva el Constituição, Viva o Principe Regente," and a provisional junta demanded. This request was re-echoed by the crowd, and complied with by the magistrates. From that moment all remained quiet in the city, and the most important province of Brazil declared for the prince.

The remainder of the year was spent in organising provisional juntas in the different capitals. On the 19th of September an edict was addressed to all these bodies, enjoining them to communicate directly with the Cortes at Lisbon. It was fondly hoped that the Cortes would admit Brazil to all the privileges of an integral part of the nation, with independent courts, civil and criminal. The Cortes were, however, too much afraid of losing a rich colonial dependency, to entertain such a thought. They passed decrees for the election of separate governments

History. in every province of the Brazils; and for the appointment of a military commander in each, who should be independent of the provincial government, and accountable only to the Cortes for his conduct. The prince was ordered to return to Lisbon as soon as these governments were established. These decrees reached Rio Janeiro before the end of December 1821, and excited universal indignation.

The junta of S. Paulo were the first to move. On the 24th of December they applied to the regent, requesting him to remain among them. The prince answered that he had transmitted their address to the king. On the 7th of January 1822, the Camara of Rio and the wealthiest inhabitants addressed his royal highness on the danger to be apprehended in the event of his obeying the Cortes. With apparent hesitation he promised to delay his departure till the ultimatum of the Cortes should arrive. A movement was threatened on the part of the Portuguese troops in Rio; but prompt measures being taken with them, they were obliged to embark for Europe. Not long after, the junta and inhabitants of Pernambuco obliged the Portuguese troops stationed in that city to embark for Lisbon. Madeira de Mello continued to hold Bahia with 1500 European troops and some militia for Portugal; and Monte Video was kept possession of in the king's name by General Lecor. All the rest of Brazil was in the hands of the independents. Thus circumstanced, Dom Pedro accepted the title of prince regent and perpetual defender of the Brazils, and convoked a general assembly of the states, consisting of one hundred deputies, nominated by parochial electors chosen by the people. The avowed purpose of collecting such a body was, that it might deliberate in public session upon the precise terms on which Brazil was to remain united to Portugal, examine whether the constitution of Lisbon were adapted to Brazil, and suggest necessary emendations. It was also provided, that as soon as the constitution should be agreed on, the council of representatives should assume legislative functions, determine the seat of Brazilian sovereignty, and communicate the resolutions of Brazil to the Cortes of Portugal. On the meeting of the council, the prince informed them of the anxiety manifested in all quarters for the convocation of a general constitutional legislative assembly; and when they declared their acquiescence, a decree was issued to that effect. The independence of Brazil was proclaimed on the 1st of August; and on the 12th of October, his birth-day, Dom Pedro was installed constitutional emperor and perpetual defender of Brazil.

The Cortes having intimated sufficiently their resolution to retain Brazil, two decrees were issued by the emperor on the 11th of December; the first laying an embargo on all vessels bound to the Portuguese territories in Europe; the other sequestering all goods belonging to Portuguese subjects, with one or two trifling exceptions. On the 11th of January 1823, another decree was issued, encouraging Brazilian subjects to take out letters of marque against Portugal. Meanwhile Madeira, who had been reinforced from Portugal, began to infest the neighbourhood of Bahia with hostile attacks. But on the 21st of March, Lord Cochrane hoisted his flag on board the Pedro Primeiro. On the 2d of July, Bahia surrendered, and the Portuguese fleet put to sea, but was followed and destroyed by the Brazilian admiral. In the course of the year Monte Video surrendered, and the independence of Brazil was established, although not recognized by the mother country till near the close of 1825.

The interior of the new empire was far from presenting an equally satisfactory picture. The proclamation of the emperor had been received with hearty good will by all, as the readiest step to independence. With regard, how-

ever, to the organization of the state, there prevailed a marked difference of opinion. The republican party was very strong, particularly in the northern and central provinces. There was a yet more numerous body which ardently desired a constitutional monarchy. But there were also a few, formidable chiefly as including among their number some of the most practised intriguers of the court, and several military leaders, whose views favoured a despotic government. A false step on the part of the ministers, who were firm constitutionalists, at the first opening of congress, and the inopportune illness of the emperor, threw such a power into the hands of the democratic party, that a new ministry was chosen. The assembly next proceeded to discuss the propriety of conceding to the emperor an absolute veto. It was resolved by a considerable majority that such a veto was inexpedient. The emperor, however, declared his resolution not to acquiesce in this determination. The assembly prepared some obnoxious decrees in order to put his resolution to the test, and he began to caress the military. The strong language of the journals on the one hand, and the violent proceedings of some European officers on the other, brought the matter to a speedy termination. On the 12th of November, while the assembly was sitting, news arrived that two columns of military were approaching the city; and immediately afterwards a military officer brought an imperial rescript dissolving the congress. This body quietly dissolved, but several of the leading members of the constitutional and republican parties were immediately arrested.

Dom Pedro found himself in an awkward predicament. The annual revenue only covered two thirds of the expenditure. The local revenues of all the different provinces were likewise inadequate to cover the local expenditure. Attempts had been made to supply the deficiencies by forced loans and donations, and even by sequestrations; means which are soon exhausted, and always create hostility. Several of the ministers resigned in disgust at the emperor's proceedings. It was with difficulty that others were found to supply their places, and even they soon followed the example of their predecessors. Disturbances broke out in several of the provinces, and were suppressed with the greatest difficulty. Pedro soon gave way to the storm, and promulgated on the 11th of December the project of a constitution, which for a time pacified the country.

The history of Brazil from this period down to the moment of Dom Pedro's abdication is only interesting as displaying the growing intelligence and business talents of her statesmen, and the incapacity of her emperor. He plunged into wars without forethought, and retreated from them without having attained his object. He took no one decided step towards arranging the finances or consolidating the institutions of the country. Without comprehending or respecting the rights of his subjects, he aimed at being popular; destitute of military talents, he coveted military glory; no politician, he aspired to despotic power. His conduct was vacillating, his actions were inconsequential and ineffective. The safety of the empire demanded his removal on the ground of incompetence. What may be the future fate of Brazil it is impossible to predict with certainty. The predilections of a strong party in favour of republican institutions, an infant prince, and the absence of a privileged aristocracy, are strong indications.

II. *Physical Geography, &c.*—Brazil extends, in its greatest length, from the sources of the Rio Branco, near the fifth degree of north latitude, to the sources of the Ybicui, near the thirty-first degree of south latitude. In its utmost breadth it extends from Cape St Augustine, in the thirty-fifth degree of west longitude, computing from

Greenwich, to the river Javary, about the seventy-third. From the embouchure of the Rio Grande in the south, to that of the Wiapoc, between the fourth and fifth degrees of north latitude, the Atlantic Ocean forms the eastern boundary of Brazil. This portion of its outline is of an irregular crescent form, extending in a curved line from the fifty-third degree of west longitude, at the thirty-third degree of south latitude, to the thirty-fifth, betwixt the ninth and tenth; and then retrograding more abruptly to the fifty-second degree of west longitude, between the fourth and fifth degrees of north latitude. The inland frontier of Brazil may be thus traced:—First, turning to the north, we start from that point in the Javary which crosses obliquely the seventy-third degree of west longitude; we descend the stream to its junction with the Amazons; follow the downward course of that river to the point where it receives the waters of the Yupura; ascend the latter till we reach the degree of longitude in which the Javary and Amazons mingle their waters; from that point cross the country to the Fall of Corocobi on the Rio Negro; and thence pursue the line of the summits of the Cordillera, dividing the waters of the Essequibo from the tributaries of the Amazons, till we arrive at the sources of the Wiapoc, which we descend till we reach the ocean. Returning to our starting place, we follow a line extending due east from the Javary to a point exactly mid-way between the spot at which the conjoined waters of the Guapore and Mamore receive the name of Madeira, and that stream's confluence with the Amazons; ascend the Madeira and Guapore to its source; cross the mountains by a line running north and south; strike the waters of the Paraguay at the mouth of the Juaru; and descend to the station of Nova Coimbra. From this point the boundary line pursues a zig-zag course, determined by the currents of a number of minor streams, which it alternately ascends and descends, keeping in the main the direction of south-south-east until it reach the ocean at the neutral ground of Minio Merin.

The territory comprised within these boundaries may be roughly estimated at little less than two millions of square miles. A considerable portion has never yet been explored; and respecting the whole our information is often vague and unsatisfactory. Even the line of coast has not been laid down with any degree of certainty; and the Portuguese maps are in this respect utterly unworthy of attention. They have been republished for centuries without revision or amendment; and we have no information respecting the observations and calculations upon which they were based. The English charts are better, being the accumulated experience of practical seamen, who had a deep stake in rendering them as accurate as possible. In general, however, they are anonymous; and the well-known difficulty of determining the latitude and longitude by observations made on board of ship alone still more diminishes our confidence in them. Some French charts lately published, bearing to be the results of a special exploratory expedition, have only tended to increase our uncertainty, by their wide deviation from all former authorities. When we turn to the interior of the land, matters are still worse. Distances and localities are in general assumed upon the authority of the conjectures of travellers provided with no more accurate instrument than a compass, or of the rude estimates of the inhabitants of European or Indian descent; and there are numerous districts regarding which we are entirely destitute of even these meagre and inaccurate sources of information.

The natural conformation points out two great divisions Surface of the territory of Brazil; the valley of the Amazons to the north, and the hill country to the south. The physical structure of each of these districts is necessarily depen-

phy.

Rivers.

dent upon the other, and their respective characters can only be properly comprehended by mutual reference. It will better enable us, however, to comprehend both, if we at first view them apart: and in attempting a sketch of each, we shall commence with that of which less is yet known than of the other, but which is in all probability doomed one day to make a prominent figure in history; we mean the valley of the Amazons.

The immense course of the river Amazons, from Tabatinga, where it enters the confines of Brazil, to the ocean, deducting its windings, extends, when we pursue the course of the main channel, to $401\frac{1}{2}$ leagues, of twenty to a degree, or, when we deflect to the estuary of Para, separated from the former by the island Marajó, or St John's, to $506\frac{1}{2}$. The breadth of the stream at Tabatinga is given by Condamine as between 800 or 900 toises; at Obydos, 106 leagues from the sea, and where the tide ceases to be perceived, Martius assigns to it the breadth of 869 fathoms. The greatest breadth of the river is about six leagues. Tabatinga is elevated above the level of the ocean 634 Parisian feet. The direction of the river is almost parallel with the equator, from which its mean distance may be between one and two degrees. Its principal confluent during this portion of its course are, from the south, the Tocantins flowing into the estuary of Para, the Xingu, the Tapajoz, and the Madeira; from the north, the Rio Negro and the Yapura.

The Tocantins joins the estuary of Para at the distance of thirty-three leagues from the ocean, and at an elevation of 189 Parisian feet above its level. The Xingu falls into the Amazons 45 leagues from its northern or main junction with the ocean, and 347 feet above its level, at which place it is about a league in breadth. The Tapajoz joins the Amazons ninety-two leagues above the main entrance into the ocean, at an elevation of 404 feet above the level of the sea. No observation is recorded of the exact elevation of the point where the Madeira mingles its waters with those of the Amazons, but Spix estimates it at 509 feet. Its distance from the ocean in a direct line is nearly 180 leagues. Its breadth varies, according to the season, from 930 to 1000 fathoms; its depth in the middle of the stream from twenty-three to twenty-seven fathoms, and at the shore from five to ten.

The courses of these four rivers are nearly parallel, flowing in the direction of south-south-east. During the greater part of their course they have little perceptible fall. A kind of natural terrace, however, extending in the direction of south-west and north-east, intersects the course of all at an oblique angle. This sinking of the land forms in each a system of cataracts, dividing their course into an upper and lower valley; and the same phenomenon is visible in all the parallel minor streams which flow between them. On the Tocantins these cataracts occur a little to the northward of the fourth degree of south latitude; on the Xingu, to the southward of this line; on the Tapajoz they occur rather to the southward of the fifth degree; and on the Madeira also to the southward of the eighth. The course of the Madeira from its source to the cataracts is 172 leagues, thence to the plain 325. The bed of its waters above the cataracts is estimated at 150 feet higher than that below. The character of the ground remains much the same, being low, and intersected by innumerable canals and lakes; its principal eastern branch only, which inclines towards a serra, retains any characteristics of a clear mountain stream. The extent of the Tocantins, from the lowest cataract to its embouchure, is about sixty leagues in a direct line. The high land even approaches somewhat nearer to the Amazons along the eastern bank of this tributary. The main branch of the Tocantins, that to the east, descends from the high mountain lands of the

north. The more westerly feeders seem to drain off the accumulated waters of high-lying morasses, similar to those which swell the stream of the Madeira. Of the Xingu and Tapajoz above the cataracts almost nothing is known; but every circumstance connected with them seems to indicate a *terrain*, similar to that which gives birth to the Madeira and the western tributaries of the Tocantins.

We now turn to the north side of the great basin of the Amazons. The Rio Negro joins the main stream at a distance of 197 leagues from the ocean, and at an elevation of 522 feet above its level. The principal mouth of the Yapura is at the distance of 326 leagues from the ocean, and the elevation of 571 feet. The course of these two rivers is nearly parallel, both flowing from west-north-west to east-south-east. The Yapura enters the Brazilian territory immediately beneath the Falls of Cupati. The river flows from these falls to the Amazons, an extent of 100 leagues in a direct line, and its fall is estimated at 200 feet. The Rio Negro extends from the frontier fort of S. Carlos, near the junction of the Cassiquari, which carries a portion of the waters of the Orinoco to the Amazons, to Barra do Rio Negro, a distance of at least 200 leagues. The elevation of the last-mentioned situation above the level of the sea is, as we have already mentioned, 522 feet; while that of S. Carlos is 762. The alternate widening and narrowing of the river, as well as its very unequal depth and varying rapidity, lead naturally to the conclusion that it has been formed in the course of ages by the progressive widening of their connecting streams, giving to a system of inland lakes the appearance of one continuous river. The Rio Negro joins the Amazons at an angle so obtuse as to admit of our viewing them in a general way as one continuous line, 397 leagues in length, cutting the equator obliquely towards its western extremity. Parallel to this, at a mean distance of four degrees of longitude, extend the various serras composing the mountain land of Upper Guiana. The flat land which everywhere forms the banks of the lower Amazons and its confluent extends to the base of these hills, which rise at once with considerable abruptness. This territory is intersected by a number of streams of minor consequence, falling partly into the Rio Negro and partly into the Amazons. The most important of these, the Rio Brancas, flows from north to south, and joins the former.

In describing the superficies of the valley of the Amazons, we have found it most expedient to stretch out the streams as the veins upon which the reader was to fancy the superficies of the leaf extended. In turning to the southern and mountainous district of Brazil it will be necessary to call the mountain ranges to our assistance.

If the reader, then, will cast his eye upon a good map of Brazil, he will find, in latitude 19° to 21° south, the mountains of Itacolumi, 5710 English feet above the level of the sea, and of Itambi, 6900. These, and their connecting range, may be considered as the nucleus of the mountain formation of Brazil. Towards the north, and parallel to the coast, extends the Serra do Mar, under the varying names of the Serra dos Esmeraldos, Serra do Frios, &c. Towards the south-west a similar, or rather the same chain (the Mantiqueira), stretches, throwing out spurs on either side, till it gradually subsides into the high plain on the eastern side of the Paranna, near its mouth. By means of the Serra dos Vertentes the Itacolumi connects with the system known under the names of Montes Pyreneos, Serra do Sijada, and Serra do Anambuhy, extending in the direction of west-south-west to the banks of the Paraguay, a little above where it receives the waters of the Paranna. That part of the latter chain termed Montes Pyreneos extends towards the north to the sources of the Tocantins. An important arm of this

latter, the Itiapamba, but of which little is yet known, runs out to the north-east, and loses itself in the northern seaboard provinces of Brazil. To the west extends the Serra Geral. To the south and the west, in the provinces of S. Paulo and Matto Grosso, these mountains attain an elevation considerably above the level of a high and extensive inland plain. To the north-east, in Minas Geraes and Goyaz, they rise from an infinitely lower level above the sea. Nevertheless, while those mountains which have for their base the high inland plains of Piratininga and Matto Grosso seldom attain a higher elevation than 1900 Parisian feet above the sea, the average height of the Montes Pyreneos is 3900. From the Serra dos Vertentes, in latitude twenty degrees south, flow the streams which combine to form the Rio Francisco; at first in the direction of north, afterwards curving towards the east, till it reach the ocean in latitude eleven degrees south. On the southern declivity of the same Serra arise the highest sources of the Paranna. They flow at first in the direction of due west, receiving numerous tributaries to the north from the Montes Pyreneos, &c., to the south from the Serra do Mantiqueira. Having reached the base of the Serra do Sijada, in longitude fifty-three degrees west, and latitude twenty degrees south, the Paranna assumes a south-easterly direction, and, still receiving numerous tributaries from the two mountain ridges which bound its valley, joins the Paraguay in latitude twenty-seven south, and longitude fifty-eight west. From the south-eastern declivity of the Mantiqueira descends the Uruguay to the estuary of La Plata. From the eastern side of the same ridge, and its northern continuation the Serra do Mar, a number of minor streams flow into the ocean. To the northward of the Serra dos Vertentes, the western streams of the Serra do Mar and the eastern of the Serra do Sijada flow into the Rio Francisco. From the southern declivity of the Serra Geral, and from the western side of the Serra do Anambaty, flow the confluent of the Paraguay. From the northern side of the Serra Geral, and from the central and eastern branches of the Montes Pyreneos, descend the four great tributaries of the Amazons, which join that inland ocean from the south, and the streams that intersect the coast of Brazil between Para and the mouth of the Rio Francisco.

The great constituent of all the mountain ranges of Brazil is granite; the maritime ridge seems exclusively composed of it. The soil on the shore consists of clay, covered in many places with a rich mould, resting on a bed of granite, mixed with amphibole, felspar, quartz, and mica. In the high inland plains of Piratininga we find on the surface a red vegetable earth impregnated with oxide of iron; beneath this a layer of fine argil, intersected with veins of sand; and, thirdly, an alluvial stratum containing a great quantity of iron, resting on mouldering granite, quartz, and mica. A mass of solid granite supports the whole. Between Rio Janeiro and Villa Rica the soil consists of a strong clay, and the rocks are composed of granite. The mountains in Minas Geraes are composed of ferruginous quartz, granite, or argillaceous schistus. Beds of limestone have been found near Sorocabá, near Sabara in Minas Geraes, and in the gold mines near S. Rita. The immense central plateau of Matto Grosso has never been sufficiently explored; but from the nature of its mineral products there is every reason to believe that the granitic formation prevails there also. The Itiapamba, the great chain on the northern coast, consists chiefly of granite. The northern coast from Maranhão to Olinda is bounded by a reef of coral, in many places resembling an artificial mole. It is employed by the inhabitants in building their houses. The valley of the Amazons has been so little explored, and its impen-

trable woods and luxuriant vegetation throw so many difficulties in the way of the geologist, that a long time must yet elapse ere we can hope for satisfactory intelligence. As far as the observations of Spix and Martius extend, its geognostical relations are sufficiently simple. All along the banks of the main stream, and of its tributaries, as long as they continue in the plain, only two mountain rocks are discovered,—the variegated and the green sandstone. Sometimes the sandstone appears in the form of a composite breccia, containing iron; sometimes of a fine-grained crumbling red; sometimes of a hard white stone; but the former is the more prevalent. Beds of marl, clays of different colours, and porcelain clay, occur frequently. On the Tapajoz gypsum occurs in one place. To the south this sandstone formation is bounded by the granitic ridges of the Itiapamba, Montes Pyreneos, and Serra Geral. On the northern ridge of the first-mentioned chain a transition limestone is interposed between the granite and the sandstone. To the north the sandstone is bounded by the gneiss and granite of the Parimé range; to the westward, on the rivers Negro and Yapura, a quartz rock of slaty structure is the basis on which it rests. The western and south-western limits of the sandstone of the Amazons are imperfectly known.

The metallic and mineral products which occur in the geological formations above described are various. Iron is found in vast quantities in the high plains of S. Paulo and in Minas Geraes. Entire hills are composed of brown ironstone and magnetic ironstone. In the latter province a secondary ironstone fills whole valleys, and spreads like a mantle over many of the hills. In Goyaz and Matto Grosso whole districts are covered with formations rich in iron ore. Gold is next, in the extent of country through which it occurs, to iron. It is found in grains intermingled with the latter metal almost wherever it is worked. The chief scene of the exertions of gold-miners has hitherto been in the district of Minas Geraes, among the central mountains, and at the sources of the Paraguay. It is certain, however, that the gold country extends to S. Paulo on the south, and to the mountains among which the Tocantins arises on the north. The soil where the gold is found is ferruginous and deep in many places, resting on rocks of gneiss and granite. The gold rests on a stratum of *cascalho* or gravel, incumbent on the solid rock. It occurs sometimes in grains, sometimes in crystals, and occasionally in large masses. Lead and zinc have been found on the banks of the Rio Abaité, a tributary of the Rio Francisco; chrome and manganese in Parãopeba; platina in other rivers; quicksilver, arsenic, bismuth, and antimony, in the neighbourhood of Villa Rica; and copper in Minas Novas. The diamond occurs in greatest abundance in a district of the Serra do Frio, sixteen leagues from north to south, and eight from east to west, known by the designation of the diamond district. The little that is known of the territory of Matto Grosso, and the sources of the Tocantins, induces a strong belief that this gem is likewise to be found there. It is found in a stratum, of variable thickness, of rounded quartz-ore pebbles, cemented by an earthy matter. They are found along the banks of rivers, and in cavities and water-courses on the loftiest mountains. They occur in immense beds. Häy disregards the distinctions supposed to exist, in the hardness and form of the crystal, between the diamonds of Brazil and those of the East Indies. Lapidaries and jewellers continue to believe that the oriental diamonds have a finer water. Topazes occur in nearly the same localities as the diamond. They are found among a conglomerate of friable earthy talc, quartz, and crystals of specular iron ore; and they are of many colours, yellow, white, blue, aqua-marine, &c. The chryso-

Physical
Geography.

beryl, ruby, amethyst, and green tourmaline, have been found in the Serra dos Esmeraldos. Martius states that coal appears in the mountain district, but does not specify any locality. He explicitly asserts that none occurs in the valley of the Amazons. Vast quantities of culinary salt effloresce from the soil during the dry season in the upper districts of the Paraguay. Saltpetre is likewise said to be a product of the province, but upon questionable authority. In the upper district of the Rio San Francisco immense deposits of marl occur, strongly impregnated with this latter salt; so strongly, indeed, that the wells and rivulets contain a perceptible solution of it. In the neighbourhood of Arrayal are some caves which yield annually about 2250 cwts. of saltpetre. In Piahy quantities of alum have been found efflorescing from the sandstone. The only fossil remains of animated beings occurring in Brazil of which we have any authentic account are found in these caves. Martius and Döllinger maintained that they correspond in every respect with the Megalonyx of Cuvier. They are scattered about in a fine greasy earth, which covers the limestone to the depth of eight inches. Bones, supposed to have formed part of a mammoth, have been found in Minas Geraes; and similar remains have been discovered in Bahia, near the Rio Solitre, and in Pernambuco. Bones resembling those of the megatherium, found in Paraguay, and now in the cabinet of natural history at Madrid, are said to have been seen near the Rio de Contas. We are not aware that any volcanic appearances have been observed in Brazil, unless the vague stories of hills where subterranean noises are at times heard may be supposed to indicate something of the kind.

Meteorology.

A country so extensive as Brazil, and so diversified in its surface, necessarily exhibits a considerable variety of atmospheric phenomena. The greater portion lies within the tropics, and has consequently the periodical interchange of wet and dry seasons. The narrow valleys, exposed to great heats, and surrounded by lofty mountains, have the vapours forced down upon them, and have a moist atmosphere. The high plains of the interior, and the extensive level region of the northern coast, and the summits of the mountains, are comparatively dry. The wide valley of the Amazons, with its "boundless contiguity of shade," and "lakes, and ocean streams," is most subject to moisture. At Rio Janeiro, nearly on the level of the sea, and in lat. 22. 50. S. the thermometer of Reaumur indicates, on an average, during the months of September, October, and November, a mean temperature of 20° 49'. The highest observed by Spix and Martius was 23° 49', the lowest 15° 49'. The rainy season lasts from October to March, and is heaviest in February. In September the hygrometer stands on an average at 49°, in October at 76°, in November at 85°. Owing to the proximity of the mountains, and the cooler atmosphere at their summits, the mists generally settle around their brows with considerable density towards evening. At Cachoeira, in the neighbourhood of Bahia, about the thirteenth degree of south latitude, and only six Parisian feet above the level of the sea, the thermometer of Reaumur gave, in February 1819, between six and seven in the morning, 17° to 19°, mid-day 25°, sunset 21° 23'. In Bahia itself the temperature at sunset is said to vary in the rainy season (September to March) from 17° to 18° Reaumur; in the dry months from 16° to 17°. The cloudless mid-day sun causes an extraordinary heat in the town; the sea breezes render the mornings and evenings cool; but the nights are warmer. At Oeyras, the capital of Piahy, in about seven degrees of south latitude, and 779 feet above the level of the sea, the thermometer of Reaumur varies in the warm months at mid-day from 29° to 30°. Martius

found it vary during the day as follows:—morning 23° 35', mid-day 24° to 25°, evening 23° 30'. He does not mention in what month this was. The driest months are July, August, and September. The south wind prevails during these months. The climate is healthy. Throughout the course of the Amazons the mean temperature is 22° of Reaumur; the lowest being 13°, and the highest 38°. Thunder storms are frequent and violent in the highest degree. We have no observations with the hygrometer. S. Paulo, situated in lat. 23. 33. S., is 1200 feet above the level of the ocean; and having a westerly declination of the surface of the ground, is consequently shielded from the sea breezes. The average temperature is 22° to 23° of the centigrade thermometer. The rainy season commences in November, and lasts till April. The greatest quantity of rain falls in January. Hoar frost is sometimes seen in the cold months. The prevalent winds are affected by the place of the sun: when he is in the northern signs, south-south-west and south-east winds prevail; when he is in the southern they are more variable. Villa Rica is situated in lat. 20. 27. S. about 3760 English feet above the level of the sea. It is overshadowed by the huge mountain Itacolumi, the summit of which is 5710 feet above the sea, and surrounded by mountains on all sides. Here the average indications of the thermometer are, morning 12° Reaumur, mid-day 23°, evening 16°, mid-night 14°. When the thermometer stood at 16° Reaumur on the summit of Itacolumi, it was found to be at 22° in Villa Rica. The temperature is agreeable enough to the sense, but the thunder-storms are frequent and violent. The wind among the mountain ranges is very variable, but cooling, from whatever direction it happens to blow. The cold weather in the months of June and July has frequently been known to affect the fruits. Respecting the temperature and other skyey influences of the high inland plateau of Matto Grosso we are entirely in the dark; but the Russian expedition under Langsdorff in 1826–29 must have made many important observations, although they have not yet been given to the public. Meteors are extremely frequent in the middle regions of the atmosphere in Brazil. Martius and Spix describe an immense mass of meteoric iron which they examined on their route from Bahia to Oeyras. Its estimated weight is about 17,300 Parisian pounds, it measures from 31 to 32 cubic feet, is extremely hard, and occasionally crystallized, and breaks in some places with a shelly impression.

Except on the loftiest mountains, and on the wide *sertões*, the vegetation of Brazil is luxuriant beyond description. In the mountain passes in the neighbourhood of the sea shore, the conjoint effects of heat and moisture produce a superfluity of vegetable life, which man's utmost efforts cannot restrain. Trees split for piling in the neighbourhood of Rio Janeiro send forth shoots and branches immediately, and this whether the position of the fragments be that in which they originally grew, or inverted. On the banks of the Amazons the loftiest trees destroy each other by their proximity, and are bound together by rich and multiform lianas. In the province of Maranhão, the roots, grasses, and other plants, extending from the shores of pools, weave themselves in time into a kind of vegetable bridge, along which the passenger treads, unaware that he has left the firm earth, until the jaws of a cayman protrude through the herbage before him. The vegetable productions of Brazil have a strong analogy with those of Guiana. The most common are the *compositae*, *legumina*, *euphorbia*, *rubiaceae*, *aroides*, and ferns of the most varied forms. The vegetation of the valleys differs from that of the *campos*, as it again does from that which occurs in the *sertões*. Along the coast, the *mangles* are the most numerous and prominent spe-

cies. The most marked peculiarity of this class of plants is, that the seeds begin to shoot before they drop from the parent plant, and that the drooping branches strike roots into the soil. They are never found inland except where the surface is scarcely elevated above the level of the sea. They flourish from Rio Grande do Sul to Maranhão, converting the land into a morass wherever they are allowed to flourish unmolested. Immediately behind them numerous families of palms raise their graceful heads. The underwood in the neighbourhood of Rio Janeiro consists principally of crotons. Every large river of Brazil has its own appropriate form of vegetable life, giving a peculiar character to its banks. The vegetation of the Amazons may be divided into three classes: 1. that which we find on the islands; 2. the vegetation upon the banks overflowed at regular intervals by the stream; 3. that which stands high and dry. The difference between them consists in the character of the bark and the species of the plants. Brushwood and herbage are nowhere to be seen: every thing tends to the gigantic in size. The most various forms group awkwardly together, crossed and intertwined with leaves. The preponderance of trees with feathery foliage, and with glossy, fleshy leaves, lends alternately a tender and a luxuriant character to the scene, which is in every other respect painful from its monotony. Representatives of the most estranged natural families grow side by side. It is only on the islands, where the willow and some other plants are found in numbers, that we are reminded of the monotony of our northern vegetation. Cocoa trees and the vanilla, *capsicum frutescens* and different kinds of pepper, the cinnamon tree and Brazilian cassia, abound. The flora of all the tributaries of the Amazons is similar to what we have described, until the traveller ascends above the falls, and finds himself in another region. The sources of the Madeira alone offer a partial exception, retaining a vegetation indicative of extensive plains, lakes, and morasses. The vegetation of the southern *campos* (corresponding to the North American *prairies*) is widely different. On the plains of the southern provinces we find scattered about strong tufts of greyish-green and hairy grasses, springing from the red clay. Mingled with these are numerous herbaceous flowers, of the most varied colours and elegant forms. At intervals small groves of trees, seldom exceeding twenty feet in height, so distant that the individual form of each is easily recognised, with spreading fantastic branches and pale green leaves, break the monotony of the scene. Solitary myrtles, numerous varieties of pleasing fruits, and now and then a cactus, add to the variety. A similar vegetation, but with a richer variety of plants, occurs in the diamond district. On the western declivity of the Serra do Mar, and along the upper banks of the Rio San Francisco, extends a wooded country, but of a character entirely different from that which is found in the valleys below. The name Cattingas is applied to the forests in both of the above-mentioned districts, although their characters are entirely dissimilar. The term merely expresses that they cast their leaves during the dry season, and push them forth when the rains return. *Malva*, *euphorbiaceae*, *mimosae*, and such like, are the prevailing types on the Rio Francisco; cactuses, palms, and ferns, abound on the Serra do Mar. In this latter district the Ipecacuan flourishes best. It is, however, in the glowing steppes of Pernambuco that we find the cactus predominant. In the valley of the Paraguary the most striking feature is presented by the water plants, which in one river are sufficiently strong to impede the navigation of a stream both deep and broad.

The jaguar, the tapir, the pecari, the agouti, and many other animals, are common to Brazil with the rest of the South American continent. The *simia* are numerous,

and the *simia apella* and the *simia cedipus* (the smallest known species of ape) are indigenous to the country. The *simia jacchus* has never been seen elsewhere. There are several varieties of bats, of which the *vespertilia sorcinus* and the vampire bat are the most dangerous. Two species of sloth, the *Bradypus tridactylus* and *didactylus*, are not uncommon. The Brazilian birds are celebrated for the beauty of their plumage. "Red, blue, and green parrots," says Malte-Brun, "frequent the tops of trees. The galinaceous *jacus*, the *hocos*, and different kinds of pigeons, haunt the woods. The orioles resort to the orange groves; and their sentinels, stationed at a distance, announce with a screaming noise the approach of man. Chattering manakins mislead the hunter; and the metallic tones of the uraponga resound through the forest like the strokes of a hammer on an anvil. The toucan (*Anser Americanus*) is prized for its feathers, which are of a lemon and bright red colour, with transversal stripes reaching to the extremities of the wings. The different species of humming birds are more numerous in Brazil than in any other country of America. One sort is called by the people the *Gnanthe engera* or winged flower." The gayest butterflies flutter through the air, the blue shining Menelaus, the Adonis, the Nestor, and the Laertes. More than ten species of wild bees have been observed in the woods; and the greater number produce honey. The *cactus coccinellifer*, and the insect peculiar to it, are found in the province of S. Paulo. Ants are numerous and destructive, particularly in the southern provinces. Snakes, of which the *sucuru* is the most venomous, are frequent in moist places. Lizards and caymans abound. The quantity of turtle in the Amazons and its principal tributaries is almost incredible. The waters swarm with fish, of which the only one entitled to notice in a sketch like this is the paranha, the tyrant of the fresh waters, which divides with the cayman the terror and hatred of the inhabitants.

III. *Statistics*.—In the first division of this sketch we have pointed out how Brazil was gradually discovered and peopled. In the second we have attempted to describe the character of the land, and its natural products. It only remains to show the present number, condition, and character of its inhabitants, and how far they have availed themselves of the natural wealth which has been placed at their disposal. In the prosecution of this object we shall endeavour to exhibit a view, 1. Of the amount and distribution of the population of Brazil, according to the latest authorities; 2. Of its social constitution, political, judicial, ecclesiastical, and military; 3. Of the character of its citizens in regard to their capacities of taste and intellect, and to their moral power; 4. Of the state of national industry and wealth in agriculture, manufactures, and trade foreign and domestic.

1. The latest authentic accounts of the population of any province of Brazil which have been received only reach to the year 1823; and the notices of the population at different periods are too scanty, and too indifferently authenticated, to admit of our deducing from them a ratio of increase by means of which we might estimate the present probable number of inhabitants. Besides, the circumstances of the different provinces vary too much to warrant an extension of the estimated ratio to those respecting which the data are defective or imperfect. For these reasons we are under the necessity of stating, with more particularity than we should otherwise have done, the data which we are really possessed of.

From the province of S. Paulo we possess authenticated lists of the population in the years 1808, 1813, 1814, and 1815. For the last of these years we have the numbers of white, black, and copper-coloured inhabitants; of males and females; of the births, deaths, and marriages

Statistics. within the year, specifically stated. The round numbers and in 1815, 215,021. In 1815 this sum total was made up Statistics are, in 1808, 200,478; in 1813, 209,219; in 1814, 211,928; of the following parts:—

WHITES.		NEGROES.				INDIANS.			
Male.	Female.	Free.		Slaves.		Free.		Slaves.	
		Male.	Female.	Male.	Female.	Male.	Female.	Male.	Female.
54,993	60,110	2,210	2,656	22,917	16,808	20,480	23,805	5,296	5,746

This population of 215,021 souls was scattered over a territory nearly of a square form, extending from twenty to twenty-seven degrees of south latitude, and from forty-six to fifty-five of west longitude. This extent gives an average of less than one inhabitant to each square mile. But 59,139 souls, or nearly one third of the whole, inhabit one city and three market-towns; a fact which affects the average density of the population. The number of births in 1815 was 10,106, of marriages 3120, and of deaths 4636. The deaths were to the whole population in a ratio of one to 46.38; the births were in a ratio of one to 21.28; and the deaths were to the births in a ratio of one to 2.18. According to this proportion the population ought to double itself in little more than twenty-one years. But the real increase from 1808 to 1815 is, as nearly as may be, seven per cent.; and, according to this proportion, the population ought to double itself in less than sixteen years. Making allowance for the influx of emigrants from Europe, and the increase of manufactures, this latter ratio is probably nearer the truth. We have therefore for S. Paulo, at the close of 1831, a population of 430,042; but owing to the establishment of manufactures, and the influx of settlers, it is probably even more numerous.

Minas
Geraes.

The province of Minas Geraes is nearly 400 miles in length from north to south, and 280 in medium breadth. It lies due north of S. Paulo, more inland, equally elevated, and with a more uneven surface. Its population in 1808 was as follows:—

RACES.	FREEMEN.		SLAVES.		TOTAL.
	Males.	Females.	Males.	Females.	
Whites.....	54,157	52,527			106,684
Half Blacks...	64,406	65,250	7,857	7,880	145,393
Negroes.....	23,286	24,651	86,849	46,186	180,972
Total.....	141,849	142,428	94,706	54,066	433,049

An estimate of the population of the same province in 1820 makes it amount to 456,675 freemen and 165,210 slaves; in all, 621,885. This statement is not however sufficiently authenticated. It is worthy of remark, that in 1808 Minas contained, with only the double of the population of S. Paulo, three and a half times as many black slaves, and nine times as many free negroes. The disproportion betwixt the numbers of male and female slaves is yet more glaring than in the last-mentioned province. The population of Minas is also less stationary. The Comarca of Villa Rica, which was held to contain only 72,209 inhabitants in 1813, is said to have had 78,618 as early as 1776. It may be remarked, however, that of late years agricultural and manufacturing industry have borne more healthy proportions to gold finding. Could we trust in the accuracy of the return of 1820, the population of Minas must have doubled since 1808, and must now amount to about 860,000 souls.

Bahia.

The population of Bahia amounted in 1823 to 592,908

souls, who were thus distributed over a surface of 84,000 square miles:—

Comarca da Bahia.....	362,503
Comarca da Jacobina.....	56,000
Comarca dos Ilheos.....	75,569
Capitania de Sergippe d'el Rey.....	98,836
	592,908

The great superiority of numbers in the Comarca da Bahia is mainly owing to the number of negroes employed in the four hundred *engenhos* (sugar factories) within the *reconcavo*, or valley surrounding the great inland sea, upon which the city stands. By referring to the table given above of the population of S. Paulo, the reader will see that there is a marked excess of male above female negro slaves; a proportion which also obtains in other provinces of Brazil. This fact, and the hard labour to which the class in question is condemned, forbid us to assume an equally speedy increase of their numbers with that of the other inhabitants. It is only in Sergippe d'el Rey that we have any data for guessing at the real increase.

In 1808 it contained 72,236
In 1823 98,836

An increase in fifteen years of 26,600; or a little more than one third of the original population. Assuming the same ratio of increase to have held throughout the province since 1823, it would give us, for 1831, 790,544 souls.

We possess a return for Pernambuco in the year 1823, Pernambuco of 234,000 inhabitants. Subjoined to this return are lists of buccos the population of the northern sea-board provinces, Alagoas, Paraiba, Rio Grando do Norte, and Seara. These districts are extremely similar in their physical characteristics. The total of their inhabitants in 1823 was 654,800; while the number resident in Seara was 140,000. According to the parish registers, the same province, in 1813, contained 131,140; giving an increase of 8860, or something more than one fifteenth, during ten years. Other but less trust-worthy accounts make the population double in twenty-five years.

The two provinces of Para and Rio Negro include the Para whole basin of the Amazons. In 1820, a priest, resident at Rio Negro Para, who had bestowed great pains on the subject, stated the result of his investigations to Drs Spix and Martius as 83,510 for both captaincies. Of these he attributed 68,190 to Para, and 15,320 to Rio Negro. A return, in like manner including both provinces, was presented to the same gentlemen in 1823, representing their united population as 173,125. It appears that the wild Indians are reckoned here, and that they had been omitted in the return of 1820. In 1814 the population of Rio Negro was stated, in a very distinct and articulate report, to amount to 15,235 souls, being only 85 short of the sum attributed to it in 1820. This is in some degree accounted for by the fact that Martius, in the latter year, found the population in more than one district much decreased below what it had been six years before. Of the total population of Rio Negro 11,435 were Indians. Upon such data no calculations of

Statistics. the probable increase are admissible. The following table enumerates the latest returns of every province from which any have been made, stating at the same time the authority upon which they are here given.

Province.	Date of Return.	Authority.	Population.
Rio Grande do Sul, (Environs of Rio Grande).....	1806	Mawe.....	100,000
Uruguay.....	1801	Henderson.....	14,010
S. Paulo.....	1815	Martius.....	215,021
S. Catharina.....	1813		33,049
Rio Janeiro (town alone).....	1817		110,000
Espirito Santo.....			
Porto Seguro.....			
Bahia } Sergippe d'el Rey }	1823	Official returns	592,908
Minas.....	1820	De Barbacena..	621,885
Goyaz.....	1821	Official returns	37,250
Matto Grosso.....			
Pernambuco.....	1822	De Barbacena..	234,000
Alagoas.....			91,800
Paraiba.....			120,000
Rio Grande do Norte.....			64,000
Seara.....			140,000
Piahy.....	1819	Official returns	71,370
Maranhão.....	1821	Adr. Balbi.....	182,000
Gram Para.....	1820	Martius.....	68,190
Rio Negro.....			15,320

The total of these sums amounts to 2,809,803. It must, however, be taken into account that some of the returns are of an old date; that for three provinces there are none at all; and that in the cases of Rio Janeiro and Rio Grande do Sul only the inhabitants of the capital and suburbs are enumerated. We are therefore entitled to assume that in 1820, the medium year, the population of Brazil would probably have been underrated if estimated at 3,000,000. The time in which the population of Brazil doubles itself appears to vary in different provinces from fifteen to thirty years. The circumstances of the last ten years are such as to entitle us to believe that the inhabitants of that empire are now little short of 5,000,000.

This population is composed of the descendants of the aborigines, of negroes, and of persons of European descent. Here, as everywhere else, the copper-coloured race gives way before the other two. It is calculated that, on an average, 50,000 negroes are annually imported into Brazil. The great disproportion, however, between the numbers of males and females, noticed above, and the natural tendency of human beings to multiply slowly in a state of slavery, seem to prevent any thing like a corresponding increase of numbers. By means of the numerous immigrations from Europe, the white race has hitherto been able to keep its ground. Of all the crosses between the different races, the mulatto seems to take most kindly with the soil and climate of Brazil. In S. Paulo in 1815 the total of white persons was 115,103; of negroes, 44,591; of Indians, 55,327. In the city of Rio Janeiro in 1817 a native Indian was a rarity; of 110,000 inhabitants it was estimated that two thirds were negroes. In Minas in 1808 the number of Europeans was 106,684; of persons of mixed blood, 145,393; of negroes, 180,972. The united population of Gram Para and Rio Negro amounted in 1820 to 83,510 souls. Of these, 50,000 were, according to a rude estimate, Indians. In 1814 Rio Negro alone con-

tained 15,235 inhabitants, of whom 11,435 were Indians, 3,071 free whites and negroes, and 729 slaves without distinction of colour. The law of Brazil admits the distinction between freeman and slave; but once free, every individual without regard to colour, is equal in the eye of the law.

2. As nothing has a greater share in impressing upon a Political nation its peculiar character than the form of its government, it will be necessary to make ourselves masters of the social institutions of Brazil, before we can attempt to judge of its citizens either in their moral or economical relations. Brazil is a constitutional monarchy, without a privileged aristocracy. In such a state the monarch can only act in consonance with the laws. It will therefore be advisable, in the first place, to give some idea of the representative legislature, which is thus endowed with the power of regulating his actions.

The legislative power is vested in the general assembly, consisting of two chambers, that of deputies and that of senators. The deputies and senators are nominated by indirect election; the body of qualified citizens choosing the electors in parochial assemblies, and the latter nominating the provincial representatives. The existing provinces, enumerated above under the head of population, may be subdivided, and each portion erected into a province whenever the increased number of inhabitants justifies such a step. The qualification for an elector is an annual income of 200 milrees; that of a deputy an income of 400. Minors, military officers, priests, monks, servants, and paupers, are incapable of voting; naturalized foreigners, and persons not professing the religion of the state, are incapable of being elected. The deputies are elected for four years, in each of which there must be a session of four months, opening on the 3d of May. The senators are elected for life. Every province has a number of senators, equal to half its number of deputies; but they are nominated in triple lists, from which the emperor selects one third at his pleasure. A senator must be forty years of age, and possess a clear annual income of 800 milrees. The salary of a senator is one half more than that of a deputy. Each house nominates its own officers. When the two houses sit in general assembly, the president of the senate presides, and the senators and deputies sit promiscuously. They assemble in this way to take the oath of the emperor; to elect a regent; to nominate a tutor to the emperor when minor; on the death of an emperor, to institute an inquiry into the administration which has just concluded, and to reform abuses; and to select a new dynasty, in case the old has become extinct. They sit apart, and proceed by way of bill, when they make laws, interpret, or suspend them; they determine the public charges, and assess the direct contributions; fix the ordinary and extraordinary forces by sea and land, on the report of the government; authorize the contraction of loans by government; regulate the administration of national domains, and decree their alienation; create and suppress public employments; control weights and measures, and the standard of exchange. The chamber of deputies has the initiative in taxes, in recruiting, and in the choice of a new dynasty. The senate has the exclusive privilege of taking cognizance of offences committed by members of the royal family, counsellors of state, senators, and deputies, during the time of session; of enforcing the responsibility of secretaries and counsellors of state; of convoking the assembly, in case the emperor fail to do so within two months after the period fixed by law; and also of calling it together on the death of the emperor. The assembly, in addition to its legislative powers, is likewise entitled to act as the emperor's great council of state.

In accordance with the counsels given and the laws

Statistics. enacted by this body, the emperor exercises the supreme executive functions of the state. This he does through the instrumentality of his ministers, who are responsible for treason, corruption, abuse of power, acts contrary to the liberty, security, or property of subjects, and waste of public property. From this responsibility they cannot escape upon the plea of orders from the emperor. The executive functions are, the convocation of the general assembly; the nomination of bishops, governors of towns and provinces, commanders by sea and land, and ambassadors; the formation of alliances and the initiative of foreign negotiations; the declaration of peace and war; the granting letters of naturalization, &c. The ministers are, secretaries of state, of transmarine affairs and marine, and of foreign affairs; a head of the treasury, with a grand and second treasurer, a director of the bank, and a fiscal; a head of the board of trade; a president of the consistorial board; a commander in chief, and a head of police, with his lieutenant. To these is adjoined a council of state, composed of ten members nominated by the emperor, and having the imperial prince, if of age, for president. With these counsellors and assistants the sovereign manages the national affairs. Matters of local economy and municipal police are regulated in the provinces by presidents nominated by the sovereign, and removable at pleasure, checked by elective chambers of districts; in the cities and towns, by councils of management elected by the inhabitants.

Financial system.

The financial arrangements of Brazil fall under two heads, the general and national, administered by the head of the treasury and his subordinates, under the control of the chambers; and the local, exercised by the provincial authorities, under the corresponding check of "the councils general of the provinces" and the municipal councils. The general assembly controls the management of those revenues which, formerly appertaining to the crown, are now termed national; it determines the annual expenditure, and assesses those taxes which are necessary in addition to the income from the domains and regalia. The customs payable on goods passing from one province to another have been remitted. All exports of Brazilian produce pay a duty of two per cent. Imports from Portugal and England pay a duty of fifteen per cent. Foreign wines pay thrice the duty laid upon those of home growth; and foreign brandies twice and a half. All other merchandises pay a duty of twenty-four per cent. Slaves pay an additional duty, the half of which is deposited in the bank to form a fund to aid in settling colonies of Europeans. The direct taxes are, *dizimo*, a tenth levied upon all products of agriculture, pasturage, and the fisheries; *subsídio nacional*, an import upon fresh meat, hides, brandies, and cotton cloth prepared within the land; a capitation tax for the bank of Brazil from every merchant and tradesman; a tax upon official incomes, &c. These are collected into the treasury, partly by the agency of salaried officials, but more frequently by means of the Bank. This institution farms most of the regalia; and, in the matter of customs and imposts, it is in the habit of making advances upon the pledge of the yet unliquidated duties. The financial arrangements of the provinces are those of the state in miniature. The repeal of all duties paid upon the transit of merchandise from one province to another; the immense sums surreptitiously carried off by the greedy court of Joam VI. when he fled from Rio; and, above all, the commotions of the last ten years, co-operating with the inefficiency of the late head of the government, threw the finances of Brazil into a state of derangement from which they have not yet recovered. In September 1823 the state debt amounted to 30,500,000 cruzadoes. The estimated ordinary revenue for the half year, 1,767,000 milrees, was less than the

expenditure by the sum of 900,000. The local revenues were also equally deficient. The annual deficit of Minas Geraes amounted to 60,000 milrees; that of Goyaz to nearly 20,000; that of Matto Grosso to 10,544; that of S. Catharina to 34,870; and so of the rest. The charges thrown upon the treasury by these deficiencies amounted to 280,000 milrees yearly. Recourse has been had to forced loans and contributions, to donations, sequestrations, and, finally, to a foreign loan; but the difficulties still remain unsubdued.

There are in Brazil justices of the peace, elected at the same time and in the same manner as the deputies. Without previously attempting a reconciliation with his adversary before one of these, no person is entitled to bring a cause into court. Trial by jury is the constitutional form in all courts of the first instance, both in civil and in criminal cases. There are courts of appeal in the principal cities. In Rio there is in addition a supreme tribunal of justice, in which judges, selected from the other courts, preside according to their seniority. The duties of this tribunal are to permit or refuse the revision of causes proposed to be submitted to the courts of appeal; to inquire into abuses committed by its own officers or those of other courts, of persons connected with the diplomatic body, and of the presidents of the provinces; and to investigate and decide on disputes respecting the jurisdiction of the provincial courts. In the courts of the first instance, which are twenty-four in number, one in each comarca of the empire, a judge entitled *Ouvidor* presides. Appeals lie from these to the courts of the second instance, at Para, Maranhão, Pernambuco, Goyaz, and Bahia, whose decisions are reviewable by the *Relação* of Bahia; Rio Janeiro, Minas Geraes, Matto Grosso, and S. Paulo, are reviewable by that of Rio. All judges are responsible for abuses of power, and for corruption, but can only be displaced in consequence of a sentence. In an imperfectly settled country, and where some traces of the feudal character of its first organization may yet be found in the language of the laws and the intermingling boundaries of districts, disputes regarding jurisdiction are of too frequent occurrence. The body of the law has been transplanted from Portugal, occasionally modified by new relations or later enactments, but, in the main, a scarcely coalescing mixture of the Roman and canon law, with enactments the native growth of the mother country.

The Catholic Apostolic Roman religion is the religion of the empire. All other religions are tolerated, and allowed a domestic celebration of their rites, but without any external form of temple. The church of Rome being in its leading characteristics the same throughout the world, a particular description may be here dispensed with. There is one archbishopric in Brazil, that of Bahia. Its suffragans are the bishoprics of Rio Janeiro and Pernambuco. Maranhão, on account of the difficult navigation between that town and Bahia, had its bishopric subjected to the archiepiscopal jurisdiction of Lisbon. It is now independent. The diocese of Para was so from the first. The district originally subjected to the bishop of Rio Janeiro has subsequently been subdivided, in order to erect the additional dioceses of S. Paulo and Mariana, and the prelacies of Goyaz and Matto Grosso. The whole of Brazil is subdivided into parishes, to each of which one or more officiating priests are attached. Government has expended little money on the clergy, but this omission has been abundantly supplied by legacies and donations from individuals. There are several cloisters of Franciscans and Dominicans, and an immense number of Hermits.

Among the ministers of the empire, we have mentioned a head of the literary department. One of the most important taxes imposed by government is the *subsídio* ment

Statistics. *literario*, an impost for the maintenance of teachers, upon every ox killed in the shambles; upon rum, and in some provinces upon the salted provisions brought from the interior. In every *villa* (market-town) there is a "Latin school," an institution for teaching the elements of language and an acquaintance with the classics. In S. Paulo, Bahia, and Maranhão, we find gymnasia, with somewhat higher pretensions. In every episcopal seat there is a theological seminary, in which candidates for orders are obliged to pass a certain number of years in the study of philosophy and divinity. In 1827 two schools of law were instituted, one at S. Paulo and one at Pernambuco. The course lasts five years. The first two are devoted to prelections on the law of nature and of nations, and an analysis of the constitution; during the third and fourth, the laws of Brazil, maritime and mercantile law, are the subject of study; during the fifth, political economy and finance. For such as wish it, there is a course of canon law during the second year. Rio de Janeiro possesses a lyceum and an *aula de cirurgia*. In the former of these are taught Latin, Greek, French and English, rhetoric, geography, mathematics, philosophy, and theology. In the latter, the students are bound to attend, during the first year, anatomy, chemistry, and pharmacy; during the second, the same, with the addition of physiology; during the third, pathology, therapeutics, and the practice of medicine; during the fourth, surgery and midwifery; during the fifth, clinical surgery. The students have admission to the military hospital, and such as choose may attend the lectures on botany and natural history, the botanical garden, and the museum. There is also in the capital a military and a commercial academy. In addition to the public institutions for the promotion of education here enumerated, schools of mutual instruction have of late years been founded in most towns and cities by private individuals.

Army and Navy. 6. The constitution of Brazil recognises the necessity of a permanent naval and military force, but without determining its amount. It can only be assembled by legitimate command, and is under the executive power. Officers of the army and navy cannot be deprived of their commissions but by the sentence of a competent tribunal. In 1826 the regular army was estimated by General Miller at from 15,000 and 16,000 men. Of these, 3500, consisting partly of foreigners, were stationed in the capital; and the rest were dispersed throughout the provinces. Thus, in S. Paulo there might be a regiment of dragoons and one of infantry, in detachments on the coast, at the capital of the province, and at the custom-houses on the frontier. In Bahia the troops of the line generally amounted to upwards of 3000 men, infantry, artillery, and cavalry. In 1823 the Brazilian navy consisted of one line of battle ship carrying seventy-eight guns; three frigates carrying forty-four, thirty-eight, and thirty-two; two corvettes carrying thirty-two and twenty-two; two schooners carrying twenty and sixteen; a fire-ship and a gun-boat. Besides the regular troops, every Brazilian capable of bearing arms is enrolled either in the *milicias* or the *ordenanzas*. The former are commanded by chiefs of their own appointment (*coroneis*), having under them a major from the regular army, appointed by government; they are subject to military law, and liable to serve, in case of need, beyond the limits of the province; they receive no pay. The *ordenanzas* are commanded by *capitães mórés*; they are only liable to serve in case of invasion; and they discharge in a great measure the duties of a local police. General Miller speaks slightly of the regular troops of Brazil; and here we believe him to be in the right. Its *milicias* and *ordenanzas* he regards with the supercilious contempt natural to a military man; and here we believe him to be in the wrong.

Statistics. 3. It is obvious, from the insufficient establishments for general education, that the intellectual development of individuals must be achieved in a great measure by unaided exertion. In the more thinly inhabited districts devotion to such pursuits must not be expected in men exclusively occupied in procuring subsistence and securing self-defence. Even where the population is more dense, a lazy feeling of animal comfort represses the exertions of the majority. It is among the more aspiring class, who aim at the learned professions or state employment, and who are consequently obliged to cultivate their minds, that we must look for that attachment to intellectual pursuits which is rarely acquired except from habit. In the theological seminaries established at the seat of each bishop, little more is inculcated than a knowledge of the classics, an outworn scholastic system of logic, and a knowledge of the routine duties of a priest. This is a system of tuition only calculated to deaden the mental faculties. The school of medicine in Rio Janeiro, from the attention bestowed upon practical surgery and anatomy, has done more to awaken the mind; but this is only one bright spot in a realm of darkness. The number of situations under government requiring a certain knowledge of practical mathematics and natural history, rendered necessary by the system of working the mines so long pursued, has been more efficient in diffusing throughout the empire a knowledge of and a taste for these kindred pursuits. The number of foreign engineers and naturalists encouraged to settle in Brazil has rendered the natives in some measure acquainted with all that has been of late achieved in Europe in the mathematical and experimental sciences. Late events have forced upon the inhabitants a number of political questions, which, coming home to every man's business and bosom, have excited the whole community. As yet, however, the intellect of Brazil seems to be rather in the process of awakening to a consciousness of its existence, than capable of effecting any thing. Printing presses are everywhere sought after. In 1823, Rio alone had thirteen political journals, the other towns and provinces in proportion. Several attempts had been made to establish periodical publications devoted to geographical and natural science. New libraries were founded, and the old ones extended and better arranged. But nothing new has yet been produced in Brazil beyond the contribution of additional facts in mineralogy, botany, and astronomy. The power of systematic and independent thinking has not yet shown itself.

In the matter of taste, the Brazilians have only added one poet to the literature of the Portuguese language. Gonzaga was at one time ouvidor in the Comarca of S. João d'el Rey in Minas Geraes; but having taken part in an attempt to revolutionize the province about the commencement of the French Revolution, he was banished to Angola, where he afterwards died. His poems are all lyrical. A collection of them has been published under the title "*Marília de Dircea*;" and many more are preserved by popular tradition. They are characterized by delicacy of fancy and diction, and tenderness of feeling. Everywhere in Brazil a strong native taste for music evinces itself. The native tribes, in contradistinction to the negroes, who evince feeling only for melody, are deeply sensible of the charms of harmony. Among all classes, however, the guitar and song form the principal evening's amusement. Spix and Martius found this to hold good among the courtiers of Rio de Janeiro, among the sturdy Paulistas, on the Sertões of Minas, and in the mercantile Bahia. The simplicity of the national instrument is unfavourable to the culture of a high order of music. In Rio, however, much was done under the patronage of Dom Pedro for the cultivation of the science, and not without effect.

Statistics. An academy of the fine arts has likewise been established in that capital for many years; but its ill success seems to betray a want of feeling for the beauties of painting and sculpture. The drama, which calls into requisition all these arts, is at a very low ebb. The actors are chiefly vagabond mestizos; and the decorations of the stage are on a par with the performers. In art and literature, as in science, those Brazilians who are enlightened enough to find pleasure in such pursuits, rely entirely upon the productions of other countries, principally those of France and England. The sensibility to imaginative pleasure exists, but the power of producing the objects which excite it is wanting.

We have prefixed these brief sketches of the progress of the Brazilians in knowledge and art to that of their moral condition, because the state of the latter is mainly dependent upon them. Only where wealth and a complicated state of society have developed the intellectual powers and refined the sentiments, can any thing approaching to elevated and consistent goodness be found. Within the limits of Brazil, and even without having recourse to her savage population, may be discovered specimens of every stage of moral development. In the populous cities on the coast, and in the seats of local government in the interior, there are men entitled to rank with the educated classes of any country in Europe. More enlightened minds, with greater power of self-denial and endurance, have been displayed nowhere than in the course of the Brazilian revolutions. The mass of the people, however, is entirely destitute of education, unrefined, and the creature of impulse. The continuance of the slave-trade tends yet more surely to harden their minds. The larger towns present the same spectacles of brutal excess in animal enjoyment among a certain class that we find in Europe. Murders are more frequent. The most elevated class of the population, in respect to the general diffusion of the sense of moral obligation, is to be found in S. Paulo and in Minas Geraes. The source of the superiority of the former has been adverted to in our historical sketch. In the latter, it may fairly be attributed to the prevalence of that sect which still persists in expecting the return of king Sebastian. Whenever a sect adopts as one of its first principles a high standard of self-control, we may be sure that the effect will be to ennoble the majority of its disciples. The scattered population towards the interior frontier presents not unfrequently specimens of the most daring defiance of every dictate of religion, reason, or human feeling.

The branch of national industry includes, agriculture, manufactures, and fisheries, or production; commerce, foreign and domestic, or distribution.

Agriculture.

4. In Rio Grande, the most southerly province of the empire, the soil is principally in pasture, and the chief occupation of the inhabitants the feeding of cattle. The animals are of a large size, and the herds are numerous. They are allowed to wander at large under the superintendence of a few half wild Creoles and Negroes. There are no dairy establishments. Butter and cheese are only made on particular occasions, and even milk for coffee is not always to be had. The quantity of wheat grown in the province is considerable, but farming is carried on in a slovenly manner. The grain is dirty, and apt to ferment. The island of S. Catharina, immediately to the north, has been cleared of its timber for the purpose of ship-building, and is almost entirely under cultivation. The agricultural produce of the island in 1812 is stated in an official paper to have been:—Mandioca meal, 388,361 alqueires; maize, 16,968 ditto; garlic, 16,506 ditto; onions, 10,472; wheat, 3365 ditto; rice, 18,723 quintals; coffee, 12,592 ditto; cotton, 2270 ditto; flax, 1798 ditto; mo-

lasses, 7118 pipas; sugar, 712 quintals; ox-hides, 35,900. Statistics. The wheat, it will be observed, bears but a very small proportion to those products which are most successfully cultivated within the tropics. What is commonly called in England colonial produce, begins here to be the staple, and continues so along the whole coast of Brazil, until we reach the equator. The province of S. Paulo is most densely inhabited, and consequently best cultivated along the coast. This is the reason why, with the finest and most extensive pastoral country in Brazil, the value of its cattle in 1814 did not amount to one fifth of the whole agricultural produce of the province. Coffee either does not succeed, or is not a favourite object of cultivation; for the quantity produced by this province is less than that which is grown in S. Catharina. Sugar has begun to improve, and continues to do so as we move northward. The produce of the sugar plantations of S. Paulo in 1814 was 122,993 arrobas of sugar, and 233 pipas of rum, independently of an immense quantity of sugar syrup prepared for home consumption. The quantity of mandioca raised in the same year was 111,460 alqueires; of maize, 723,989 ditto; of rice, 120,860; while of wheaten flour there was only 5050 arrobas. The colonial produce, in addition to sugar, was, cotton, 54,222 arrobas; tobacco, 9596 ditto; coffee, 4867 ditto; castor-oil, 179 canada. The most important agricultural products in the province of Rio Janeiro are sugar, coffee, and cotton. The first mentioned is cultivated most extensively between the mountains, and in the warm and moist district. In the neighbourhood of the capital itself we find the greatest quantity of sugar plantations. In 1817, 60,000 arrobas of sugar were exported from Rio, but whether it was all produced within the province, does not appear. The coffee of Rio Janeiro is esteemed the best in Brazil. This is owing to the instructions and example of Lesene, an intelligent gentleman of St Domingo, who, driven from home by the revolution in that island, commenced a plantation in the neighbourhood of Rio, and, through the superior demand occasioned by the excellence of his berries, stimulated his neighbours to follow his example. Rio produced 299,000 arrobas of sugar in 1817, and 470,846 in 1820; an immense increase in quantity, independently of the improvement in quality. We have no exact accounts of the quantity of cotton annually collected in this province. It is said to yield a less lasting cloth than the cotton raised in the more elevated and drier districts of the country. Some attempts made to introduce the tea plant in the neighbourhood of Rio have failed, apparently from want of perseverance. The trees look healthy and luxuriant; and a slight tinge of earthiness, which is perceptible in the flavour of the decoction of the leaf, is attributed by naturalists solely to the want of a sufficiently long acclimatization. A quantity of tobacco is raised in the islands of the bay of Rio; and, together with what is brought from Espirito Santo, it may amount, one year with another, to 30,000 quintals. Of the agriculture of the province just named, and its neighbour Porto Seguro, the preceding sentence contains all the information we have been able to collect. The chief agricultural product of Bahia is sugar, and the most luxuriant growth of its sugar canes is in the Reconcavo in the immediate neighbourhood of the city. The surface of the ground in its original state is covered with marshy hollows, which, when drained of their superfluous waters, are found filled with a light alluvial earth, most favourable to the growth of the sugar cane. This gift the skill of the Bahian planters has turned to the best advantage. Tobacco was wont to come next to sugar in the Reconcavo; at present it is most extensively cultivated in the neighbourhood of Cachoeira, though even there a falling off has been observed. There

Statistics. is proportionally little coffee raised in Bahia, and that little in the Comarca dos Ilheos, the rudest and most wretched district of the province. The fruit is much inferior to that of Rio, probably on account of the slovenly manner in which it is gathered and dried. Rice returns from two to three hundred times the seed. In the year 1817 the sugar raised in Bahia was estimated at 1,200,000 arrobas, the tobacco at 660,000, the coffee at 10,000, the rice at 18,000. Maize thrives here, but its cultivation is much neglected. An enterprising Swiss in 1817 set the example of forming artificial meadows in the neighbourhood of the city; and they are said by eye-witnesses to have equalled the best in England. The high price of fodder secured him an ample reward. The chief difficulty he encountered arose from the poisonous snakes which swarm in all marshy places. All kinds of European fruits and vegetables succeed in the Reconcavo, but are more exposed to the depredations of ants, snails, and birds, than native plants. The chief products of Pernambuco are vanilla, cocoa, rice, sugar, and cotton. The quality of the last-mentioned article grown in this province was at one time esteemed as the best in the world. Of late years it has much deteriorated, from neglect in the gathering and cleaning. Notwithstanding, the quantity exported in 1829 amounted to no less than 80,000 bags. In the interior of this province grazing is carried on to such an extent as has procured for it the title of the Switzerland of Brazil. The staple commodities of Seara are cotton and sugar. The other provinces along the coast, including Maranhão, exhibit nothing different in their agricultural products from those last described; on the shore the sugar-cane, farther inland cotton, and in the interior cattle. The produce of Gram Para presents nothing materially differing; that of Rio Negro, consisting chiefly of natural produce, scarcely comes under the head of agriculture. The provinces respecting the agriculture of which we have now to speak are the three great inland districts, Minas Geraes, Goyaz, and Matto Grosso. Of the last, too little is known to entitle us to say any thing. The agriculture of Goyaz is trifling, and almost identical in character with that of the interior of S. Paulo. The southern portion of Minas consists chiefly of pasture lands. Some attempts have been made to introduce oats, barley, and wheat; but these cerealia were found to run uniformly to straw, and their ears to ripen unequally. In the northern comarcas cotton has been cultivated with great success. In point of quality that of Minas Novas is esteemed second to none but that of Pernambuco. There seems, however, to be a great waste of surface in the mode of culture generally adopted. The land is first cleared for the plantation by burning, which is effected during the dry months. In January a number of holes are made in the earth about two or three feet apart, and five or six seeds are dropped into each and covered lightly with earth. The harvest occurs in the September of the second year. In the course of two years fresh ground is chosen and the same process repeated. The cotton-grower allows as long an interval as he can afford to elapse before he returns to a spot which has already been cultivated. This superficial view of the agriculture of Brazil argues a country of the most exuberant fertility, in which are not reared many products of the earth that might succeed; while the limited number produced, with the exception of coffee in Rio, and sugar in Bahia, are cultivated in a rude and slovenly manner. Cacao, ginger, various kinds of pepper, tobacco, and indigo, all of which experience has shown to be suited to the soil and climate, are neglected. Oxen, horses, and mules, are rather the gift of nature than the reward of assiduous attention.

Manufactures. Except a few rude manufactures for family use, this branch of national industry is in Brazil confined to mining

Statistics. operations, the smelting of metals, the polishing of precious stones, the manufacture of salt, ship-building, tanning and dressing hides, and the making of oil. In regard to the first mentioned, it may be observed that one most important mineral, coal, has hitherto only been discovered at two places in Brazil, Bahia and Rio Grande. At both, however, the smallness of the quantity and the situation of the veins has rendered working it with advantage impossible. On this account it has been necessary to employ charcoal in obtaining the metals from the ores; and hence everywhere in the neighbourhood of mines charring is a business which employs a good many hands. The wasteful manner in which the operation has hitherto been carried on is already beginning to be felt even in the immense forests of Brazil. Of late, however, scientific foresters have been encouraged by government to emigrate from Europe.

The diamond washings, with the exception of a few, Diamond of which but little is known, are confined to the diamond mines. district in Minas Geraes, and are still conducted on the ill-judged system of a government monopoly. The cascachao, mentioned above, is dug up and removed to a convenient place for washing. As much is raised during the rainy months as is expected to give employment to the slaves for the other six. It is deposited in heaps of from five to fifteen tons. A shed is erected in the form of a parallelogram twenty-five or thirty yards long and about fifteen wide, composed of upright posts supporting a thatched roof. A stream of water is conveyed down the middle of the area of this shed, covered with strong planks, on which the cascachao is laid two or three feet thick. On one side of the canal is a flooring of planks from four to five yards long, imbedded in clay, extending the whole length of the shed, and having a slope from the canal of three or four inches to a yard. This flooring is divided into twenty compartments or troughs, each of about three feet in width, by means of planks set on edge. The upper end of each trough communicates with the canal. Three overseers take their seats at equal distances on high chairs placed on the heaps of cascachao, on the side of the canal opposite to the troughs. As soon as they are seated a negro enters into each compartment, provided with a short handled rake, with which he draws to him fifty or eighty lbs. of cascachao. He then lets in water upon this, and keeps stirring it with his rake until the earthy particles are washed off; upon which, throwing out the largest stones, he carefully examines the rest for diamonds. As soon as he finds one he rises and holds it out between his finger and thumb; an overseer receives it from him, and deposits it in a bowl half full of water, suspended from the centre of the structure. At the close of the day's labour the diamonds obtained are taken from this deposit and delivered to the principal overseer, who weighs and registers them. On an average the mines yield 20,000 carats annually. The establishment is burdened with a load of debt incurred to foreigners for advances of money at the time that government first took it in hand. It is calculated that the diamonds cost government 33s. 9d. per carat. The washings give employment and support to a population of about 6000. The trade in gems which have not been deemed of sufficient importance to be claimed as regalia, centres in Minas Novas. The dealers in precious stones have their residence for the most part in Chapada. The greater part are sent in a state of nature to Bahia and Rio Janeiro; some, however, are polished, rudely enough, in the neighbourhood.

The gold country extends over Minas Geraes, Goyaz, Gold Matto Grosso, and part of S. Paulo. In all these districts the mines. winning of this metal is pursued in a manner exactly similar. It is found either in the beds of rivers, or in veins, at times

Statistics. twenty feet under the surface, at times close under the roots of the grass. Like diamonds, it is found intermingled with *cascalhao*. This mass, with the auriferous particles, is removed from its site to a convenient place for washing. Where water of a sufficiently high level can be obtained, the ground is cut into slips twenty or thirty feet wide, two or three broad, and one deep. Near the bottom is a trench two or three feet deep. On these steps the *cascalhao* is deposited, and on each stand six or eight negroes, keeping it in motion with shovels as the water flows gently upon it from above, until the whole is reduced to liquid mud and washed down. In the trench the particles of gold, from their weight, quickly precipitate. Other negroes are busy clearing away the stones and removing the surface mud. After five days' washing the precipitate is carried to some convenient stream. Here each negro is provided with a bowl of a funnel shape, about two feet wide at the mouth, and five or six inches deep. Standing in the stream, he takes about six lbs. of the sediment into his bowl, admits regulated portions of water, and keeps moving the sediment until the gold deposit itself at the sides and bottom of the vessel. He then rinses the bowl in a larger vessel of clean water, and begins again. This operation occupies about five minutes. When the particles of gold in the sediment are very minute, troughs similar to those employed in diamond-washing, but longer and narrower, are constructed. On their bottoms are stretched hides, tanned with the hair on, or pieces of rough baize. The water containing the sediment is conveyed down these, and the gold precipitating in the course is entangled in the rough surface. Every half hour the hides are carried to a neighbouring tank, stretched over it, dipped, and beaten repeatedly. The gold is found at the bottom of these reservoirs mingled with *esmeril*, from which it is separated by the aid of mercury. The whole business is carried on in a most cumbrous, inartificial, and wasteful manner. The gold thus procured is brought to the nearest mint, where the crown's fifths are deducted, and the rest refined and melted. The deliverer may either have his gold in the form of an ingot with the public stamp, or he may have a receipt for it, which entitles him to receive the amount from any mint in Brazil. This business gives employment to the great bulk of the population in Minas Geraes, in Matto Grosso, and in Goyaz. The amount of metal obtained we have no means of ascertaining with any degree of exactness. Minas alone, it has been calculated, yields, in the form of royal fifths, no less than 150 arrobas. The annual produce of Matto Grosso has been estimated at twenty arrobas. When the fifths were first imposed (in 1753) in Goyaz, they yielded annually a sum of £67,155; but since that period the quantity of gold obtained has been gradually diminishing.

Iron founderies.

The iron of Brazil has hitherto been almost entirely neglected, although no country is richer in this invaluable metal. In 1817-20 there were, as far as we have been able to learn, only the following iron-works in the empire: 1. That of Ypanema, in the province of S. Paulo. The immense deposit of magnetic iron ore in this neighbourhood was long worked in an unsatisfactory manner. In 1810 a company of Swedish miners and founders settled there, and erected two small refining furnaces. In 1807 they produced yearly 4000 arrobas of iron, which was manufactured on the spot into horses' shoes, nails, locks, and other articles. A larger establishment, with two smelting and several refining furnaces, and bellows moved by water, had been built at that time, but was waiting for workmen from Germany. Nothing more has been learned of its fate. 2. To the north-west of Antonio Pereira, near the centre of Minas, Eschwege erected a small iron foundery in 1816, and intrusted the

management of it to a German overseer. The daily produce was in 1818 two arrobas. It was worked up on the spot into hatchets, knives, bill-hooks, horse-shoes, and nails. 3. At Gaspar Soares, in the same province, a foundery on a large scale was erected in 1812 at the king's expense. It consisted of one smelting and two refining furnaces. The first mentioned had never been used, and the other two were lying idle when visited by Spix and Martius. The ore is excellent, and a canal might be dug at comparatively little expense, to the navigable portion of the Rio Doce. There were several furnaces in the province belonging to private individuals, and a considerable quantity of iron was brought from Rio, but still the supply was deficient.

The most important salt country in Brazil commences at the Rio de Salitre, a tributary of the Rio de S. Francisco, about six leagues from Joazeiro. At this place an artificial hollow extends along the river for the space of 60,000 square feet, and a fine, soft, ochre-coloured earth forms the bottom of the trough. The annual floods melt the saline particles contained in this mould; and when the river falls, a salt pool is left. The heat of the sun then evaporates the water, and the surface is left covered with hollow quadrangular pyramids of the salt. The soil is of a similar conformation along the bed of the S. Francisco for an extent of nearly two degrees of longitude, and everywhere nearly thirty leagues in breadth. Hollows, such as we have described, natural or artificial, are scattered over the whole extent. These are the salt-mines of the country. The greater number belong to the wealthy landholders on the Rio de S. Francisco; but many, especially on the western side, are yet unappropriated, and may be worked by any one. At certain seasons this district is visited by immense multitudes, some coming from very great distances. The earth is dug up to the depth of an inch, and deposited in wooden troughs; then water is poured upon it, which absorbs the salt. The earth is allowed to subside, upon which the water impregnated with salt is drawn off into another trough, and left to crystallize in the heat of the sun. The salt is packed in four-cornered bags of cow-hide, each containing from thirty to forty lbs. A plate of salt is valued at from twenty to forty rees; a sack at from 300 to 400. The annual produce of the salines exceeds 35,000 sacks. Salines nearly as productive are found at the sources of the Paraguay, in Matto Grosso; and considerable quantities of salt are manufactured on the shores of the northern provinces. Between the salt district and the hills saltpetre occurs in great quantities. Fifteen leagues above the Rio de Salitre, large caves are found in the limestone-rock, filled with black earth, which sometimes contains three fourths of its weight in saltpetre. This is washed out, and the water heated to a certain degree, in order that it may deposit the culinary salt; the saltpetre is then left to crystallize. A similar process is followed at Formigas, near the source of the S. Francisco.

Ship-building is diligently pursued at more than one station along the coast. The port of S. Francisco is the most southerly point at which the construction of vessels is carried on to any extent. Vessels of large size, and a number of small craft for coasters, are built here. The demand for ship-carpenters is always brisk. To the north of Bahia, on account of the reef, the ships built are generally of a small tonnage. Laranjeiras, Itapicuru, and Villa do Conde, build vessels capable of holding from 4000 to 8000 arrobas of lading. Pernambuco fits out a great number of small craft. The royal docks at Bahia are small, and few ships of war are built there; but such as are have the character of surpassing even the East Indian vessels in durability. Merchant ships are for the most part built at Tapagipe, about a league and a half to the north-east of the city. We have

Statistics. no trust-worthy account of the probable amount of capital invested in ship-building.

Whale-fishery. The whale-fishing is here in its appropriate place. The stations of this fishery are S. Catliarina, Itaparica, and Bahia. It is only pursued in small boats near the shore. The pans in which the blubber is boiled are small, and heated by common stoves. The receivers are extremely apt to collect dust and dirt of all kinds. Throughout Brazil, not above 100 fish, great and small, are taken in the course of a year. Each yields, on an average, from fourteen to eighteen pipas (150 gallons English each) of train oil; and the value of this oil, together with the whalebone, may amount to L.150. On the islands of the Solimoes (Upper Amazons) a considerable quantity of oil is yearly collected from the eggs of the turtle, which are dug up, broken in the boats, and left till the light oil separates and swims on the top. It is boiled and separated from the impurities, when it assumes the colour and consistence of lard. This product is deposited in earthen pots containing fifty or sixty pounds each. Of these more than 8000 are yearly prepared on the Amazons. The Madeira yields 1000. The drying and salting of fish is carried on to a considerable extent along the sea-coast, on the Amazons, and upon a large lake near the salines on the Rio de Francisco. A coarse kind of woollen cloth for home consumption is manufactured at S. Paulo. Hats are made at S. João d'el Rey. There is an establishment for the manufacture of arms in the town of S. Paulo; a powder-mill in the neighbourhood of Rio, and one of less importance in Minas. A coarse cotton cloth is woven in Goyaz, Maranhão, and Sergippe d'el Rey, used to clothe the slaves, or form bags for packing cotton. In S. Paulo, Goyaz, and Para, tanning is carried on to a small extent.

Commerce. Nothing serves better to convey a just notion of the state of trade in a nation than a knowledge of the state of its circulating medium, and the means of communication between one place and another. The sums of gold, annually paid into the Brazilian treasury under the designation of fifths, might afford ample materials for a metallic currency. The great quantities of bullion, however, annually shipped for Europe, for the East Indian and China trade, have counteracted the tendency of this arrangement. The amount of metallic currency even in Rio it has been found impossible to ascertain with any degree of accuracy, the drains occurring at such irregular intervals. Interest has been known to rise at once from twelve per cent., the average rate, to twenty or even twenty-two per cent. In Minas, the proprietors of the mines are in the habit of allowing their gold to remain at the mint, and take a receipt in exchange, which circulates freely through the whole of Brazil. The metallic currency in Minas Novas in 1818 did not amount to 80,000. At the salines on the Rio Francisco salt is used as a medium of exchange. In the interior the primitive mode of barter is still of frequent occurrence. Previous to 1808 a bank issuing notes was established in Rio by a company of the wealthiest merchants and capitalists. As the institution grew in wealth, it ventured to establish an insurance company, and to farm several of the regalia. Officers of state in the different provinces now began to deposit a part of their salaries in the bank, and rich landed proprietors their monied capital. In 1808 the bank was erected by royal charter into the bank of Brazil. Since that time it has taken the active share in financial arrangements, to which we have already alluded. The sums of money abstracted by the king when he quitted the country in 1821, and several underhand transactions, are believed to have materially shattered the funds of the bank; its notes nevertheless retain their credit, and circulate in every province of Brazil.

VOL. V.

Statistics. The intercourse between place and place in Brazil is effected in three different manners; along the coast by small coasting craft, drawing about ten feet of water; on the rivers by boats manned on an average with twelve rowers and a steersman, besides the supercargo; towards the embouchures of the rivers larger vessels are in use; on the dry land, along roads, or rather tracks, by means of troops of mules, for, except in Rio and the immediate vicinity, there are no wheel-carriages in Brazil. From Minas Novas to Rio Janeiro there are twelve troops, each of forty mules, with their negro attendants and guiding arriero, continually on the road, engaged in carrying cotton, and bringing back European produce in exchange. From S. João d'el Rey there are four such troops annually; and from other places the number is in proportion to the frequency of their intercourse. Merchants who do not choose to wait the appointed period, and travellers of all kinds who carry baggage along with them, must form a troop more or less numerous, according to their wants. The difficulty thus thrown in the way of the transport of many articles of commerce may easily be conceived. Even river carriage, on account of the numerous falls on most of the streams, is scarcely more convenient.

Brazil being as yet a young country, dependent for most necessities of manufacturing produce, and for all the luxuries of civilized life, upon other countries, the tendency of its internal trade is in a great measure determined by its foreign commerce. The ports, which, from favourable situation, convenience, and the quantity of capital accumulated in their neighbourhood, monopolize in a great measure the external trade of Brazil, are Rio Janeiro, Bahia, Recife the capital of Pernambuco, Maranhão, and Para.

Rio Janeiro, in addition to its own produce, draws its articles of consumpt and export from the southern provinces of Rio Grande, S. Catharina, and S. Paulo, from Minas Geraes, and from Porto Seguro. The raw produce of the former, wheat, hides (an annual average of 300,000), unrefined tallow, horns, horse-hair, and *charque* or jerked beef, are imported coastwise, giving employment to a hundred sail of coasters, which make the voyage thrice in the year, and carry in return rum, sugar, tobacco, cotton, and European goods of all descriptions, particularly English. The produce of S. Catharina, exclusively agricultural, has been enumerated above. Two thirds of the whole are exported, chiefly to Rio Janeiro. This trade gave employment in 1812 to 152 vessels, three-masters, brigs, smacks, &c. In 1813 the value of the goods exported from the province of S. Paulo was L.166,735. Of these, to the value of upwards of L.134,000 found their way by land-carriage to Rio Janeiro. The returns from that city in wine, beer, iron and hardware, glass and stoneware, tea, &c. were valued at L.161,670. The cotton trade from Minas Novas to Rio Janeiro gives constant employment to twelve troops of mules, each mule carrying eight arrobas, valued at L.1. 15s. the arroba. Great numbers of precious stones are exported from Minas Novas to Rio. The greater part of the gold melted in Minas Geraes finds its way to Rio: the exact sum cannot be ascertained, but merchants trading to the East Indies have been known to export bullion to the value of L.800,000 in one year. S. João d'el Rey (still within Minas Geraes) supplies Rio with mules, cattle, poultry, gold, lard, cheese, hats, and some cotton cloth, and receives in return woollen and cotton cloths from England and Portugal, hardware, wine, porter, &c. From Porto Seguro, Rio draws tobacco and fish, but to what amount we have no means of ascertaining. The following table shows the amount and value of the most important articles exported from Rio Janeiro in 1817.

Statistics.

Articles.	Quantity.	Value.
Sugar.....	680,000 arroba.	L.340,000
Coffee.....	298,999 arroba.	171,900
Cotton.....	520,000 arroba.	640,000
Hides.....	112,000	153,500
Tobacco.....	30,000 quint.	45,000

Besides these weightier articles, Rio de Janeiro exports considerable quantities of horns, horse-hair, and hides, train-oil, ipecacuanha, and dye-woods. The value of these minor articles may amount, one year with another, to L.400,000. The returns from Portugal and her colonies are made in wine, oil, vinegar, dried fish, hams, olives, brandy, leather, drugs, cloths, books, musical instruments, paper, gun-powder, earthenware, ropes, canvass, tar, pitch, steel, and shoes. Those from London, Liverpool, and the British colonies, consist of cotton and fine woollen cloths, porcelain and earthenware, iron, lead, copper, tin, anchors, cables, gun-powder, porter, cheese, salt-butter, and spirituous liquors. East India goods are imported direct or from Gibraltar. France sends articles of elegance and luxury, furniture, silks, books, liqueurs, paintings, mirrors, hats, oil, &c. Holland sends beer, glass, linen, and holland; North America grain, soap, spermaceti candles, biscuit, tar, leather, deals, potash, and coarse furniture. The northern nations of Europe send their staple wares. From Africa are imported gold dust, ivory, pepper, ebony, and slaves, the latter at an yearly average of upwards of 20,000. We have been unable to obtain exact lists of these returns; but their variety, and the value of the exports, indicate sufficiently the state of the foreign trade of Rio.

Bahia, as a depôt of home productions for the foreign trade, is perhaps of yet greater importance than Rio Janeiro. Three great roads lead to the interior; that over Conquista and Rio Pardo to Minas Geracs, that across the Rio de Contas to Matto Grosso and Goyaz, and that through Joazeiro to the interior of Pernambuco and Piahy. By the first come the cattle from Rio Grande do Sul; raw produce and live stock from S. Paulo to the value of L.6090; live stock, saltpetre, a small sum of gold, and cotton equal in quantity to that carried to Rio de Janeiro, from Minas Geraes. By the second come gold and precious stones from Goyaz and Matto Grosso, but to what amount we are unable to say. The latter province sends in addition deals, hides raw and tanned, brandy, mandioca, lard, and live stock, to the value of L.9000 per annum. From Pernambuco and Piahy the imports consist of cotton and cattle. The animal food consumed in Bahia, or exported, is collected from the interior of Brazil, in a circuit extending from Rio Grande do Sul to Piahy. Cotton is imported from a narrower range, including Minas, Pernambuco, and Piahy. The returns are made in negroes, wine, and foreign merchandise. The products of the coast are brought in boats to Bahia from a distance of thirty leagues on either side. The foreign trade is in some measure worthy the centre of such an immense district. In 1817, 2000 trading vessels visited Bahia, deducting coasters. The following table shows the principal exports in 1817, and their value.

Articles.	Quantity.	Value.
Sugar.....	1,200,000 arr.	L.600,000
Cotton.....	160,460 arr.	392,920
Tobacco, first quality.....	240,000 arr.	90,000
second.....	340,000 arr.	59,500
third.....	80,000 arr.	28,000
Hides.....	30,000	8,000
Coffee.....	10,000 arr.	13,750

The returns are essentially the same as at Rio. The proportion of European, North American, and African articles is greater; that of East Indian less. On an average, 12,000 negro slaves are annually imported into Bahia.

Recife has been styled by some the most important trading place in Brazil after Rio and Bahia; unfortunately our information respecting its trade is too meagre to enable us to judge. Of its home trade, we merely know that it is furnished with salt from the salines of Rio de Salitre, and that from its port is exported the cotton of Paraiba, Rio Grande de Norte, and Seara, in addition to that of Pernambuco. The average number of ships employed in the trade to North America and Europe is 150. The exports consist of cotton, sugar, molasses, rum, hides of goats and oxen, tobacco, cocoa-nuts, ipecacuanha, dye-woods, and Brazil-wood. The amount of cotton annually exported is 80,000 bags. The sugar of Pernambuco is nearly equal in quality to that of Bahia.

Respecting the intercourse between this city and the interior, or the less important towns on the coast, we have no means of judging. It appears that a brisk intercourse is kept up by means of small-craft (*Sumacas e Lanchas de Cabotagem*) with the harbours Vianna, Guimaraes, Turyassu, and Tutaia, within the province. Cotton is the staple of Maranhão; and Cachias, in the interior, is the centre of the cotton cultivation. The medium annual value of the exports from Maranhão between 1815 and 1820 amounted to L.770,151; of imports to L.710,295. In 1821 the value of the total exports amounted only to L.321,171. The most important articles were cotton to the value of L.239,654, and rice to the value of L.54,191. The whole was exported to Lisbon, Porto, Vianna, Figueiras, Liverpool, Havre de Grace, Rouen, and the United States of North America. Liverpool's share of the cotton alone is valued at L.150,165. The imports for the same year are valued at L.333,153. The principal article is flour, 54,793 arrobas from North America, 17,048 from Liverpool, and 9318 from different ports in Brazil. In the course of the year 200 foreign vessels entered the port, and 192 cleared out; 161 Brazilian vessels entered, and 157 cleared out. These numbers are exclusive of the small coasting vessels sailing from harbours within the province.

Para boasts of a greater variety of articles of export than any other city of Brazil, and with justice, for it reckons no less than forty. These are, in addition to what is called colonial produce, balsam of capaiva, sarsaparilla, Indian rubber, a variety of spices, and timber of different kinds. Of late horses have been added to the list, which are exported to the English colonies. The above articles, however, are the collective wealth of the Spanish provinces on the Upper Amazons, of the Rio Negro, and of the provinces of Goyaz and Matto Grosso. Para being the only harbour possessed by the country which is watered by the Amazons and its tributaries, it receives its superfluities, and sends the conveniences of Europe in return. In 1819 the value of the goods exported to Portugal was L.113,179, of those imported in return L.74,776. In the same year goods were exported to England to the value of L.73,871, and imported thence to the amount of L.76,660.

Brazilian Weights: 1 arroba = 32½ lbs. English; 1 quintal = 129½ lbs. English.—*Measures, Dry:* 1 alqueire = ½ bush. English; 1 maio = 17½ bush. English. *Liquid:* 1 canada = 2 galls. English; 1 pipa = 120 galls. English. *Longitudinal:* 5 varas = 6 yds. English; 27 covadas = 20 yds. English.

BRAZING, the soldering or joining two pieces of iron together by means of thin plates of brass, melted between the pieces that are to be joined. If the work be very fine, as when two leaves of a broken saw are to be brazed together, it is covered with pulverized borax, melted with water, that it may incorporate with the brass powder, which is added to it; then the piece is exposed to the fire without touching the coals, and heated till the brass is seen to run.

BRAZING is also the joining of two pieces of iron together by beating them hot, the one upon the other.

BRAZLAU, a town, the capital of the circle of the same name, in the Russian government of Podolia. It stands on the river Bug, in a very fertile district, and contains about 1200 inhabitants. Long. 28. 51. E. Lat. 48. 52. N.

BREACH, in a general sense, denotes a break or rupture in some part of a fence or inclosure, whether owing to time or violence. Inundations or overflows of lands are frequently owing to breaches in dikes or sea banks. Dagenham breach is famous; it was made in 1707, by a failure of the Thames wall in a very high tide. The force with which it burst in upon the neighbouring level tore up a large channel or passage for water a hundred yards wide, and in some places twenty feet deep, by which a multitude of subterraneous trees that had been buried many ages before were laid bare.

BREACH, in *Fortification*, is a gap or opening made in any part of the works of a fortress by the cannon or mines of the besiegers, with a view to an assault upon the place. To render the attack more difficult, the besieged sow the breach with crow-feet, stop it up with *chevaux de frise*, or retrench it by cutting traverses within. A practicable breach is that where men may mount and effect a lodgment, and it ought to be fifteen or twenty fathoms wide. The besiegers sometimes make their way to it by covering themselves with gabions, earth-bags, and the like; but in our army the practice has always been for storming parties to advance to the breach without any cover or protection, and to trust for success to their own daring and perseverance.

BREAD, a mass of dough kneaded and baked in an oven. See **BAKING**.

BREAD, ASSIZE OF. See **BAKING**.

BREAD-FRUIT. Among the more valuable products of the warmer climates and the fertile islands of the Southern Pacific Ocean, is to be ranked the bread-fruit, or *Artocarpus incisa* of botanists. Nature has favoured the tropical regions, and those countries in their vicinity, with inexhaustible quantities of the choicest vegetables, while the inhabitants of the north are restricted to shrivelled berries and meagre roots; and if they have obtained a supply, always precarious, of some of the finer fruits, it is the result of patience, skill, and industry.

Ever since Europeans frequented the eastern world in commercial enterprise, it is probable that they were acquainted with the bread-fruit. How, indeed, could its properties be unknown to Quiros, who visited Otaheite so long ago as the year 1606? Yet the English navigator Dampier seems to have been the first European whose notice was particularly directed towards it, during his circumnavigation in the year 1688; and he expresses himself in these words: "The bread-fruit, as we call it, grows on a large tree, as big and high as our largest apple trees. It hath a spreading head, full of branches and dark leaves. The fruit grows on the boughs like apples; it is as big as a penny-loaf when the wheat is at five shillings the bushel. It is of a round shape, and hath a thick tough rind. When the fruit is ripe it is yellow and soft, and the taste is sweet and pleasant. The natives of Guam use it for

bread. They gather it, when full grown, while it is green and hard; then they bake it in an oven, which scorseth the rind, and makes it black; but they scrape off the outside black crust, and there remains a tender thin crust; and the inside is soft, tender, and white, like the crumbs of a penny loaf. There is neither seed nor stone in the inside, but all of a firm substance like bread. It must be eaten new, for if it be kept above twenty-four hours it becomes dry and eats harsh and choky; but it is very pleasant before it is too stale. This fruit lasts in season eight months in the year, during which time the natives eat no other sort of food of bread kind. I did never see of this fruit any where but here (Guam). The natives told us that there is plenty of this fruit growing on the rest of the Ladrone Islands, and I did never hear of it anywhere else." The bread-fruit, however, is found in still greater profusion, and in equal perfection, on many of the groups of islands scattered throughout the Southern Pacific Ocean; nor is it confined to them exclusively, but their soil and climate seem to correspond more intimately with the conditions of its vegetation.

There are two leading species of this plant, which are Different characterized by the presence or absence of seeds; the species.

latter being the preferable kind, and that which is cultivated more carefully for its produce. The natives of the South Sea Islands maintain, however, that eight different species, or rather varieties, may be distinguished, and for which they have the respective names of Patteah, Eroroo, Awanna, Mi-re, Oree, Powerro, Appeere, Rowdeah. The leaf of the first, fourth, and eighth, differs from that of the rest; the fourth being more sinuated, and the eighth having a large broad leaf, not at all sinuated. In the first, also, the fruit is rather larger, and of a more oblong form, while in the last it is round, and not above half the size of the others. European observers, however, do not seem in general disposed to recognise these as essential distinctions, although they admit other varieties.

As Dampier observes, the bread-fruit is a large tree, growing to the height of forty feet or more. It is thick in the stem, and has a luxuriant foliage. The trunk is upright, the wood soft, smooth, and yellowish; and wherever the tree is wounded, a glutinous fluid exudes. The branches form an ample head, almost globular; the leaves are eighteen inches long and eleven broad, resembling those of the oak or the fig tree, from their deep sinuosities. The younger leaves, like all the more tender plants of the tree, are glutinous to the touch. The male flowers are among the upper leaves, and the female flowers at the ends of the twigs. But it is the fruit which constitutes the value of the plant, and this is a very large berry, according to botanists, with a reticulated surface, resembling a cocoa-nut or melon in size and form, nine inches in length. It is filled with a white farinaceous fibrous pulp, which becomes juicy and yellow when the fruit is ripe; and the edible portion lies between the skin, which is green, and a core in the centre, which is about an inch in diameter.

During a considerable portion of the year the bread-fruit affords the chief sustenance of the Society Islanders. It is prepared after different fashions, and its taste depends in a great measure on the mode of preparation. It is insipid, slightly sweet, somewhat resembling wheaten bread mixed with Jerusalem artichokes, and it has been compared to a cake made of flour, egg, sugar, milk, and butter. In general it is cut in several pieces, and roasted or baked in a hole made in the ground, which is paved round with large smooth stones; and then it resembles a boiled potato, not being so farinaceous as a good one, but more so than one of ordinary quality. The stones are previously heated by a fire kindled in the excavation,

Bread-fruit.

Used as food to a great extent.

Bread-fruit.

and the bread-fruit, being wrapped in a banana leaf, is laid upon them, and covered with leaves and hot stones. In Otaheite, and in the West Indian Islands, several dishes are made of it, either by thus baking it in an oven entire, when it is considered to equal or surpass any kind of bread, by adding water or the milk of the cocoa nut, by boiling it, or forming it into a paste. This last is accomplished by taking the fruit before it attains complete maturity, and laying it in heaps, closely covered up with leaves, when it undergoes fermentation, and becomes disagreeably sweet. The core being then drawn out, the fruit or pulp is thrown into a paved excavation, and the whole covered up with leaves, whereon heavy stones are laid: it thus undergoes a second fermentation, and becomes sour, after which it will suffer no change for a long time. A leaven may thus be formed of it, which is baked as occasion requires. In the island of Nukahiwa, an agreeable beverage can be obtained from it; and in the West Indies it can be baked like biscuit, and will keep nearly as long. The fruit is in the greatest perfection about a week before beginning to ripen, which is easily recognised by the skin changing to a brownish cast, and by small granulations formed of the juice. In the West Indies it is soft and yellow when ripe, and is in taste and smell like a very ripe melon. Hogs, dogs, and poultry then feed on it readily.

Besides this, the bread-fruit tree proper, there is one that has been long known in India and the eastern islands, of which the fruit contains from forty to a hundred farinaceous seeds, in appearance resembling chestnuts. These when roasted or boiled are more grateful to many persons than the bread-fruit, and the negroes are very fond of them. The external characters of the tree are scarcely to be distinguished from those of the other, and the chief distinction lies in the fruit, which attains nearly the size of that we have described, and is covered with prickles like a hedgehog. It grows from the seed with rapid vegetation, and attains larger dimensions than the proper bread-fruit tree.

Its other uses.

The natives of those islands producing this useful vegetable collect it with very little trouble; they have only to climb the tree and gather the fruit. Nor is nutriment the sole purpose to which it is converted; for they have a method of fabricating cloth from the bark, the leaves are substituted for towels, and the wood is employed in the construction of their boats and houses. A kind of cement and birdlime is also prepared by boiling the juice exuding from the bark in cocoa-nut oil.

Its cultivation.

It appears that there are other vegetables of this class, producing fruit of inferior quality, but on that account receiving less attention. The bread-fruit proper is of easy cultivation in its native soil. In some of the islands it seems an indigenous product, and springs from the root of old trees without any care; in others, it requires simply to be put into the earth. The trees flourish with the greatest luxuriance on rising grounds; and it has been remarked, that where the hills of the Sandwich Islands rise almost perpendicularly in a great variety of peaks, their steep declivities, and the deep valleys intervening, are covered with trees, among which the bread-fruit is particularly abundant. It has also been observed, that although we are accustomed to consider Otaheite as of the greatest fertility in this plant, the trees of the Sandwich Islands produce double the quantity of fruit. Though nearly of the same height, the branches begin to shoot out much lower from the trunk, and with greater luxuriance. In Otaheite, they are propagated by suckers from the root, which are best transplanted in wet weather, when the earth forms balls around them; then they are not liable to suffer from removal. This valuable plant is widely diffused in the southern and eastern isles, and it is generally

found throughout the Great Pacific Ocean. It grows on Amboyna, the Banda Islands, Timor, and the Ladrões; but it is more especially the object of care and cultivation in the Marquesas, and the Friendly and Society Islands, where it vegetates in uncommon luxuriance and profusion.

The great utility of the bread-fruit as an article of subsistence for mankind has, at different times, led to speculations on the possibility of naturalizing it in places where it is not of spontaneous growth. M. de Poivre, the philosophical governor of the Mauritius, succeeded in introducing it there, and in the Isle of Bourbon, whither it was conveyed by M. de Sonnerat, from Luçon, in the Philippine Islands. Being found in the greatest luxuriance under the same latitudes as the British West India Islands, and in a climate not dissimilar, government deemed the transmission of it thither, both as practicable without much difficulty, and as promising a future store of subsistence for the inhabitants. An expedition was therefore fitted out with particular care, under the command of Captain, then Lieutenant Bligh, who sailed in the *Bounty* store-ship for the South Seas in December 1787. This vessel was prepared so as to receive a great many bread-fruit and other plants, which would have proved a valuable acquisition to the colonists of the West Indies, and some of which were expected to succeed under the culture of the curious in Great Britain. The *Bounty* arrived in safety at Otaheite, the principal place of her destination, and took on board 1015 bread-fruit plants, besides a great variety of different species of other plants, and after remaining twenty-three weeks, which were busily occupied, set sail on the 4th of April 1789. But it is unnecessary to say more of the expedition, except that it was rendered totally abortive by a mutiny which ensued three weeks subsequently to its departure. The captain and eighteen adherents were barbarously turned adrift in an open boat, wherein they suffered incredible hardships, and, after a navigation of 3600 miles, reached the island of Timor, having lost only one of their number, who was murdered by the savages of an intermediate island. Notwithstanding the unfortunate result of this voyage, the object was still kept in view, and a new expedition planned with still greater precaution than the former; and it has been said that his late majesty, King George III. took a lively interest in conferring so important a benefit on a distant portion of his people. Captain Bligh having arrived in England, was appointed to the command of the *Providence* and *Assistance*, two vessels specially fitted out as before; and part of their complement consisted of two gardeners, to take the management of the plants collected. The vessels sailed in August 1791, reached Van Diemen's Land in February 1792, and anchored at Otaheite in February following. Here they remained above three months, and obtained even a greater store of plants than formerly; for there were now 1281 pots and tubs, whereas the first number of the bread-fruit trees, in 1789, did not exceed 887. Captain Bligh, in returning, made a dangerous voyage through Endeavour Straits, the exploring of which was part of his former instructions, and anchored at Coupang in the island of Timor, where he substituted many other plants for those that had died. He then sailed for the West Indies, and touching at St Helena, landed some bread-fruit plants, and took on board those of different species. The object of his voyage was at length completed by reaching the island of St Vincent's in January 1793, where he committed 544 plants, of which 333 were bread-fruit, to the care of Dr Anderson, superintendent of the botanical garden, and substituted for them 467 of different species, designed for his majesty's garden at Kew. In the next place, Captain Bligh landed 623 plants, of which 347 were bread-fruit, at Port Royal in the island of Ja-

Bread-fruit.

maica, and replaced them with a further collection for the king, with which he arrived in England on the 2d of August 1793. Five years and eight months had thus been occupied in accomplishing the desirable purpose of these two expeditions. But it belonged especially to Britain, by whom a familiar intercourse with the southern islanders was first opened up, to effect an object of so much importance.

Nevertheless, some have been found inclined to challenge the wisdom of so difficult and expensive an experiment; both because the expectations of those who looked for an inexhaustible source of subsistence were not speedily realized, and because the places best adapted for its culture already possess another vegetable, the plantain, which is much more grateful to the negroes, for whom the bread-fruit was principally designed. It has been argued that the bread-fruit tree requires considerable care in cultivation, that its progress to maturity is slow, though in Britain it would appear extremely rapid. Three years are required to reap the fruit; the plantain demands no care, while it produces its crop in fifteen months; thus giving it a decided preference in the opinion of the colonist, who is always impatient for a return. Further, it has been said, that wherever any vegetable, already relished by the inhabitants of a district, is completely established, they will always reject what they think less agreeable. These arguments have certainly had considerable weight; probably, however, from not duly appreciating the difficulties attendant on such an experiment as the naturalization of plants. But were we to take a retrospect of all the obstacles which have opposed the cultivation of many species of grain and fruits, at present not uncommon in Britain, it would be very evident that success has resulted only from the most patient and laborious attention. Positive conclusions on this subject are perhaps as yet premature.

In the year 1777 a premium was offered by the Society for the Encouragement of Arts and Manufactures, to any individuals who should bring the bread-fruit plant from the South Sea Islands in a state of vegetation to the West Indies, and the gold medal was awarded, in 1793, to Captain Bligh accordingly. That society, with the laudable design of promoting its culture, continued to offer further premiums for the greatest number of plants raised in the British settlements; and in consequence a silver medal was awarded to Dr Anderson, superintendent of the botanical garden at St Vincents in 1798; and, in 1802, the gold medal to the Honourable Joseph Robley, governor of the island of Tobago. From the course adopted by these two cultivators, the history of the bread-fruit has received much elucidation, and we shall comprise it in a few observations.

Mr Robley received three plants from Dr Anderson in June 1793, which he planted in very deep rich soil, and paid them every attention in hopes of procuring shoots. They flourished exceedingly, produced fruit in 1795, and continued to do so until autumn 1801, after which we have no notices respecting them. Being disappointed of obtaining suckers, Mr Robley applied to Dr Anderson, who advised him to lay bare some of the uppermost roots, and to wound them very deeply; and having followed these directions in October 1800, they almost immediately began to put forth shoots in abundance. In December, 120 fine plants were thus obtained, which Mr Robley placed in baskets containing about a gallon of good rich loose soil, and deposited in the shade in the vicinity of water. With this element also they were refreshed when the weather required it. Baskets were preferred to pots for the plants, from being lighter and more easily removed; likewise, because when deposited in the place

where they were ultimately to remain, the baskets would speedily rot, and not repress the growth of the plant, which would then extend its roots. European cultivators would do well to attend to the beneficial use of baskets; for it too often happens that a tender plant is wounded in removing it from a pot, or that the earth surrounding it is so deranged and displaced, that no subsequent care can preserve it from destruction. Encouraged by the successful issue of these previous experiments, Mr Robley prepared a point of land of loose sandy soil, bounded by a salt lagoon and the sea, for receiving a large plantation. When the tide filled, brackish water was to be found everywhere at the depth of two feet and a half from the surface; but it had been observed in some of the South Sea Islands, that bread-fruit trees grew in full vigour though brackish water bathed their roots, and the point was otherwise defended from the encroachments of the sea by an artificial bank. The land being ploughed and harrowed twice, was divided into beds stretching across from the sea to the lagoon; the beds were twenty-seven feet in breadth, and the plants put into the earth in the middle of each, and exactly at the distance of twenty-seven feet asunder; thus leaving a large space for their vegetation. Mr Robley's expectations were not disappointed. In August 1801 he had 153 plants in a flourishing condition; and, prosecuting the object still further, he had, in the course of the subsequent year, 371 on the point of land, of which no less than 319 plants were in a flourishing, and some of them in a productive state. He transmitted specimens of the fruit to England preserved in vinegar, as it will not keep above two days after being taken from the tree; as also of the dried leaves and blossom. Other correspondents, nearly about the same time, sent specimens of cakes made from the bread-fruit converted into flour, which were extremely well flavoured; and it seemed that a dry nutritious food, resembling tapioca in appearance and quality, might be prepared from it. The vegetation of this plant is very rapid. Ten of those committed to the care of Dr Anderson in 1793 were about two feet in height and half an inch in diameter; and he observed, that, in the year 1798, most of the trees in the botanical garden at St Vincents were above thirty feet in height, and the stem two feet above the ground was from three feet to three and a half in circumference. From the remarks he was enabled to make in this interval on the varieties of the tree in the botanical garden, it appeared that the fruit came out in succession during the greater part of the year, but less of it between November and March than at any other time. The number produced by a single tree was very great, being often in clusters of five and six, and bending the lower branches to the ground. According to the different varieties, the fruit was of various shapes and sizes, weighing from four to ten pounds, some smooth, others rough and tuberculated. When taken from the tree before maturity, the juice appeared of the consistence and colour of milk, and in taste somewhat similar. It issued for above ten minutes in an uninterrupted stream, and thickened into a glutinous and adhesive substance. Three months were required to bring the fruit to perfection, which, as above remarked, is about a week before it begins to ripen. Besides the Otahaitan bread-fruit, Captain Bligh left some of the East India bread-fruit in the botanical garden. But this proved of infinitely inferior quality, and a very indifferent substitute for it. It was ill-shaped, of a soft pulpy substance, and, like the other, wanting seeds, and propagating itself by suckers springing from the root.

A species of fruit bearing considerable analogy to those above described, is found on the Nicobar Islands, but we are unacquainted with the degree of attention it has re-

fruit of the
Nicobar
Islands.

ceived, either for the purpose of illustrating its natural history, or for economical uses. It is not less beneficial, however, to the natives. The tree producing this fruit vegetates promiscuously with others in the woods, but prefers a humid soil. Its trunk is straight, thirty or thirty-five feet in height, and from ten inches to two feet in circumference. The roots spring from it above the surface, and do not penetrate deep into the earth. The leaves are disposed like the large calyx of a flower; they are three feet long and four inches broad, of a dark green hue and tenacious substance. A long time elapses before the tree produces fruit, not less than about the period of human life. It then forms at the bottom of the leaves, from which it proceeds as it is enlarged, and, when nearly ripe, its colour changes from green to yellowish. This is the proper period for gathering it, when its weight is between thirty and forty pounds. The exterior surface is cut off, and the fruit is boiled in earthen pots covered with leaves, during several hours, on a slow fire; when, becoming soft and friable, the preparation is sufficient, and the fruit is then exposed to the air, and is next formed into a mass not unlike maize either in taste or colour. It may be preserved for a long time, but exposure to the atmosphere occasions acidity. The plant producing this fruit, however, is not of the same genus as those above described, although its fruit is converted to similar uses, but is rather a kind of palm, which it might be useful to naturalize in the eastern possessions of Britain. (N. N.)

BREAD, SACRAMENTAL, in the Protestant churches, is common leavened bread, in conformity to the ancient practice. In the Roman Catholic mass, azymous or unleavened bread is used, particularly in the Gallican church, where a sort is provided for this purpose, called *pain à chanter*, made of the purest wheaten flour pressed between two iron plates graven like wafer-moulds, and rubbed with white wax to prevent the paste from sticking. The Greeks observe divers ceremonies in making the eucharist bread. The Abyssinians have an apartment in their churches allotted for this service, being a kind of sacristy. Sirmond, in his disquisition on azymous bread, shows, from the council of Toledo, that anciently there were as many ceremonies used in the Latin church in the preparation of the unleavened bread as are still retained in the eastern churches.

Ecclesiastical writers enumerate other species of bread allotted for purposes of religion; as, *first*, *Kalendarius*, that anciently offered to the priest at the kalends; *secondly*, *Prebendarius*, the same with *capitularis*, that distributed daily to each prebendary or canon; *thirdly*, *Benedictus*, that usually given to catechumens before baptism, instead of the eucharist bread, which they were incapable of partaking of. The *panis benedictus* was called also *panagium* and *eulogium*, being a sort of bread blessed and consecrated by the priest, by which the catechumens were prepared for the reception of the body of Christ. The same was used afterwards, not only by catechumens, but by believers themselves, as a token of their mutual communion and friendship. Its origin is dated from the seventh century, at the council at Nantes. In the Gallican church we still find *panis benedictus*, *pain benit*, used for that offered for benediction, and afterwards distributed to pious persons who attend divine service in chapels. *Fourthly*, Consecrated bread is a piece of wax, paste, or even earth, over which several ceremonies have been performed with benedictions and other rites, to be sent in an *Agnus Dei* or relic-box, and presented for veneration. *Fifthly*, with regard to unleavened bread, *panis azymus*, the Jews eat no other during their passover; and exact search was made in every house to see that no leavened bread had been left. The usage was introduced in memory of their hasty de-

parture from Egypt, when they had not leisure to bake leavened bread. *Lastly*, shew-bread was that offered to God every Sabbath-day, being placed on the golden table in the holy of holies.

BREADALBANE, or BRAIDALBIN, a district of Scotland, in the western part of Perthshire, about thirty-three miles in length by thirty-one in breadth. It is mountainous, and for the most part unproductive. The hills, however, afford pasture for large flocks of sheep, and some of the valleys are cultivated, though not extensively, whilst others are nothing but mosses of peat and heath. At one extremity lies Loch Lyon, from which the river Lyon issues, and, flowing in a sinuous course, discharges itself into the Tay. In the centre of the district lies Loch Tay, which is about sixteen miles in length, and is surrounded by natural scenery of great beauty and splendour. The country abounds in limestone; and several metals, such as lead and copper, are also found. There is not a town in the district, and the only villages worthy of mention are Kenmore, Killin, and Clifton. It is now traversed by several good roads. In addition to the avocations of agriculture and the breeding of cattle, a part of the inhabitants during summer occupy themselves in collecting a species of lichen from among the rocks, which is used by dyers. The Earl of Breadalbane is the chief proprietor, whose seat is Taymouth, near Kenmore.

BREAK, in a general sense, signifies to divide a thing into several parts with violence. In the art of war, to *break ground* is to open the trenches before a place. Among sportsmen, to *break a horse* in trotting, is to make him light upon the hand in trotting, in order to make him fit for a gallop. To *break a horse* for hunting, is to supple him, to make him take the habit of running.

BREAKERS, a name given by sailors to those billows that break violently over rocks lying under the surface of the sea. They are distinguished both by their appearance and sound, as they cover that part of the sea with a perpetual foam, and produce a hoarse and terrible roaring, very different from the sound which the waves usually produce in a deeper bottom. When a ship is unhappily driven among breakers, it is hardly possible to save her.

BREAKWATER is any obstruction of wood, stone, or other material, as a boom or raft of wood, sunken vessels, &c., placed before the entrance of a port or harbour, or any projection from the land into the sea, as a pier, mole, or jetty, so placed as to break the force of the waves, and prevent their action on ships and vessels lying at anchor within them. Thus the piers of the ancient Piræus and of Rhodes; the moles of Naples, Genoa, and Castellamare; the piers of Ramsgate, Margate, Folkstone, Howth, and the wooden dike de Richelieu, thrown across the port of Rochelle, may all be denominated *Breakwaters*. In French it is sometimes called *Battre d'Eau*; a name which appears to have been applied to the mole at Tangier, a work commenced in 1763 under the direction of Lord Tiviot, Sir J. Lawson, and Sir Hugh Cholmley, and finished, or rather discontinued, in 1776, after having cost this nation the sum of L.243,897. 5s. 4½d. The term *Breakwater*, however, has of late years been considered as more peculiarly appropriate to large insulated dikes of stone, whether of regular masonry or sunk promiscuously in rough masses, so placed as to form an artificial island across the mouth of an open roadstead, and thereby, from obstructing and breaking the waves of the sea, to convert a dangerous anchorage into a safe and commodious harbour for the reception of ships of war or merchantmen.

Of this description of dike for creating an artificial harbour on a grand scale, fit for the reception of ships of war of the largest class, there are two remarkable examples in the breakwater of Cherbourg and that of Plymouth.

BREAKWATER OF CHERBOURG. In M. de Cessart's *Description des Travaux Hydrauliques*, will be found a very minute and laborious detail of all the preparatory operations, the progress, and the expense of constructing the breakwater of Cherbourg, up to the period of the Revolution. But the history of this great undertaking is summarily stated in a report made to the National Assembly in 1791, by M. de Curt, in the name of its Committee of Marine, concerning the marine establishment of Cherbourg.

It had always been a source of considerable annoyance to the French (and more particularly since the demolition of the works and basin of Dunkirk, which cost them more regret than the useless and expensive projects for that port ever could be worth), that while the whole line of their coast bordering on the English channel presented only sandy shores with shallow water, or an iron-bound coast bristled with rocks, nature had lavished on their "eternal rival" of the opposite coast, the incalculable advantages of a succession of deep and commodious harbours, or of safe and extensive roadsteads, inviting their possessors to commerce and navigation, and placing in their grasp "the sceptre and the sovereignty of the seas." M. Curt observes, that "the misfortunes of La Hogue, which all the talents of Tourville could not prevent, taught Louis XIV. that, in completing the defence of his frontiers by land, he had too much neglected his frontiers on the sea; that this great prince, however, profiting by experience, soon discovered that England owed the superiority of her marine to the military establishments which she possessed in the Channel." With a view of securing to France similar advantages, the Maréchal de Vauban was directed to visit the coasts of Normandy, for the purpose of adopting measures for placing in security against hostile attacks all such bays, harbours, and inlets, as were favourable for the disembarkation of troops; and to furnish plans of such works as he might judge to be necessary, not only for military, but for naval purposes. Among other projects, he reported that the roadstead of Cherbourg possessed the means of attack, of defence, and of protection; that it was very capable of exerting an influence on maritime war, and in their commercial relations with the northern powers; that it was the spot on which the head-quarters should be established on the coast of the Channel; and, in short, that it was a central advanced post with regard to England. He moreover reported, that it might be made a port for the safe retreat of a squadron crippled by stormy weather, or beaten by an enemy, or even for the reception of a victorious fleet with its prizes. By thus converting the present exposed roadstead of Cherbourg into a safe and protected anchorage for a fleet of men of war, France, he said, would be able to watch the motions of England, to oblige her at all times to keep a corresponding fleet in the Channel, and to menace her shores with invasion, of which she at all times stood so much in dread.

Opinions, however, being divided between the advantages of La Hogue and Cherbourg, Louis XVI., immediately after the conclusion of the American war, issued his directions to M. de Castries, secretary of state for the marine, to appoint a special commission to consider and report which of these two roadsteads combined the most advantages, and was in all respects preferable for constructing a port and naval arsenal capable of receiving and equipping from eighty to one hundred vessels of war of different descriptions. The commissioners had little hesitation in deciding upon Cherbourg, because, by means of a breakwater, it would be capable not only of admitting a fleet to ride securely at anchor when thus sheltered from the sea, but also of affording them protection against any

attempt of an enemy. It was added, that Cherbourg was an admirable place for watching Portsmouth; without appearing to have once recollected what an excellent anchorage Spithead was for watching Cherbourg.

Directions were accordingly given to M. de Caux, commanding officer of engineers at Cherbourg, to commence, as a preparatory measure, with the construction of a fort on the island of Peleé, and another on Du Homet, according to plans given in by Vauban in 1679. By these works the roadstead would be flanked on the right and left. The interval, however, being found too great to afford sufficient protection to all the ships that might require to be anchored in the roadstead, M. de Caux presented a plan to the minister at war for constructing an intermediate fort in the sea, which should be casemated, and sufficiently large to contain all the buildings necessary for a garrison. The surrounding walls were proposed to be sunk in caissons of 6000 feet square at the base, and fifty-two feet in height. The top of the platform was to be eighty feet above the bottom of the sea, and the area of its surface 1000 square toises. This plan, however, was not considered as calculated to afford sufficient shelter to a fleet from the winds and waves, and new projects were called for by the government.

In 1777 M. de la Bretonnière, capitaine de vaisseau, one of the commissioners who had been named to report on the comparative merits of the two roadsteads of Cherbourg and La Hogue, had addressed a memorial to the minister of marine, in which he expatiated at great length on the numerous advantages held out by the former, and particularly with regard to the security of the anchorage. He proposed to construct, at the distance of a league in the sea, a stone dike of 2000 toises in length, leaving three open passages into the roadstead it was intending to cover, one in the middle, and one at each extremity. This dike, like that which was sunk before Rochelle, was proposed to have as its nucleus a number of ships filled with masonry, floated off and sunk in proper situations, and afterwards to be cased with large sunken stones to the height of fifty feet above the bottom of the sea. The reason assigned for sinking the stone vessels was the supposition, that an under current might cause so much motion at the bottom of the sea as would derange the level, and work away the loose stones; so little appears at that time to have been known of the increasing tranquillity of the waves of the sea in proportion to the increasing depth of water.

On this plan the commissioners observed, 1. That in order to construct a dike of 2000 toises in length, with sloping sides proportioned to its height, there would be required so great a number of old ships as could hardly be collected in all France in less than ten years; and if purchased from foreigners, the expense would be enormous. 2. That the assembling and employing the necessary number of seamen would be next to impossible, but, if possible, highly impolitic, when, just at the close of a maritime war, commerce felt a pressing want of their services; whereas it might be practicable, and would be advantageous, to employ the military for some time before disbanding them. 3. That no comparison would hold good between the roadstead of Cherbourg, with an opening to the sea of 3600 toises, and a depth of forty to forty-two feet of water at the lowest ebb, and the closing up of the entrance of the port of Rochelle, which is only 740 toises in length, and the depth of water only five or six toises. 4. That the upper part of the projected dike, being exposed to the violent action of the sea, the stability of that part could not be depended on; and besides, a dike covered at high spring-tides with eighteen feet water would not fulfil the two indispensable conditions,—smooth water, and protection against an enemy. These arguments were deemed con-

Break-water.

Break-water.

clusive, and the plan of M. de la Bretonnière was abandoned.

In 1781 M. de Cessart, inspector-general of bridges and embankments, received directions to prepare a plan that should cover a fleet of from 80 to 100 ships of war in the roadstead of Cherbourg from the attack of an enemy, and protect them against the elements. M. de Cessart was fully aware, that to raise a barrier in front of this roadstead, and in the middle of the sea, capable of resisting the impetuosity of the waves, and repelling the enterprises of the enemy, was no easy task. "Nothing," says he, "that I had ever performed, or that I had ever read of in ancient or modern history, appeared to me to be worthy of being placed in comparison with the grandeur of this project." He suggested, as the preferable and only mode of answering the purpose of producing smooth water in the roadstead, that, instead of one continued dike or mole, a number of large masses, separated from each other, of a circular form, with an elevation greatly inclined, should be substituted; in short, a series of truncated cones, which, touching each other at their bases, might present to the sea at the surface alternate obstacles and openings, and thus interrupt and break down the waves previous to their entering the harbour. He also considered that, as these openings at the surface would not exceed seventy-two feet, a sufficient barrier would be formed against the passage of an enemy's vessel; and that, if necessary, in time of war it might be rendered still more secure by placing strong chains of iron across the intervals. It was proposed to construct these conical caissons of wood, the number of which, to cover a front of 2000 toises, would amount to ninety, which, at 360,000 livres for each cone, would cause a total expense of 32,400,000 for the whole. The number, however, was afterwards reduced to sixty-four, and the time estimated for completing the work thirteen years. Each cone was to be 150 feet in diameter at the base, and sixty feet in diameter at the top, and from sixty to seventy feet in height, the depth of water at spring tides in the line in which they were intended to be sunk varying from about fifty-six to seventy feet. They were proposed to be sunk without any bottoms in them, by which the upward resistance of the water, acting on a base whose surface was equal to 17,678 square feet, would be avoided. The caissons, floated off by casks attached to their inner and outer circumference, being towed to the spot where they were destined to be sunk, were then to be filled with stones to the tops, and left for a while to settle; after which the upper part, commencing with the line of low water, was to be built with masonry laid in pozzolana, and encased with stones of granite.

This plan of a stone dike or breakwater being laid in detail before the minister of marine, it was deemed proper, on a subject so entirely novel, and of such great national importance, to consult the ablest men in France before any steps should be taken for carrying it into execution. The details were accordingly submitted to the four commissioners, M. de Borda, a naval officer and member of the Academy of Sciences; M. de Fleurieu, capitaine de vaisseau, and director of ports and naval arsenals, afterwards minister of marine; M. Peronnet, member of the Academy of Sciences, chief engineer of bridges and embankments; and M. de Chezy, inspector and director of the school of engineers. They recommended that, in the first instance, an experimental cone should be constructed and floated off. Instead, however, of sixty feet in height, the cone made at Havre was only thirty-six feet; the circumference of its base 472 feet, and having a slope of sixty degrees; the upper circumference was 339 feet. Within the exterior cone, at the distance of five feet ten inches from it, was an interior and concentric cone, bound

together by beams of wood pointing to the common centre, each being the section of the radius. The frame of each cone was composed of eighty large upright beams, twenty-four feet long and one foot square. On these were erected eighty more, of fourteen feet in length, making in the whole 320 of these large uprights; the machine was then planked, hooped, and firmly fixed together with iron bolts.

The cone at Havre being completed, the next operation was to tow it off to the particular spot where it was to be sunk. Being open at the bottom, it was found necessary to attach to the lower circumference 284 large casks, part to the exterior and part to the interior cone; besides fifty casks, attached by lines of equal lengths, from the bottom of the inner circle, to float towards the centre, and thus assist in keeping it upright and steady. It was easy enough, by these means, to float off a vessel of this kind. M. de Cessart observes, that the force of 7200 pounds produced by a capstan, was found sufficient to draw it on the water to a distance equal to the length of its own diameter, or about twenty-five toises, in two minutes.

"The success of the experiment made at Havre," says M. Curt, "had inspired such veneration for the conical caissons, that those persons who had been most disposed to object to the plan were now obliged to be silent." The result of the experiment at once decided the government to commence operations at Cherbourg. M. de Cessart was appointed director of the works, with four engineers to assist him. A permanent council, consisting of commanders in chief, directors, engineers, &c. was ordered to reside for six summer months at Cherbourg, and the other six in Paris; and a considerable body of troops were marched down to the neighbourhood, to furnish a competent number of artificers and labourers, to be employed on this great national undertaking.

In 1783 the buildings were commenced for lodging the principal officers of the civil and military departments, and their respective establishments; a naval yard was marked out and inclosed; roads of communication were opened with the forts; and at Becquet, about a league to the eastward of Cherbourg, a small harbour was dug out for the reception of about eighty vessels, which were to be employed in transporting the stones from thence by sea.

On the 6th June 1784 the first cone was floated off and sunk, and the second on the 7th July following, in presence of 10,000 spectators, assembled on the shores and quays of Cherbourg; but before the cavity of the latter could be filled with stones, a storm, in the month of August, which continued five days, entirely demolished the upper part of this cone. In the course of this summer the quantity of stones sunk within the cavities of the two cones, outside their bases, and in the intermediate space, amounted to 4600 cubic toises, or about 65,000 tons.

In 1785 three more cones were completed and sunk at irregular intervals; and, at the end of that year, the quantity sunk amounted to 17,767 cubic toises, or about 250,000 tons. In 1786 five additional cones were completed and sunk, one of them in presence of the king; and the quantity of stones thrown within them, and deposited on the dike connecting the cones, amounted, at the end of this year, to 42,862 cubic toises, or 600,000 tons. In 1787 five more cones were sunk and filled with stones, making, in the whole, fifteen; and the distance between the first and fifteenth cone was 1203 toises, and the quantity of stones deposited within these cones and the connecting dike, at the end of this year, amounted to 71,585 cubic toises, or more than 1,000,000 tons. The violent gales of wind that are frequent in November and December carried away all the upper parts of the five

cones which were sunk this year. In 1788 three more were sunk, but the upper parts of the first two were carried away as the others had been; the height of the third was, therefore, reduced, so as to be, when sunk, on a level with low water; but this cone was upset and soon went to pieces.

The enormous expense, and the delay that had been occasioned, in completing and sinking these eighteen cones, exhausted the patience of the government, so that in the following year, 1789, it caused the three cones, then on the building slips, to be sold for whatever they would fetch.

The total quantity of stone that was sunk within the cones, and on the intermediate dike, from the year 1784 to the end of December 1790, being seven years, amounted to 373,359 cubic toises, or about 5,300,000 tons.

These eighteen cones being sunk at irregular distances from each other, some being 25 toises, and others 300 toises from centre to centre, occupied a line of 1950 toises in length. The distance of the first cone from the island Pelée, on the east, was 510, and of the eighteenth, to Fort Querqueville, on the west, 1200 toises; so that the whole entrance or opening of the roadstead of Cherbourg was originally 3660 toises, more than one-half of which was now imperfectly covered by the breakwater.

The expense of this great undertaking was not, we suspect, accurately known, and could not, probably, be ascertained. M. de Cessart estimates the eighteen cones alone at 6,231,407 livres, or about L.260,000; and the total expense incurred between the 1st of April 1783 and the 1st January 1791, he states as under:

	Livres.	
The value of the materials of the cones..	2,462,369	9 6
The value of the workmanship.....	1,560,560	9 9
The conveyance and sinking of stones..	14,880,074	2 5
Incidental expenses for buildings, magazines, &c.....	2,359,489	5 0
Contingent expenses	395,926	13 4

Making the general total.....21,658,420 0 0 or L.900,000 sterling. In this estimate the extra pay to the troops and seamen employed would not appear to be included; for M. de Curt, in his report to the national assembly, states the total expense to have amounted to 32,000,000 livres, or L.1,300,000 sterling; and that a farther sum would be required of 879,648 livres, to bring the top of the dike to an uniform height, namely, a little above the level of the surface at low water of ordinary tides.

The number of people employed was prodigious. To enable M. de Cessart to complete and sink five cones a year, he found it necessary to employ 250 carpenters, 30 blacksmiths, 200 stone-hewers, and 200 masons; in all 680 artificers. The number of quarrymen and others employed in transporting 174,720 cubic toises of stone for the 64 cones originally intended, or 13,650 yearly, was estimated at 400 workmen, 100 horses, 30 drivers, 24 chasses-marées, each carrying seven cubic toises, or about 98 tons, with 100 seamen; making an aggregate for this service of 526 men, and for the whole operation from 1200 to 1500 artificers and labourers, to which were actually superadded about 3000 soldiers.

A very considerable part of the expense might have been saved by dispensing altogether with the cones, all of which burst, as might have been expected, from the superincumbent weight of a deep column of water pressing the stones within against their sides. The ninth cone, which was sunk in 1786, went to pieces in 1800, after standing fourteen years; another reached the duration of five years; six remained on an average about four years; and all the rest went in pieces within a year from the time of their being sunk.

VOL. V.

The failure of the cones, and the breaking out of the Revolution, put an entire stop, for some time, to all operations at Cherbourg. The attention, however, of the national assembly was speedily called to what they considered to be an object of great national importance. In 1791 they directed their committee for the marine to make out a detailed report of the operations that had already been carried on. On this report being given in by M. de Curt, in the name of the committee, it was read and approved by the assembly, and funds to a certain extent decreed, to complete the undertaking on a new plan, proposed by M. de Cessart. The principal feature of this plan was that of casing over the surface of the dike as it then stood with large blocks of stone, and of carrying the height of the breakwater along the whole of its extent, so far above the high-water mark of spring tides as to render it capable of receiving batteries on the summit, at the middle, and at the two extremities.

The slope of the side next to the roadstead was found on examination to sustain itself unaltered at an angle of forty-five degrees, but the slope on the side next to the sea, whose base was three for one of height, had given way to the depth of fourteen feet below the low-water mark; and the materials being composed of small stones, were washed away, and had formed themselves into a prolonged slope of one foot only in height for ten feet of base, which was therefore concluded to be the natural slope made by the sea when acting upon a shingly shore; a conclusion, however, too vague to be correct, as the slope occasioned by the action of the sea must depend on the nature of the materials against which it acts, and the force and direction of the acting power. A sandy beach, for instance, has invariably the most gradual slope, gravel the next, shingles the next, and large masses of rock or stone the most precipitous. At the present time the stones of the breakwater, by constant friction, have worn away the sharp angles, and it has been found that the base on the side next to the sea is on the average fully eleven for one of perpendicular height.

It was proposed, therefore, to cover the side with a coating of stone twelve feet thick, to consist of blocks of twelve, fifteen, twenty, and thirty cubic feet, or from one to two tons each, which casing was to be carried to the height of twelve feet above the high-water mark of the highest spring-tides; the size of the stones to increase towards the summit, so as to be capable of resisting the percussion of the waves, which is there the strongest. It was calculated that this covering of twelve feet thick on both sides would require for each toise in length seventy cubic toises of stone, and that the whole length of the dike would consequently require 136,500 cubic toises, which, by deducting for the vacant spaces between the stones, would be reduced to 113,750 cubic toises of stone, or about one million and a half of tons. It was further calculated, that the expense of quarrying, the transport to the quays, the loading, conveyance, and discharging machinery, together with the commissioners, clerks, &c. would cost for each cubic toise deposited on the dike the sum of fifty-five livres, which for 113,750 cubic toises would amount to 6,256,250 livres, and, adding for contingencies 600,000 livres, the total estimate amounted to 6,856,250 livres.

The machinery employed for thus casing the breakwater may be seen in Plate CXXVIII., in which fig. 4 represents a section of a lighter on which it is erected.

AZX is an elevated deck or platform.

Y, three rollers of six inches diameter.

TK, two beams or sheers, moving on trunnions in grooves at T.

S, hooks to hold the sheers at the proper angle of inclination.

Break-water.

L, the axle of the windlass or wheels B, round which the rope of the pulleys passes. The wheels are 12 feet in diameter.

Fig. 5, a chasse-marée laden with blocks of stone.

E, the block and its hook laying hold of an iron chain round a stone.

F, the stone hoisted to the platform AZ (fig. 4), when the brace is unhooked at S; the hoisting continued until the summit K of the sheers is brought to V, when they rest against the frame which supports the windlass; the stone F is then lowered upon the rollers as at M, from whence it is pushed forward by men to the inclined plane, off which it is rolled into the water upon the side of the dike.

It was calculated that, by employing a certain number of these machines, 34,090 toises might be deposited in one year, reckoning only six working months, or 5682 toises per month, or that 487 superficial toises of the dike might be covered in one season, and the whole completed in four years. Very little progress, however, had been made at the commencement of the war in 1803. At that period the centre of the dike only had been brought above the high-water mark, in which was placed a battery and a small garrison of soldiers, the whole of which were swept away by a heavy sea, occasioned by a tremendous gale of wind in the year 1809, when all the buildings which had been erected on this part of the breakwater, the men, women, and children which composed the garrison, together with several workmen, were washed away; at the same time two sloops of war in the roadstead were driven on shore and dashed in pieces. This disaster was such as might have been expected. The effect of sinking large stones upon the small ones, already rounded by constant attrition, could not be otherwise; the latter acting as so many rollers, carried out the former even beyond the extremity of the base, to which the breakwater had naturally been brought by the action of the sea.

At present small spots only are visible above the surface of the sea at low water of spring-tides, and nowhere such spots exceed three feet in height; the intermediate spaces are from three to fifteen feet below the surface; and, taking the average, the whole dike from one end to the other may be about four feet below the surface of low water at the spring-tides. Near the middle, however, there is about 100 yards where the height rises to eighteen or twenty feet above high water, but it exhibits only a shapeless mass of ruins. In one spot a large heap of stones has been accumulated, as if to try how much weight might safely be trusted upon it, before the attempt be made to rebuild the fort. The largest of the stones in this mass may be about four tons, and they descend to the size of 200 or 300 pounds.

Of the remainder of the dike very few parts are visible at low water; and at this moment the greater part is four feet below the surface of low water. It is sufficiently high, however, to break the force of the waves, and to make the port of Cherbourg a safe anchorage in some winds for about forty sail of the line.

On the renewal of the war after the rupture of the treaty of Amiens, Bonaparte began to bestow a greater share of attention on the navy of France; and though for a time the unparalleled victory of Trafalgar checked his efforts, it did not induce him to abandon them. His plans were vast, and at the period of his fall were in rapid progress towards their completion. He had determined on a fleet of 200 sail of the line, and the noble port of Antwerp gave him every facility for ship-building. For the better security in forming a junction of his two great fleets of Brest and Antwerp, Cherbourg now became more valuable as a convenient port of retreat in case of acci-

dent; but it had no dock-yard, nor means of giving to a ship a large refit or repair. He might have thought too, as we believe most of our naval officers do, that a fleet of ships riding at anchor behind the breakwater are easily attackable by fire-ships, as the same wind which carries a vessel in at one entrance will carry her out at the other, and the course would lie directly through the centre of the fleet at anchor. Besides, it might be possible, in certain winds, under the lee of the centre part of the breakwater, to bombard a fleet at anchor in the roadstead within it.

He determined, therefore, to establish a large dock-yard at Cherbourg, not merely for repairing, but also for the construction of the largest class of ships of war; to dig a basin that should contain fifty or sixty sail of the line; to construct dry-docks and slips for building and repairing; and to make it a naval port of the first rank. In 1813 this basin was completed at an expense, as Bonaparte is said to have asserted when on board the *Northumberland*, and which has since been confirmed, of £3,000,000 sterling. A wet-dock of the same magnitude communicating with it was then begun.

The only description that we have been able to find in print of this great work, which took ten years in carrying into execution, is contained in a short letter from M. Pierre-Aimé Lair, secretary to the Society of Agriculture and Commerce of Caen, who was present at the ceremony of opening and consecrating the great basin, in presence of the Empress Maria Louisa, on the 27th August 1813. He describes this basin as excavated out of a rock of granite schist, or gneiss, the density and hardness of which increased as the workmen descended from the surface. He compares it to an immense trough dug out of a single stone, and capable of containing many millions of cubic feet of water. We now know, however, that M. Lair is mistaken; that it is not one mass of rock, but rock and gravel mixed; that the whole of the sides are cased with a well-constructed wall of red granite; and that a noble quay, built of the same material, and extending between the two forts of Galet and Homet, separates the basin and wet-dock from the sea.

The dimensions of the new basin he states to be about 900 feet in length by 720 in width, and the average depth fifty-five feet from the edge of the quay; and as this edge is five feet above the high water mark of the equinoctial spring-tides, the depth of water in the basin is then fifty feet, and the mass of water, after making allowance for a slope of the solid sides inward in an angle of forty-five degrees from the height of about twenty-five feet, amounts to about thirty millions of cubic feet; and that it is calculated to contain about thirty sail of the line. We have reason to think that it is considerably larger, about 1000 feet by 770 feet, and consequently contains a surface of about eighteen acres, which, at three per acre, will contain fifty-four sail of the line, and the adjoining wet-dock, when finished, an equal number. The dike or breakwater seems to be abandoned, the works having long been stopped, and the stone vessels going rapidly to decay. The French officers say indeed that it has occasioned the roadstead to become shallower, by the deposition of sand that has taken place.

The entrance canal leading from the outer harbour into the basin is at right angles to the latter, and its direction east-north-east. Its dimensions are as under:—

	Feet. In.
Width between the two moles in the direction of their axis.....	196 8
Width at its opening into the basin.....	308 8
Length from the axis of the moles or piers to the line of wall forming the side of the basin.....	274 0

ak-
er. The basin, having no gates, is said to have been excavated to the depth of nine feet below the bottom of the canal; the former having, as before mentioned, fifty feet water, and the latter only forty-one at high spring-tides, which, as they ebb twenty feet, would leave only twenty-one feet in the passage or canal at low water. This inequality, we presume, is intended to keep the ships afloat in the basin at low water, when the depth in the canal is not sufficient for that purpose; but after so much expense incurred in digging the basin, one would suppose a little more might have been expended in digging the canal to the same depth, so as to let ships pass into and out of the basin in all states of the tide; an advantage of the utmost importance for speedily securing the ships in the basin, when in danger of an attack from the enemy in the roadstead, or for speedily putting to sea and escaping the vigilance of a blockading squadron. No reason is assigned for leaving the basin without gates; but we suspect that M. Lair is again mistaken, and that the passage has depth of water sufficient for ships of the largest class to run into the basin at all times of the tide. But even here they do not lie in safety; for the wide entrance facing the north-east is covered only in that direction by the isle of Peleé, so that the water in the basin partakes of the swell in the road, which is sometimes so great as to make it necessary to apply ten or twelve cables to hold ships steady in the basin.

Another serious inconvenience likely to arise from this particular construction of the basin is, that whatever silt or mud is carried in by the tides must be deposited there, and cannot possibly escape. The quantity is probably not very great in the water of the Channel opposite to Cherbourg, but higher up towards Ostend it is very considerable. When we took possession of that port, it was found that, in the course of the revolutionary war, the harbour, by neglect, had been filled up with six or seven feet of mud.

Several pieces of cannon are intended to be mounted on the two piers, to protect the entrance into the basin. On one of them is likewise placed a light-house, and on the other a Semaphoric telegraph. Four slips of granite, for building large ships, were at this time constructed on the southern side of the basin, and on each of them was a ship of the line in progress; *L'Inflexible* of 118 guns, *Le Centaure* of eighty, *Le Jupiter* and *Le Généreux* of seventy-four guns each. Two other ships of the line were on the stocks without the dock-yard, nearly ready for launching, *Le Zélandais* of eighty, the first line-of-battle ship laid down at Cherbourg, and the *Duguay-Trouin* of seventy-four guns; and in the roadstead were *Le Polonais* and *Le Courageux*. In the centre of the same side of the basin, with two slips on each side of it, a noble dry-dock was cut out, or rather built, of solid granite, in which ships of the largest class might be built or repaired. Its dimensions were,

	Feet.	In.
Length.....	230	0
Width.....	74	0
Depth.....	26	6

Thus the ships built on the four slips may be launched into the basin, and at once docked out of it.

Few store-houses, or other buildings necessary for a naval establishment, are as yet erected; but there is an ample space laid out for every purpose that can be required to make Cherbourg one of the first naval arsenals in Europe; and a narrow canal, between the walls of Fort du Homet and the wall of the wet-dock, leads to a most convenient space for mast-ponds and mast-houses.

The fortifications for the protection of the anchorage in the roadstead, and the new naval arsenal, are, 1. Querque-

ville; 2. Fort du Homet; 3. Fort du Galet; 4. Fort Royal, on the isle of Peleé. Fort Royal and Fort du Homet have circular faces towards the sea, with each two tiers of guns, and turrets above them; the former mounts about eighty guns, the latter sixty-five, and Querqueville about thirty guns.

The principal channel from the road to the sea is at the western end of the breakwater, which, for large ships, is not more than half a mile in width; and this want of space will always make it difficult for ships of the line to work out: but, on the other hand, a fleet may push out to the westward in southerly winds, which lock up the English ports in the Channel.

The eastern channel is a very indifferent one, and, from the position of the isle of Peleé and the main, it is likely to become worse, from the accumulation of sand, which the French officers say is actually the case.

Such, then, were the mighty preparations of the extraordinary man who ruled France, for the destruction of the naval power of Great Britain, and with it of our national glory, pride, and prosperity, which, whether elated with success or depressed by reverses, he never ceased to devise schemes for humbling. And he had sufficient cause for his hatred, well knowing that it was England, and England's navy, that opposed the only obstacle between him and the subjugation of the world to his dominion.

To give the greater eclat to this grand undertaking, he sent the Empress Maria Louisa to be present at the opening of the basin. When the time arrived for the water to be let in, and the dam broken down, her approach was announced by flourishes of warlike music and numerous discharges of artillery. "Cries of joy," says M. Lair, "were mingled for a long time with the thunder of the batteries. Her majesty took her place in the pavilion which had been prepared for her, when the bishop of Contances, surrounded by his clergy, advancing towards her, pronounced an address suitable to the occasion. After the ceremonies and customary prayers, he turned round towards the basin, and blessed this work of man. It is delightful to see a nation consecrating by religious rites an event so memorable, and causing the divinity to intervene in all its grand undertakings." He speaks with rapture on the gratification he derived from seeing men born on the shores of the Tiber, and on the banks of the Guadalquivir, working under the direction of French engineers, at the establishment of a port in the Channel, formidable to the English navy; and he suffers no expression of regret to escape him at the idea of these poor Italian and Spanish prisoners of war being compelled to labour in chains at a work for which they were not paid, and in which they could not take the least possible interest.

The BREAKWATER IN PLYMOUTH SOUND is a work of a Break-
similar nature to that of Cherbourg, but constructed on water in
sounder principles, with less machinery and fewer people. Plymouth
Compared in extent and dimensions with that of Cher- Sound.
bourg, it is only in the ratio of about one to four.

There is no port and harbour on the south-west coast of England possessing so many advantages as Plymouth; none so well situated for assembling and equipping a fleet to watch the movements of the enemy in the harbour of Brest. Its dock-yard may be considered as the second in the kingdom in point of size, convenience, and effective strength; while the margin of it stretches along the magnificent harbour of Hamoaze,—a noble expanse of water, nearly land-locked, of a capacity sufficient for mooring safely a hundred sail of the line in excellent anchorage, and in water that carries its depth to the very quays of the yard. On the opposite or eastern side of the Sound, and at the distance of about three miles from

Break-
water.

Break-
water.

Hamoaze and the dock-yard, is another sheet of water called Catwater, not quite so deep, nor so well sheltered, as Hamoaze, but, since the progress made in the breakwater, forming a safe and commodious harbour for merchant vessels of every description. These two harbours open into Plymouth Sound and Cawsand Bay, in which ships employed in the blockade of Brest, or those refitted in Hamoaze, have been accustomed to assemble and prepare for putting to sea. But the very exposed situation of Plymouth Sound, and the heavy swell that almost constantly rolled in, especially when the wind blew fresh from the south-west to the south-east, made it so inconvenient and so unsafe an anchorage for ships of the line, that, during the late war, the fleet employed in blockading Brest had been in the practice of bearing up, when driven from its station, for the more distant anchorage of Torbay, though little better with regard to security, and worse in every other respect, than Plymouth Sound. It is, for instance, a more ineligible rendezvous for the western squadron, from the chance of the fleet being caught there by an easterly wind, and unable to get out, when it is the most favourable wind for the enemy to put to sea; from the danger to which the ships are liable when so caught at an anchorage so open and exposed; and from the inconvenience, delay, and expense of obtaining the necessary supply of stores and provisions from the other ports, there being none at Torbay.—In short, this open and exposed bay bore so bad a character among naval officers, that Lord Howe used to say it would one day be the grave of the British fleet.

It is, besides, an object of the first importance to the efficiency of every naval arsenal, to have a safe and commodious roadstead in its neighbourhood, like that of Spithead to the harbour and dock-yard of Portsmouth. Here those ships which may have gone through a course of repair or refitment, or those new from the stocks, may assemble and complete their final equipment for sea; and here, also, ships returning from sea may safely lie at anchor till the wind and tide may serve them to go into harbour. But in Plymouth Sound, ships coming out of Hamoaze, or ships going into that harbour, had no such security. By the rolling sea that set in, they were exposed to the double danger of parting their cables, or striking against the hard and rocky bottom, either of which would be almost certain destruction.

Its his-
tory.

It was most important, therefore, to render Plymouth Sound, if possible by any means, and almost at any expense, a safe roadstead for ships of war. To ascertain the practicability of this measure, Mr Rennie the civil engineer, and Mr Whidby the master-attendant of Woolwich dock-yard, were sent down by Lord Howick, now Earl Grey, at the suggestion, we believe, of Lord St Vincent, in the year 1806, with directions to examine and report, whether by any, and by what means, a sufficient shelter might be given to insure a safe anchorage for a fleet of ships of the line. The report was favourable; and several plans were offered for sheltering this sound, so as to render it capable of containing in safety above fifty sail of the line at their anchors. Nothing, however, was done or attempted, notwithstanding the increased and mighty preparations of the enemy, till Mr Yorke presided at the Board of Admiralty, when one of his first measures was to carry into execution this grand and important national object; the most important that perhaps was ever undertaken for the glory and the safety of the British navy. The delay that took place can only be explained by the frequent changes of the Board of Admiralty, which, we believe, have been fatal to many important measures for the benefit and advantage of this great bulwark of the nation.

Of the plans proposed for sheltering the Sound, one was to throw a pier from Staddon Point to the Panther Rock, a distance of 2650 yards; another, to construct a pier from Andurn Point to the Panther, a distance of 2900 yards; and a third, to carry a pier from the same Point to the Shovel Rock, being only 900 yards.

The objection urged against throwing out piers from either of these Points, and abutting against the shore, was principally grounded on the certain effect they would have of changing the current of the flux and reflux of the tide to the opposite side of the Sound, and of increasing its strength and velocity on that side, while it left all calm on the other; the inevitable consequence of which would be a deposition of mud or silt in the calm part or eddy, which, in process of time, would shallow the water, already not too deep, to such a degree as to unfit it for the reception of large ships of war.

Besides, of the three passages for large ships into Plymouth Sound from the sea, the two best are those on the two sides, while the worst was that in the middle. Either of the plans, therefore, which proposed piers to be thrown from the mainland, must have destroyed one of the best passages, and left the worst open, which was nearest to the anchorage behind the proposed pier. The middle passage might, in fact, be almost considered as shut up against very large ships by the St Carlos and the Shovel Rocks; whereas, if this middle passage should be shut up altogether, it would rather serve to deepen, by giving an increased velocity to the tide, which would scour out the bottom, than to shallow the two side passages.

On these considerations, Messrs Rennie and Whidby proposed that an insulated pier or breakwater should be thrown across the middle of the entrance into the Sound, having its eastern extremity about sixty fathoms to the eastward of St Carlos Rock, and its western end about 300 fathoms west of the Shovel, the whole length being about 1700 yards, or close upon a mile. They stated with confidence, that such a breakwater might, with every chance of success in its favour, be constructed; and that it would give shelter to ships in the Sound, without any danger of lessening the depth of water.

The middle part of the breakwater was proposed to be carried in a straight line for the length of 1000 yards; but they recommended that the length of 350 yards at each end should incline towards the straight part at an angle of 120°. See the figure, Plate CXXIX. These inclined ends would not only give shelter to a greater extent of the Sound, but would, in a greater degree, prevent the rushing in of the tide from agitating the water at the anchorage, than if the two extremities were left in the same straight line, and at right angles with the direction of the current into the Sound.

It was also proposed, in order to cover the Sound more effectually, that a pier should be thrown from Andurn Point towards the principal breakwater, of about 800 yards in length, with the same inclined point of 120° as the head of the breakwater. This pier, however, does not appear to have been thought necessary, and might have been in some respects injurious to the Sound. It might, however, have made Bouvisand Bay a good anchorage for frigates and smaller vessels, and given them the advantage of a fine stream of fresh water, which falls into that bay.

It was recommended, as the most practicable and best mode of constructing this great work, to heap together promiscuously large blocks of stone, which were to be sunk in the line of the intended breakwater, leaving them to find their own base, and take their own position; and it was conceived that stones of the weight of from one and a half to two tons each would be sufficiently large to keep

their places, without being rolled about by the tremendous swell which, in stormy weather, is thrown into Plymouth Sound; and thus avoid the inconvenience as well as loss of time and labour which the French had experienced at Cherbourg by throwing down small rubble stones. It was thought, that, in those places where the water was five fathoms or thirty feet deep, the base of the breakwater should not be less than seventy yards broad, and the summit ten yards, at the height of ten feet above the low water of an ordinary spring-tide; in other words, that the dimensions of the breakwater in those places should be forty feet high, thirty feet across the top, and 210 feet wide at the foundation.

The surrounding shores of Plymouth Sound and Catwater were next examined, with a view to determine from what quarter materials for this great undertaking could most conveniently be obtained, as to quality, cheapness, and celerity of conveyance. On the west or Cornish side of the Sound, nothing appears but hard granite; at the head of the Sound, and in Catwater, on the Devonshire side, all is marble and limestone. In Catwater alone, it was estimated, on a rough calculation, that 20,000,000 of tons might be procured in blocks fit for the work, which was about ten times the quantity that would probably be wanted. The time required for the completion of the work depended on a variety of circumstances. It is obvious that, if the two sides of the Sound had furnished proper materials for the purpose, the time would have been considerably abridged, as, in that case, when the wind was easterly vessels might deposit stones on the eastern end of the breakwater, and in westerly winds on the western extremity, and the work would thus be proceeding with an uninterrupted progress; whereas, if the stones were to be brought from one point, and that point was on the shore of Catwater, a strong southerly and south-westerly wind, those most prevalent in this country in the winter months, would generally impede and frequently render it impossible for vessels to go off with their cargoes.

Catwater, however, having many advantages, especially for the convenience of loading the vessels, and the facility of procuring blocks of any size from the quarries, was considered, on the whole, as entitled to the preference over any other place. Besides, the quarries here being in the neighbourhood of villages, lodgings and conveniences would be afforded for the workmen; and, on the whole, it was calculated that the work might be completed from hence at a cheaper rate, and perhaps in less time, than from situations much nearer to it, but much more exposed to the wind and waves.

An estimate of the expense could not be made with any degree of accuracy, as no correct section of the bottom had been taken. Supposing, however, the great breakwater to be 1700 yards in length, thirty feet in width at the top when carried ten feet above low water of spring-tides, with a slope on the southern or sea side of three feet horizontal to one foot perpendicular, and on the Sound or land side of one foot and a half horizontal to one perpendicular, it was calculated that the whole mass of stone required would be about 2,000,000 of tons. If then a hundred sail of vessels of fifty tons burden each were employed in carrying stone, and each vessel carried only 100 tons a week, the quantity deposited in one week would amount to 10,000 tons, or 500,000 tons a year, and at this rate the breakwater would be completed in four years; but making allowance for time lost in preparations, contingent delays, unfavourable weather, and deductions in the quantity of stone for the shallow parts over which the line of the breakwater was carried, the completion of the work might safely be calculated within the period of six years.

Nor would the building of the pier from Andurn Point, if so determined, increase the time of completion. If carried from the shelving rocks within the Point, leaving a passage between them, the pier would require about 360,000 tons of stone, which, by employing about thirty vessels, might be deposited in three years.

It was recommended by the gentlemen above mentioned, that the great breakwater should be begun on the Shovel and extended on both sides of it, as, by so doing, the effect produced on the Sound would be observed as the work proceeded; and that buoys should be placed along the line, so that the whole of the vessels employed might, if necessary, deposit their cargoes at the same time without interrupting each other.

The rough estimate for completing this great national work, made on the grounds above stated, was as follows:

Estimate of the Probable Expense of a Breakwater and Pier for the Sheltering of Plymouth Sound and Bournisand Bay.

2,000,000 tons of limestone, in blocks from 1½ to 2 tons weight each, for the great breakwater, at 7s. 6d. per ton.....	L.750,000	0	0
360,000 tons in the pier proposed to be built from Andurn Point, at 7s....	126,000	0	0
Contingencies, say at 20 per cent. on the whole.....	175,200	0	0
Total for the great breakwater.....	L.1,051,200	0	0

Estimate of the Probable Expense of a Cut-Stone Pier and Two Light-houses to be built on the top of the Great Breakwater.

42,000 cubic yards of masonry, in the out and inside walls of the pier, at 27s.....	L.44,700	0	0
62,000 cubic yards of rubble filling between the out and inside walls, at 6s.	18,600	0	0
Paving the top of the pier with large blocks of stone, 8500 square yards...	22,950	0	0
Two light-houses, with reflectors and and argand lamps.....	5,000	0	0
Contingencies 20 per cent.....	28,650	0	0
	L.119,900	0	0
Breakwater,	1,051,200	0	0

Total estimate of completing the works..... L.1,171,100 0 0

It was not until the opinions of the best engineers, men of science, and naval officers eminent in their profession, had been collected, compared, and seriously considered, that Mr Yorke determined to carry into execution this great undertaking. The principal objection started against it was, that it might cause the anchorage in the Sound to be destroyed in the course of time by the deposition of mud and silt along the whole eddy within it. But there does not appear to be any solid ground for this objection. The water brought by the tides from the sea is at all times perfectly clear and transparent, and that which proceeds from Hamoaze, and is supplied by the Tamar and the Tavy, is almost wholly free from any alluvial matter, these rivers holding their course through a fine granitic soil. The fact is sufficiently proved by the circumstance of no deposition taking place in the recesses of Hamoaze along the dock-yard wall leading into the docks, nor in the numerous eddies that are caused by the projecting jetties and salient angles of that wall. Another objection started against the undertaking was, that by the diminish-

Break-water.

Break-water.

ed quantity of water thrown by the tide into Hamoaze and Catwater, the Sound would gradually fill up, and these harbours be destroyed. But no perceptible alteration has as yet taken place in the height of the water in Hamoaze, or in the strength or set of the tides.

Commencement of the work.

A rock of limestone, or rather gray marble, situated at Oreston, on the eastern shore of Catwater, consisting of a surface of twenty-five acres, was purchased from the Duke of Bedford for the sum of L.10,000. Quays for shipping the stone were erected in front of it; iron railways leading from the quarries to the quays were laid down; ships were hired by contract to carry off the stone, and others built at the dock-yard. Mr Whidby was appointed to superintend the work. The quarries were opened on the 7th August 1812; the first stone was deposited on the 12th of the same month; and, on the 31st March 1813, the break-water made its first appearance above the surface of the Sound at low water of the spring-tide. The system of quarrying the stone was conducted with admirable skill, and stones of the proper size were obtained with less waste of small rubble than might have been expected. In working these quarries an extraordinary phenomenon was discovered in the very body of the great mass of this old marble rock. At the depth of sixty-five feet from the summit of the rock, and twenty-five from the margin of the sea, a cavity, or rather a nodule of clay, was discovered, of twenty-five feet long and twelve square, or thereabouts, in the midst of which were found several bones of the rhinoceros, in a more perfect state, and containing less animal matter in them, than any fossil bones that have yet been dug out of rock or earth.

Machinery employed.

The vessels employed for carrying off the large blocks of stone were of a peculiar construction, adapted to convey with ease masses of marble weighing from three to five tons each. These great blocks of marble were placed on trucks at the quarries, and run down from thence on iron railways to the quays, against which the vessels lay with their sterns. The two stern ports were made sufficiently large to receive the trucks with the stones upon them. Each truck was passed separately through the port-hole on an inclined plane, and run to the fore-part of the vessel in the hold on an iron railway. The two sides of the hold of the vessel were calculated each to contain eight of these loaded trucks, which, at five tons on each truck, gave eighty tons of stone for one cargo. The stones thus placed on the trucks remained till the vessel arrived at the point in the line of the breakwater where they were to be deposited. By means of a crane on the deck of the vessel, the two trucks nearest to the two stern ports were then drawn up the inclined plane, and run upon a frame on movable hinges, called the *typing-frame*; by the falling of this frame in the manner of a trap-door the stone or stones were discharged from the trucks on the slope of the break-water; but the typing-frame remained, by means of a catch, in the position in which it was left at the moment of discharging the stones, until the empty truck was pulled up by the crane to the after-part of the deck, from whence it was run forward to make room for the second pair of loaded trucks in the hold. The catch being now disengaged, the typing-frame returned to its former position, ready to receive the next pair of loaded trucks, and so on till the whole sixteen were discharged; and the light trucks ran upon the deck of the vessel, ready to be run out at the quay, and from thence to the quarries, to take in fresh loads of stone. In this manner a cargo of eighty tons was discharged in the space of forty or fifty minutes. The vessels were placed in the proper places for depositing the stones by means of buoys, and the exact line of the break-water was preserved by observing lights or staves placed at a distance on the shore.

The following description, referring to Plate CXXVIII., will convey an accurate idea of these excellent vessels for the purpose for which they were constructed.

Fig. 1 shows the stern of the vessel in the act of depositing the stones. The runner R being hooked to the fore-part of the truck, raises it up, and by that means tips the stone overboard. When the stone is in the act of being drawn up out of the hold on the inclined plane B (fig. 3), the runner is hooked to the fore-part of the truck, and lashed down to the after-end over the stone, which prevents the latter from sliding off the truck in its progress up the inclined plane. The empty trucks are for the most part lodged on the fore-part of the deck, and some placed on an edge against the side of the vessel.

Fig. 2 shows the stern of the vessel when loaded, with the ports up or closed.

Fig. 3 is a longitudinal or sheer-section of the vessel when loaded, with the trucks on one side of the hold and deck, showing the number which the vessel usually stows on each side. The stones being frequently longer than the trucks, the number carried in the hold must be proportioned accordingly. In bad weather it is unsafe to send many trucks on deck; and, in general, not more than four are sent into the Sound in that way at one time; the amount of the cargoes, therefore, vary, according to circumstances, from forty to sixty-five tons; the largest stone hitherto deposited being about eight tons.

The after-part of the deck under the tiller is divided into two parts length ways, and made to move up and down; the fore-parts are secured to a beam by hinges. This movable deck, when raised as at X, allows the stones to come out of the hold, and when down, as at Y, serves to convey the empty truck from the port to the deck, in order to make room for another stone.

D is a common windlass for heaving the trucks out of the hold up the inclined plane B.

C, the hinges of the typing-frame.

Ten vessels of this construction, for carrying large masses of stone, built in the King's Yards, and forty-three hired by contract, averaging about fifty tons each, were employed in conveying stones from the quarries. The contractors' vessels were not of the same construction as those in the immediate employ of government; they carried stones of less weight, which were hoisted out of the hold by a chain and windlass, and thrown overboard. A load of fifty tons was discharged from one of these vessels in about three hours. By all these vessels the quantity of stone deposited in 1812 was 16,045 tons; in 1813, 71,198 tons; in 1814, 239,480 tons; in 1815, 264,207 tons; and in 1816, up to 12th August, 206,033 tons, at which time the total quantity of stone sunk amounted to 896,963 tons; and at the conclusion of the year to upwards of 1,000,000 tons.

Of this quantity the proportions of the different sizes of the blocks deposited were nearly as follow:

	Tons.
Of one ton each stone, and under.....	423,904
Of one to three tons each.....	309,706
Of three to five tons each.....	150,593
Of five tons and upwards	12,760

The original contract price for quarrying the stone was 2s. 9d. per ton, and the original contract price for conveying it to the breakwater 2s. 10d. per ton; but the former was reduced to 2s. 5d., and the latter to 1s. 10d. per ton. The cost of each ton of stone sunk in the breakwater, including the building of quays, purchase of land, salaries, and every other expense, according to the nearest calculation that can be made, amounted to about 8s. 1½d., which, upon the whole quantity deposited, gave a total sum expended up to 12th August 1816 equal to L.364,000. And as the work might be considered as more than half com-

pleted, it would have been finished considerably within the original estimate, and, if parliament had thought fit to grant the money, within the time.

The greatest quantity of stone sunk in any one week was 15,379 tons; and the part of the breakwater, at the date just mentioned, above the level of low-water spring-tides, was in length 1100 yards. The length completely finished to the height of three feet above the level of the highest spring-tides, and thirty feet wide at top, was at the same time 360 feet. The large stones of the upper part of the breakwater were deposited to any nicety by means of a vessel constructed for the purpose, having the same sheer or slope at the bow with the side of the work, so that by a projecting beam or mast the largest stones could be taken out of the vessel, and placed on the opposite side, or middle, or any other part of the breakwater.

The small establishment, and the quick manner in which this great work was carried on, form a curious contrast with the multitudes employed on the breakwater of Cherbourg, the time occupied by that undertaking, and the parade and ostentation with which it was conducted.

The whole establishment for carrying on the Plymouth breakwater was as follows:

	Persons.
A superintendent, with proper officers and clerks, to keep and control the accounts.....	10
Warrant officers and masters of the ten stone vessels in the immediate employ of the public.....	21
Seamen and boys to navigate these vessels.....	90
Seamen employed in the superintendents' vessels, the light vessel, boats' crews, &c.....	45
Masons, blacksmiths, carpenters, sail-makers, and labourers, employed at Oreston.....	39
In the immediate pay of government.....	205
Seamen employed in the contractors' vessels.....	170
Quarrymen, labourers, &c. employed at Oreston by the contractors.....	300
Total establishment.....	675

The result of this great work has completely answered the expectation of its warmest advocates. The good effects of it were, indeed, very sensibly felt at the end of the second year, when about 800 yards of the central part, where the water was shallowest, were visible at low-water spring-tides. The swell was then so much broken down and destroyed at the head of the Sound, that the fishermen were no longer able as heretofore to judge of the weather outside the Sound; and ships of all sizes, and among others a French three-decker, ran in with confidence, and anchored behind the breakwater. Since that time near two hundred sail of vessels of all descriptions, driven in by tempestuous weather, have at one time found safe shelter within this insulated mole, where a fleet of twenty-five to thirty sail of the line may at all times find a secure and convenient anchorage, with the additional advantage of having a stream of excellent water from a reservoir constructed above Bouvisand Bay, capable of containing from ten to twelve thousand tons, or a quantity sufficient to water fifty sail of the line. This water is brought down in iron pipes to Staddon Point, opposite to the anchorage, where a jetty has been completed, from which the water descends through the pipes into the ships' boats. The whole expense of this most useful appendage to the breakwater is calculated at about L.16,000.

During the winter of 1816-17 the gales of wind were more frequent and tremendous than had been known for many years; and, on the night of the 19th January, such a hurricane came on as had not been remembered by the oldest inhabitant. The tide rose six feet higher than the

usual height of spring-tides. The *Jasper* sloop of war, and the *Telegraph* schooner, being anchored without the cover of the breakwater, were driven to the head of the Sound, and both lost; but a collier deeply laden, and under its cover, rode out the gale. No damage was sustained by any of the shipping in Catwater; but it was the general opinion, from former experience, that, if no breakwater had existed, the whole of the ships therein must have been wrecked, and the storehouses and magazines on the victualling premises, and most of the buildings on the margin of the sea, must have been entirely swept away. Till this tremendous gale the breakwater had not sustained the slightest damage from the heavy seas that, through the winter, had broken against it with unusual violence, not a single stone having moved from the place in which it was originally deposited; but after the hurricane, above-mentioned, and the high tide which accompanied it, it was found that the upper stratum of the finished part, extending about 200 yards, and thirty yards in width, had been displaced, and the whole of the huge stones, from two to five tons in weight each, had been carried over and deposited on the northern slope of the breakwater. In no other part could it be discovered that a single stone had been displaced. Since that time a considerable portion of the sea-front has been eased with masonry of immense masses of stone, but smoothly and beautifully laid; and the better to protect this, the foot of the slope is being extended seaward, in order to protect the foot of the masonry, by throwing in a great quantity of large and rubble stones, which will complete the work within the original estimate, and, it is calculated, some time in the year 1833.

The want of a harbour, or any place of safety to which ships can resort in bad weather, or in distress, between the ports of Plymouth and Portsmouth, led to the suggestion of Portland Roads being converted into a secure harbour by means of a breakwater. It was estimated that the construction of such a stone dike, extending from the north-east part of Portland Island, about two miles and a quarter in length, covering an anchorage of about four square miles, and completely sheltering the pier, harbour, and bathing place of Weymouth, would require about four millions of tons of stone, five years to complete it, and an expense of about six hundred thousand pounds Sterling. The capstone alone, which covers the Portland stone, and which, being unmarketable, is not only useless, but a great incumbrance, would be sufficient to complete this great undertaking. Such a secure anchorage in this situation, in which the largest fleets, either naval or mercantile, might ride at anchor in all winds and the most stormy weather in perfect security, is not unworthy the consideration of the public; and, perhaps, in the present increased state of our population, and the difficulty of finding employment for the labouring poor, there can be no truer policy than that of carrying on great national works of public utility, were it only for the sake of encouraging industry, instead of expending an equal, or probably a far greater sum, for the support of idleness and the encouragement of vice in those parochial buildings too frequently miscalled work-houses.

(M.)

BREAM. See *ICHTHYOLOGY*, *Index*.

BREAST, in *Anatomy*, denotes the fore-parts of the thorax. Smiting the breast is one of the expressions of penitence. In the Romish church the priest beats his breast in rehearsing the general confession at the beginning of the mass.

BREAST-HOOKS, in *Ship-Building*, are thick pieces of timber incurvated into the form of knees, and used to strengthen the fore-part of the ship, where they are placed at different heights directly across the stem, so as to unite it with the bows on each side. The breast-hooks are

strongly connected to the stem and hawse-pieces by tree-nails, and by bolts driven from without through the planks and hawse-pieces, and the whole thickness of the breast-hooks, upon the inside of which these bolts are forelocked or clinched upon rings. They are usually about one third thicker than, and twice as long as, the knees of the decks they support.

BREAST-Plate, in *Antiquity*, a piece of armour worn to defend the breast, and believed to have been originally formed of hides or hemp, twisted into small cords, but latterly made of brass, iron, or other metals, which are sometimes hardened so as to be proof against the greatest force.

BREAST-Plate, in *Jewish Antiquity*, one part of the vestments anciently worn by the high-priests. It was a folded piece of the same rich embroidered stuff of which the ephod was made; and it was set with twelve precious stones, on each of which was engraven the name of one of the tribes. They were set in four rows, three in every row, and were divided from one another by little golden squares or partitions, in which they were set. The names of these stones, and those of the tribes engraven on them, as also of their disposition on the breast-plate, were as follow:

<i>Sardine</i> REUBEN.	<i>Emerald</i> JUDAH.	<i>Ligare</i> GAD.	<i>Beryl</i> ZEBULON.
<i>Topaz</i> SIMEON.	<i>Sapphire</i> DAN.	<i>Agate</i> ASHER.	<i>Onyx</i> JOSEPH.
<i>Carbuncle</i> LEVI.	<i>Diamond</i> NAPHTHALI.	<i>Amethyst</i> ISSACHAR.	<i>Jasper</i> BENJAMIN.

This breast-plate was fastened at the four corners, those above to each shoulder by a golden hook or ring at the end of a wreathed chain; and those below to the girdle of the ephod, by two strings or ribbons, which had likewise two rings and hooks. This ornament was never to be severed from the priestly garment; and it was called the Memorial, to remind the high-priest how dear those tribes ought to be to him, whose names he wore on his breast. It is also called the Breast-plate of Judgment, because it had the divine oracle of Urim and Thummim annexed to it.

BRECHIN, a town of Scotland, in the county of Forfar and parish of Brechin, is situated on the face of a hill about the centre of the parish, on the left bank of the River South Esk, which is crossed below the town by a stone bridge of two arches. Brechin consists of one main street running north and south, with several smaller streets. On the south, the town is continued by two suburbs named the Upper and Nether Tenements, which hold in feu of the families of South Esk and Panmure.

This town is said to have been the capital of Pictavia, and the royal seat of the Pictish kings; and the hill of Caterthun, about four miles north of the town, surrounded with an immense coronal of loose stones, is supposed to have been a fortification belonging to that ancient nation. In the earliest record extant, the name of the town is spelt as at present; but as in the days of St Columba there was a noted Druid of the name of "Broichan," probably the town may have derived its appellation from some such source. The Culdees are reported to have had a convent here; and their abbot Leod was witness to the grant made by King David to his new abbey of Dunfermline. In after-times the Culdees gave way to the Mathurines or Red Friars, the ruins of whose house, according to Maitland, are still to be seen in the College or Chandry Wynd.

Brechin was founded into a bishopric by David I. about

1150. At the Reformation its revenues amounted in Brechin money and kind to £700 per annum; but after that event they were miserably reduced by various grants, and mainly by the alienation of lands and tithes, by Alexander Campbell, the first Protestant bishop, to his chieftain the Earl of Argyll. In 1572 James VI. with consent of John Earl of Morton, Regent, founded an hospital in the burgh. "Mr George Buchanan, pensioner of Crossragwell," is one of the witnesses to the grant, which was ratified by his majesty in 1587, when he attained majority. The magistrates and council are patrons of this charity, from which they give a small weekly allowance to the poor, no hospital apparently having ever been erected. William de Brechin founded a chapel in 1256, called Maison de Dieu. Albinus, bishop of Brechin in the reign of Alexander II. was witness to the grant. Parts of the walls of the chapel still remain in the Maison Dieu Vennel, a little west of the High Street, and prove that the chapel had originally been an elegant little building. The house itself, and the property about it, with the superiority of some other lands, are generally gifted by the crown to the rector of the grammar-school during his incumbency, who hence takes the title of preceptor of Maison-dieu. The cathedral, which is now used as the parish church, was originally a handsome Gothic building; but its appearance has been much injured by modern "improvements." The steeple attached is a noble-looking square tower, with an octagon spire, rising to the height of 128 feet. Close to the church stands the round tower, one of those singular structures which are generally supposed to have been places of look-out belonging to the Picts, although their real use has long baffled the research of antiquaries. These towers are peculiar to North Britain and Ireland; in the latter they are frequent, in the former only two at this time exist, one at Brechin and another at Abernethy. There is no stair in the Brechin tower, and the only access to the top is by means of six ladders placed on wooden semicircular floors, which rest on circular projections within the tower. The height from the ground to the roof is eighty-five feet, the inner diameter within a few feet of the bottom is eight feet, and the thickness of the wall at that part four feet two inches, so that the whole diameter is nearly sixteen feet; the circumference is very near forty-eight feet; the inner diameter at top is six feet seven inches, the thickness of the wall two feet ten inches, and the circumference thirty-eight feet eight inches. These proportions give the building an inexpressible elegance. The top is roofed with an octagonal spire eighteen feet high, which makes the whole height of the building 103 feet. Certain it is, that during strong winds this tower has often been observed to vibrate. A stone built into the wall of the church-yard, evidently modernized, but most probably copied from an older stone, records, in not inelegant Latin, that during 1647 six hundred persons died of the plague in Brechin in the course of four months.

Within the burgh there is a house said to have been a *Hospitium* of the knights templars, now appropriately used as an inn. These knights seem to have had some lands in the neighbourhood, as there is a piece of ground close by Brechin bearing the title of Temple Hill of Bothers. A little to the north of this last-mentioned place is Huntly Hill, remarkable for the battle fought there between the Earls of Huntly and Crawford, in consequence of the rebellion raised in 1452, on account of the murder of the Earl of Douglas in Stirling Castle. The victory fell to the royalists under Huntly, who has hence given his name to the ground.

Brechin Castle, the seat of Lord Panmure, stands on the brink of a perpendicular rock overhanging the South Esk, a little to the south of the town. This castle was

con. besieged by the English under Edward I. in 1303, and was for twenty days gallantly defended by Sir Thomas Maule, ancestor of the family of Panmure, who was slain by a stone thrown from an engine placed on the opposite rising ground, when the castle was instantly surrendered. The south front of the castle above the river presents a romantic mixed mass of buildings, covered with ivy, and showing some remains of the original structure. The west front forms a regular building, in the style of the seventeenth century.

Brechin was burnt by the Danes in 1012, and by the Marquis of Montrose in 1645. At present it has a neat appearance, the excellent free-stone quarries in the vicinity giving every opportunity for substantial erections. The chief manufactures of this place consist of various branches of the linen trade. There is also an extensive distillery in the town, and a smaller one in the immediate vicinity; and at the mills of Brechin a good deal of wheat is ground for distant markets. Brechin has a market every Tuesday, which is well frequented by dealers in grain. About a mile from the town, on the Trinity Muir, four annual fairs are held, the principal of which takes place in June. The town is governed by a provost, two bailies, a dean of guild, seven merchant and two trades' counsellors. This burgh is the seat of a presbytery, and, besides the Presbyterian church, it contains a neat Episcopal chapel, two meeting-houses belonging to the United Associate Synod, one belonging to the Original Seceders, and a Relief chapel. There is an endowed grammar-school under a rector, and a parochial school under two teachers besides assistants, with several private schools, in the town.

Maitland, the laborious historian of Edinburgh and London, and Dr John Gillies, the historian of Greece, were natives of this place. James Tytler, an eccentric and unfortunate personage, one of the contributors to the early editions of the *Encyclopædia Britannica*, was born in the immediate neighbourhood. The population of the town and Tenements in 1831 was 5060. Brechin is eight miles from Montrose, thirteen from the county town of Forfar, forty-two from Aberdeen, and the same distance from Perth. Long. 2. 18. W. Lat. 56. 40. N.

BRECON, or BRECKNOCK, a market and borough town, the capital of the county of the same name, in South Wales, 168 miles from London, is situated at the confluence of the rivers Hondey and Uske. Its ancient castle, an object of great curiosity to the antiquarian, is said to have been built in the reign of William Rufus. There are several traces of Roman encampments in the vicinity. Its present state is not flourishing, as the manufactures of cloth and of stockings which once existed have been removed to more favourable spots. It contains three churches, and is governed by a corporation, which, with the freemen, returns one member to parliament under the influence of Sir Charles Morgan. There are markets on each Wednesday and Saturday. The inhabitants amounted in 1801 to 2576, in 1811 to 3196, in 1821 to 4193, and in 1831 to 5026.

BRECONSHIRE, or BRECKNOCKSHIRE, in South Wales, is divided from Radnorshire by the river Wye; its other boundaries are artificial. Its length is twenty-nine miles, the breadth of its southern basis thirty-four, and its circumference rather more than a hundred. It contains nearly 500,000 acres of land, not one half of which is either in a state of cultivation or adapted to it. Its form is irregularly triangular, narrowing towards the northern extremity. It is divided into six hundreds; and contains the county town, Brecon, and three market-towns besides, Crickhowel, Biulth, and Hay. There are in it a hundred and eleven parishes, and places paying parochial rates, according to the last returns to parliament respecting these rates.

Breconshire is one of the most mountainous counties in Wales; and the Van, or Brecknock Beacon, is one of the loftiest mountains. Ridges of hills, which form the separation of this from most of the adjacent counties, shelter it in such a manner as to render it temperate. It appears, from observations made in the year 1802, with a rain gauge, that $26\frac{1}{4}$ inches of rain fell at Brecon. There is a considerable variation not only in the surface of the country, but also in the nature of the strata. In the hundred of Biulth the soil is remarkably argillaceous, and the water does not sink sufficiently deep; in the Vale of Uske, on the contrary, it is too porous to retain the necessary moisture. In general, the soil of the vales consists of a light loam, lying on a deep bed of gravel; the soil of the hills is for the most part argillaceous. The principal river, next to the boundary one of the Wye, is the Uske, which, taking its rise from the black mountain, in the western side of the county, on the border of Caermarthenshire, flows across it through a fine valley to the south eastern angle, passing the town of Brecon. A little to the east of the town of Brecon is a considerable lake, well stored with fish, out of which a rivulet runs to the Wye. The Brecon Canal unites with the Monmouth Canal eight miles and a half from Newport and one mile from Pontypool; it crosses the river Avon, is carried through a tunnel 220 yards in length, passes the town of Abergavenny towards the river Uske, and proceeds parallel with that river to Brecon, being thirty-three miles in length, with sixty-eight feet rise to Brecon. By the fall of this canal from Brecon to the Bristol channel, it appears that Brecon is 411 feet eight inches above the level of the sea.

The agriculture of this county is superior to that of most of the other counties of Wales, and appears to have begun to improve about the middle of the last century, as the Breconshire Agricultural Society was instituted in 1775, being one of the first associations of the kind in the island. The mode of culture in the good soils is conducted in the best manner; but where the land is naturally poor, the tillage is very bad. In the Vale of Uske, the Norfolk rotation is followed with skill and success; and tolerably abundant crops of barley, clover, wheat, and turnips are obtained. The Highland farmers, in general, are too poor to attempt any material improvements. In the vales the farms seldom exceed 150 or 200 acres; the rents are high—in the neighbourhood of Glazbury and Hay nearly forty shillings the cyfair, which is about one third less than the statute acre; the poorest grounds do not let for more than four or five shillings the cyfair.

The principal exports of the county are wool, butter, and cheese. Of the first, a considerable quantity is spun and knit into stockings in the hundred of Biulth, and in different parts of the Highlands; the stockings are bought by hosiers and carried to the English market. Some sheep, a few horned cattle, and a considerable number of swine, are frequently driven to Worcester, London, Bristol, &c. The cattle and horses are small, but the former have been much improved by intermixing the Glamorganshire and Herefordshire breeds; and the latter by the introduction of the Suffolk Punch sort. A considerable number of otters frequent the rivers, the furs of which form another branch of the exports of this county.

The manufactures which formerly existed in this county consisted of flannel, linsey-woolsey, and a coarse kind of cloth worn by the labourers; but of late these have become nearly extinct. The mines of iron and coal have, however, been very much extended; and many forges and founderies have been constructed, which give employment to a considerable part of the population in that part of the county which is contiguous to Monmouthshire.

The county confers the title of Earl on the Marquis of

Breda
||
Greenberg.

Camden. It returns to parliament one member for the county and one for the town of Brecon. It is comprehended in the bishopric of Landaff, and, by a late law, in the Oxford new circuit.

At the three decennial enumerations, the population of the county, and the number of houses, appeared thus :

Year.	Males.	Females.	Total.	Houses.
1801.....	15,393.....	16,240.....	31,633.....	6,315
1811.....	18,507.....	19,228.....	37,735.....	7,555
1821.....	21,853.....	21,760.....	43,613.....	8,425
1831.....	23,896.....	23,867.....	47,763	

Of the families in the last of these years, 4049 were employed in agriculture, 3703 in manufactures, trade, or handicrafts, and 1280 were included in neither of these classes.

BREDA, a city, the chief of a circle of the same name, in the province of South Brabant, in the Netherlands. It is well built and strongly fortified, and the country around can be flooded for defence in case of necessity. It is connected with the sea by a navigable canal, which communicates with the mouth of the Maas. It is celebrated for the peace concluded here in 1667. It contains about 1000 houses and 10,500 inhabitants. Long 4. 40. 19. E. Lat. 51. 25. 29. N.

BREDA, *John Van*, an historical and landscape painter, was born at Antwerp in 1683. He was the son of Alexander Van Breda, an artist much esteemed for landscapes, views of particular scenes in Italy, fairs, and markets, with a variety of animals and figures.

BREDSTEDT, a town, the capital of a bailiwick, containing one town and nine parishes, in the duchy of Sleswick and kingdom of Denmark. It stands on the sea-shore, and contains 309 houses, with 1590 inhabitants. Long. 8. 53. E. Lat. 54. 38. N.

BREECHES, a garment worn by males, reaching from the girdle to the knees, and serving to cover the hips, thighs, and knees. The ancient Romans had nothing in their dress answering to our breeches and stockings; instead of which, under their lower tunics and waistcoats, they sometimes bound their thighs and legs round with silken scarfs or fasciæ, which were called *tibialia* and *femoralia*. Breeches appear to be a habit peculiar to the barbarous nations, especially those inhabiting the colder countries of the north; and hence Tacitus calls them *barbarum tegmen*. We find mention made of them among the ancient Getæ, Sarmatæ, Gauls, Germans, and Britons; they also obtained amongst the Medes and Persians, who were of Scythian origin; and they afterwards got footing in Italy, some say as early as the time of Augustus, but without much foundation, since the breeches of that emperor, mentioned by Suetonius, were apparently only swaths tied round his thighs. But however this be, breeches were at last received into Italy, and became so much in fashion, that it was judged necessary, under Arcadius and Honorius, to restrain them by law, and expel the *bracarii* or breeches-makers out of the city, it being thought unworthy of a nation which commanded the world to wear the apparel of barbarians.

BREENBERG, BARTHOLOMEW, a painter, was born in 1620. He is best known by the name of Bartolomeo, an appellation bestowed upon him, for the sake of distinction, by the society of Flemish painters at Rome called Bentvogels. He was born at Utrecht, but in the early part of his life went to Rome. His studies in the art of painting were attended with success, and his pictures were held in much estimation. He particularly excelled in landscapes, which he enriched with historical subjects. The figures and animals which he introduced were very spirited, and drawn in a masterly manner; especially when they were not larger than the size in which he usually painted them.

He died in 1660, at the age of forty. He also etched from his own designs a set of twenty-four Views and Landscapes, ornamented with Ruins.

BREEZE, a shifting wind that blows from sea or land during certain hours in the day or night. It is common in Africa and some parts of the East and West Indies. Breezes differ from *etesia* or trade-winds, inasmuch as the former are diurnal, or have their periods each day, whilst the latter are annual, and blow at a distance from land. The sea-breezes prevail by day and the land-breezes by night, so that they remain as constant as the seasons of the year, or the course of the sun, on which they seem to depend, although they come on sooner or later, stronger or weaker, in some places than in others, and vary according to latitude and other circumstances.

BREGENTZ, the capital of the circle of Voralberg, in the Austrian province of Tyrol, stands on a hill at the south-east end of the lake of Constance. It has three churches, a Dominican monastery, and about 2200 inhabitants, occupied in silk and cotton manufactures, and in making various iron wares.

BREHAR, one of the Scilly Islands, lying almost directly west of the Land's End in Cornwall, about the distance of thirty miles. It is situated between the isles of Micarol, Guel, Trescaw, and Samson, and is the roughest and most mountainous of them all. Not long ago there were only two families on it, but now the number has considerably increased. There are a few miserable houses, called the town of Brehar; and also several barrows edged with stone, in which considerable persons were burned in ancient times; besides many monuments of the Druids. Some are of opinion that this, with the rest, originally made but one island; which is probably the reason why so many antiquities are now found in most of them.

BREHONS, the provincial judges among the ancient Irish, by whom justice was administered and controversies decided. These sages were a distinct tribe or family, to whom competent lands were allowed in inheritance. In criminal cases the brehon had the eleventh part of all the fines; which could not but be considerable at a time when murders, rapes, robberies, and the like offences, were only subject to pecuniary commutations.

BREION-Laws, or *Leges Brehonicae*, denote the general maxims or rules observed by the Brehons, and which had the force of laws throughout all the provinces of Ireland.

BREISACH, a bailiwick in the circle of Treisam, of the duchy of Baden, on the Rhine, containing two cities, twelve villages, and six hamlets, with 13,215 inhabitants. The chief city, of the same name, celebrated for its former strong castle, stands on the Rhine, and has a population of 2711 persons. Long. 7. 28. 30. E. Lat. 48. 1. 48. N.

BREMEN STATE. See GERMANY.

BREMEN, a province of the kingdom of Hanover, which, together with Verden, was secularized at the treaty of Westphalia in favour of Sweden. In a war between Denmark and Sweden in 1712, it was conquered by the former kingdom, who sold it to the house of Hanover, to whom it was, after much negotiation, confirmed by imperial edict in 1732. It is bounded on the north-east by the Elbe, on the north by the German Ocean, on the east by Lüneburg, on the south by the province of Hoya and a part of Brunswick, on the south-west by the republic of Bremen, and on the west by Oldenburg. It extends over about 2696 square miles, or 1,665,440 acres. On the borders of the sea and of the Elbe there is a narrow strip of good marsh and corn land, though the greater part of the interior of the province is a most sterile sandy district; but by the attention which the Duke of Cambridge has devoted to the roads, the interior has been vastly improved within the last twelve years, and the cultivation much extended.

Breeze
||
Bremen.

Brenage The population has also rapidly increased in the same period. In 1816 it amounted to 207,212, and at the end of 1826 to 230,235 individuals. It contains four cities, twenty-three market-towns, 125 parishes, and 924 hamlets. The inhabitants are Lutherans, with the exception of seven churches, which are served by pastors of the reformed confession.

BRENNAGE, **BRENNAGIUM**, in the writers of the middle ages, a kind of tribute paid in lieu of bran, or bran itself, which the tenants were obliged to furnish for the support of the lord's hounds. The word is also written *brénage*, *brénagium*, and *brénaige*, *brénagium*, *brénaticum*, and *brénaticum*.

BRENNUS, a celebrated captain among the Gauls, who, about 388 years before the Christian era, entered Italy with a powerful army, made great conquests there, defeated the Romans, and sacked Rome. The Capitol alone was defended; and Camillus coming to its relief, drove the Gauls not only out of Rome, but also out of Italy.

BRENTFORD, a town, being a hamlet in part of the parish of Hamwell and hundred of Ossulton, in the county of Middlesex, seven miles from London, on the banks of the Thames. It consists of a single long street, and comprehends two parishes, with their respective churches. It is remarkable as the place where elections for the county are held, and as the greatest thoroughfare for carriages of any in England, though the street is narrow, and impediments often present themselves to obstruct the road. Near it is the magnificent palace of the Duke of Northumberland, Sion-House; and on the opposite bank of the Thames the royal palace of Kew, with its magnificent botanical garden. There is a well-supplied market on the Tuesdays.

BREREWOOD, **EDWARD**, an English mathematician and antiquary, was the son of Robert Brerewood, a tradesman, who was thrice mayor of Chester, and born in that city in the year 1565. He received the rudiments of his education at the free school in Chester; and was afterwards admitted, in 1581, of Brazen-nose College in Oxford. In the year 1596 he became the first professor of astronomy in Gresham College, London; and there led the same private and retired course of life as he had before done in Oxford. He died of a fever upon the 4th of November 1613. He was a great searcher into antiquity and curious knowledge, but never published any thing during his lifetime. After his death came out the following works: —1. *De Ponderibus et Pretiis veterum Nummorum eorumque cum recentioribus Collatione*, 1664, 4to; 2. *Inquiries touching the Diversities of Languages and Religion through the chief parts of the world*, London, 1614, 4to; 3. *Elementa Logice in gratiam studiosæ juventutis in Academia Oxon.* London, 1614, 8vo, and Oxford, 1628, 8vo; 4. *Tractatus quidam Logici de prædicabilibus et prædicamentis*, 1628, 8vo; 5. *Two Treatises on the Sabbath*, 1630 and 1632; 6. *Tractatus duo, quorum primus est de Meteoris, secundus de Oculo*, 1631; 7. *Commentarii in Ethicam Aristotelis*, Oxford, 1640, 4to; and, 8. *The Patriarchal Government of the Ancient Church*, Oxford, 1641, 4to.

BRESCIA, one of the delegations into which the Austrian kingdom of Venetian Lombardy is divided. It is bounded on the north-west by Bergamo, on the north-east by the Tyrol, on the east by the Lake of Guarda, on the south-east by Mantua, on the south by Cremona, and on the south-west by Lodi. Its extent is 1115 square miles, or 713,600 acres. It is divided into twelve districts, and these into 238 communes or parishes; and it comprehends one city, thirty-two market-towns, and 202 villages, containing 50,840 houses. The inhabitants, in 1816, amounted to 311,596, of whom 157,572 were males, and 154,024, females; but since that period they have rapidly increased.

The northern part, or one third of the delegation, consists of a chain of mountains, which belong to the Rhetian Alps; the remainder is part of the great plain of Lombardy. The latter division is highly productive in corn and in mulberry trees, as well as in flax, hemp, and oil. The wine is considered as good, but not sufficient for the domestic consumption. The mountainous parts afford iron, lead, copper, marble, granite, and charcoal. The manufactures consist principally of silk, but are considerable in woollen, linen, and cotton goods, and in iron, steel, glass, and paper wares. The capital, of the same name, is situated on the river Garza, at the foot of a hill, on the summit of which is a picturesque ancient castle. It contains, besides the cathedral, twelve parish and several conventual churches, six hospitals, six orphan-houses, and some other public buildings. The inhabitants amounted in 1817 to 34,168, but are stated to have increased to upwards of 40,000 in 1824. It is the chief seat of those fabrics the raw materials of which are so amply furnished by the province. Long. 10. 8. 4. E. Lat. 45. 32. 30. N.

BRESLAU, one of the governments into which the kingdom of Prussia is divided. It extends over the north-west part of the province of Silesia, or what was formerly Lower Silesia. It is bounded on the north and north-east by Posen, on the east by Poland, on the south-east by Oppeln, on the south-west by Reichenbach, and on the west by Liegnitz. Its extent is 5269 square miles, or 3,373,160 acres. The population amounted in 1817 to 792,071, at the end of 1819 to 833,253, and at the end of 1826 to 914,607. It is divided into twenty-two circles, which, in 1826, contained 121,080 houses, in thirty-five cities, seven market-towns, and 1283 villages. About two thirds of the inhabitants are of the Protestant profession, about one third Catholics, and betwixt 7000 and 8000 Jews. The live stock of the whole district consisted of 72,657 horses, 293,203 cows, and 894,460 sheep of all ages and both sexes. It forms the most important part of the province of Silesia, the greatest manufacturing country of the east of Europe. The city of Breslau is the capital as well of the government of that name as of the whole province of Silesia, and is the third of the royal residences. It is situated at the confluence of the Ohlau and the Oder, about 500 feet above the level of the Baltic Sea. It is the seat of the civil and military government of Silesia. A university, re-established in 1811, has a valuable library of 100,000 volumes, and in 1826 had 850 students, consisting of both Catholics and Protestants. It is an ancient city, exhibiting many specimens of the oldest German architecture. Many manufactures, particularly of linen and cloth, have long flourished there, though said to be now somewhat on the decline. At the great fair extensive transactions are carried on in fine wool. It contained, in 1826, 78,600 inhabitants, of whom 4600 were Jews. Long. 16. 56. 47. E. Lat. 51. 6. 50. N.

BRESSUIRE, an arrondissement in the department of the Two Sèvres, in France, extending over 650 square miles, and comprehending six cantons and ninety-one communes, with 68,400 inhabitants. The chief place is a market-town of the same name on the river Argenton. It was totally destroyed during the wars in La Vendée, but is beginning to recover from the losses of that period.

BREST, an arrondissement in the department of Finistère, in France, extending over 127 square miles, comprehending twelve cantons and eighty-five communes, with 136,149 inhabitants. It takes its denomination from the city of Brest, the most perfect and strongest naval station in the kingdom. The harbour consists of the road of Brest, with two deep indentations forming bays, into one of which the river Landeneau, and into the other the river Aulne, pour their streams. There is but one narrow en-

Breslau
Brest.

Bret
||
Brethren.

trance, defended by strong forts on both sides, and the interior is also protected by formidable batteries. The water is sufficiently deep for the largest ships, and there is space enough for 500 sail to ride securely. The docks, store-houses, and other appendages to the arsenal, are well adapted for the purpose intended. Brest was but a fishing village till 1631, since which it has risen to be an extensive and populous city, and contains at present 2600 houses, with 25,865 inhabitants. It is furnished with a medical school for the navy, an academy for the study of navigation, an observatory, a botanical garden, and a good library. Long. 4. 13. 20. W. Lat. 48. 22. 42. N.

BRET, a name which the people on the coast of Lincolnshire give to the common turbot, a fish extremely plentiful there, and taken in vast abundance. The way of catching them is in a net trailed on the ground by two horses, the one going up to the middle of his body in water, the other on shore.

BRETHREN AND SISTERS OF THE FREE SPIRIT, in *Ecclesiastical History*, an appellation assumed by a sect which sprung up towards the close of the thirteenth century, and gained many adherents in Italy, France, and Germany. They took their denomination from the words of St Paul, in his epistle to the Romans, chap. viii. ver. 2, 14, and maintained that the true children of God were invested with the privilege of a full and perfect freedom from the jurisdiction of the law. Some of their professed principles resembled those of the Pantheists, and they held that all things flowed by emanation from God; that rational souls were portions of the Deity; that the universe was God; that, by the power of contemplation, they were united to the Deity, and thereby acquired a glorious and sublime liberty, both from the sinful lusts and the common instincts of nature; and that the person who was thus absorbed in the abyss of the Deity, became a part of the Godhead, and was the son of God in the same sense and manner as Christ was, being freed from the obligation of all laws human and divine. Many edicts were published against this sect; but, notwithstanding the severities which they suffered, they continued till about the middle of the fifteenth century. They were called by several other names, such as Schwestriones, Picards, Adamites, and Turlupins.

BRETHREN and Clerks of the Common Life, a denomination assumed by a religious fraternity towards the latter end of the fifteenth century. They lived under the rule of St Augustin, and were eminently useful in promoting the cause of religion and learning. Their society was formed in the preceding century, by Gerard de Groot, a native of Deventer; but it did not flourish till about the period above mentioned, when it obtained the approbation of the council of Constance, and became very respectable in Holland, Lower Germany, and the adjacent provinces. It was divided into two classes; the *lettered brethren* or clerks, and the *illiterate*. They lived in separate habitations, but maintained the closest fraternal union. The former applied to the study of polite literature, and the education of youth; whilst the latter were employed in manual labour and the mechanic arts. They were frequently called Beghards and Lollards, by way of reproach.

White BRETHREN, Fratres Albati, were the followers of a leader about the beginning of the fifteenth century, who arrayed himself in a white garment; and as they also clothed themselves in white linen, they were distinguished by this title. Their leader was a priest from the Alps, who carried about a cross, like a standard, and whose apparent sanctity and devotion drew together a number of followers. This deluded enthusiast practised many acts of mortification and penance; endeavouring to persuade the European nations to renew the holy war, and pretend-

ing that he was favoured with divine visions. Boniface IX. ordered him to be apprehended and committed to the flames, upon which his followers dispersed.

BRETON, or CAPE BRETON, an island near the eastern side of the continent of North America, situated between forty-five and forty-seven degrees of north latitude. It is separated from Nova Scotia by a narrow strait called Canso, and is about a hundred miles in length by fifty in breadth. It is surrounded with little sharp-pointed rocks, separated from each other by the waves, above which some of their tops are visible. All its harbours are open to the south-east. On the other parts of the coast there are but few anchoring places for small vessels. Except in the hilly portions, the surface of the country has but little solidity, being everywhere covered with a light moss, and with water. The dampness of the soil is exhaled in fogs, without rendering the air unwholesome; but the climate is very cold, owing either to the number of the lakes, which cover more than half the island and remain frozen for a considerable period of the year, or to the extent of the forests, and the fogs that totally intercept the rays of the sun.

Though some fishermen had long resorted to this island every summer, not more than twenty or thirty ever settled there. The French, who took possession of it in August 1713, were properly the first inhabitants. They changed its name to that of Isle Royale, and fixed upon Fort Dauphin as their principal settlement. This harbour was two leagues in circumference, and might have been rendered impregnable at a trifling expense; but the difficulty of approaching it occasioned it to be abandoned, after great labour had been bestowed upon the undertaking. The settlers then turned their views to Louisbourg, the access to which was easier; and convenience was thus preferred to security. The fortification of Louisbourg, however, was not begun till the year 1720.

In the year 1714 some fishermen, who till then had lived in Newfoundland, settled in this island. It was expected that their number would soon have been increased; but these hopes were disappointed. Some distressed adventurers from Europe, however, came over from time to time to Cape Breton, and the number of inhabitants gradually increased to four thousand. They were settled at Louisbourg, Fort Dauphin, Port Toulouse, Nerucka, and on all the coasts where a proper beach was to be found for drying cod. The inhabitants never applied themselves to agriculture, the soil being wholly unfit for it. They frequently sowed corn, but it seldom came to maturity; and when it did thrive so as to be worth reaping, it degenerated so much that it was unfit for seed next harvest. In a word, the soil of Cape Breton seemed calculated to invite none but fishermen and soldiers.

Though the island was entirely covered with forests before it was inhabited, its woods scarcely ever became an object of trade. The peltry trade was a very inconsiderable object. It consisted only of the skins of a few lynxes, elks, musk-rats, wild cats, bears, otters, and foxes of a red and silver-gray colour. Some of these were procured from a colony of Mickmac Indians who had settled on the island with the French, and never could raise more than sixty men able to bear arms. The rest came from St John's, or the neighbouring continent. Greater advantages might possibly have been derived from the coal-mines, which abound in the island. The strata lie in a horizontal direction; and being only about eight feet below the surface, they may consequently be worked without digging deep or draining off the waters. But notwithstanding the prodigious demand for coal from New England between the year 1745 and 1749, these mines would probably have been forsaken, had not the ships which were sent out to the French islands wanted ballast.

Brev. The people of Cape Breton did not send all their fish to Europe. Part was exported to the French southern islands, on board twenty or twenty-five ships of from seventy to a hundred and forty tons burden. Besides the cod, which formed at least half their cargoes, they exported to the other colonies timber, planks, thin oak-boards, salted salmon, and mackerel, train-oil, and sea-coal, which were paid for in sugar and coffee, but chiefly in rum and molasses. The island, however, could not consume all these commodities, and as Canada took but a small part of the overplus, it was chiefly bought by the people of New England, who gave in exchange fruits, vegetables, wood, brick, and cattle.

This island, which may be considered as the key of Canada, was attacked by the English in 1745. The plan of the invasion was laid at Boston, and New England bore the expense of it. A merchant named Pepperel, who had excited, encouraged, and directed the enterprise, was intrusted with the command of an army of 6000 men, which had been levied for the expedition; and these forces, conveyed by a squadron from Jamaica, brought the first news to Cape Breton of the danger that threatened it. But although the advantage of a surprise would have secured the landing without opposition, and the invaders had to encounter but 600 regular troops and 800 inhabitants hastily armed, still the success of the undertaking was precarious. Little could be expected from a militia suddenly assembled, who had never seen an enemy, and who were to act under the direction of sea-officers only. But an incident, fortunate for the invaders, neutralized even this insufficient force.

The construction and repairs of the fortifications of Louisbourg had always been left to the care of the garrison, and the soldiers were anxious to be employed in these works. But when they found that those who should have paid them appropriated to themselves the profit of their labours, and when the justice they demanded was denied them, they determined to assert their rights, and their indignation rose to such a height that they despised all authority. They had in fact been in open rebellion for six months, when the British appeared before the place. This apparition, however, did not produce the union which was so necessary for the common defence. The soldiers indeed made advances; but their commanders, mistrusting a generosity of which they themselves were incapable, kept their men in a manner prisoners, till an ill-managed defence had reduced them to the necessity of capitulating. The whole island shared the fate of Louisbourg, its only bulwark.

This valuable possession, restored to France by the treaty of Aix-la-Chapelle, was again attacked by the British in 1758. On the 2d of June, a fleet of twenty-three ships of the line and eighteen frigates, having on board 16,000 troops, anchored in Gabarus Bay, within half a league of Louisbourg. It had been attempted to render the landing impracticable near the town; and in the prudent precautions which had been taken, the besiegers saw the dangers and difficulties they had to expect; but, far from being deterred by these, they had recourse to stratagem, and, extending their line so as to threaten the whole coast, they landed by force of arms at Cormorant Creek. This place was naturally weak. The French had fortified it with a good parapet planted with cannon, behind which they had posted 2000 soldiers and some Indians, while in front they had constructed with felled trees an impenetrable abbattis.

But these and other precautions that had been taken were rendered abortive by the impetuosity of the French. The English had scarce begun to move towards the shore, when their enemies exposed the snare they had laid for

them. By opening a brisk but hasty fire on the boats, and still more by prematurely removing the boughs that masked the forces, the English, apprised of their danger, immediately turned back, and the benefit of these preparations was entirely lost. The situation of the English, however, was still sufficiently critical, especially as they saw no other place to effect a landing on except a rock, which had always been deemed inaccessible. But General Wolfe, while occupied in reembarking his troops, and sending off the boats, ordered Major Scott to repair thither; and that officer immediately proceeded towards the spot with his men. The Major's own boat approached first, but sinking at the very instant he stepped ashore, he climbed up the rock alone, in hopes of meeting with a hundred of his men who had been sent to attempt a landing at another point. Instead of this number, he found only ten; but with these few he gained the summit of the rock, where ten Indians and sixty Frenchmen killed two of them and mortally wounded three. But notwithstanding this loss he stood his ground under cover of a thicket, till the troops, regardless alike of the raging surf and the fire of the cannon, came up to him and put him in full possession of that important post, the only one that could secure the landing. The French, as soon as they saw that the enemy had got a firm footing on land, betook themselves to the only remaining refuge, and shut themselves up in Louisbourg. But the fortifications were in a bad condition; the revêtements of the several curtains had entirely crumbled away; there was but one casemate and a small magazine that were bomb-proof; and the garrison consisted only of 2900 men. Notwithstanding these disadvantages, however, the besieged made an obstinate resistance; and it was only on the eve of an assault, which it was impossible to sustain, that they talked of surrendering. An honourable capitulation was granted them, and the possession was confirmed to Great Britain by the peace in 1763, after which the fortifications were blown up, and the town of Louisbourg dismantled.

BREVET, in the French customs, denotes the grant of some favour or donation from the king.

BREVET more particularly denotes that species of military commission by which an officer is promoted to a rank in the army above that which he holds in his regiment. Brevet rank, therefore, is a rank in the army higher than that for which pay is received, and, when corps are brigaded, it gives precedence according to the date of the brevet commission. The term *brevet* is also sometimes used to express general promotion, by which a given number of officers are raised from the rank of captain upwards, without any additional pay.

BREUGHEL, JOHN, was born about the year 1575. He first applied himself to painting flowers and fruit, in which he excelled; and he afterwards obtained much success in drawing landscapes and views of the sea. He lived long at Cologne, where he acquired considerable reputation, and then travelled into Italy, where his fame went before him, and where his landscapes, adorned with small figures, gave very great satisfaction. If a judgment may be formed from the number of pictures he left behind him, he must have been exceedingly industrious; nor was he satisfied with embellishing his own works, but rendered himself useful in this respect to his friends. Even Rubens made use of Breughel's hand in the landscape part of several of his small pictures; such as his *Vertumnus* and *Pomona*, the satyr viewing the sleeping nymph, and the terrestrial paradise, which is looked upon as the masterpiece of that great artist. Breughel died in 1642.

BREVIARY, a daily office or book of divine service in the Roman church. It is composed of matins, lauds, vespers, and the compline or *post communio*.

The breviary of Rome is general, and may be used in

Brevet
||
Breviary.

Breviary all places; but on the model of this various others have been formed, appropriated to each diocese, and each order of religious persons.

The breviary of the Greeks is the same in almost all churches and monasteries which follow the Greek rites; and they divide the psalter into twenty parts. In general, the Greek breviary consists of two parts; the one containing the office for the evening; the other that of the morning, divided into matins, lauds, first, third, sixth, and ninth vespers, and the compline, that is, of seven different hours, on account of the saying of David, *Septies in die laudem dixi tibi*.

The institution of the breviary is not very ancient, and there have been inserted in it the lives of the saints, full of stories more remarkable for their strangeness than their authenticity. This gave occasion to several reformations by different councils, especially those of Trent and Cologne; by several popes, particularly Pius V. Clement VIII. and Urban VIII.; and also by several cardinals and bishops, each lopping off some extravagance, and bringing it nearer to the simplicity of the primitive offices. Originally, all were obliged to recite the breviary every day; but by degrees the obligation was restricted to the clergy only, who are enjoined, under penalty of mortal sin and ecclesiastical censures, to recite it at home when they cannot attend in public. In the fourteenth century a particular reservation was granted in favour of bishops, who were allowed, on extraordinary occasions, to pass three days without rehearsing the breviary.

This office was originally called *cursus*, and afterwards *breviarium*, which imports that the old office was abridged, or rather, that this collection is a kind of abridgment of all the prayers. The breviaries now in use are innumerable;

able; the difference between them consists principally in the number and order of the psalms, hymns, paternosters, ave-Marias, creeds, magnificates, cantemuses, benedictuses, canticamuses, nunc dimittises, misereres, hallelujahs, gloria-patris, and so on.

BREVIARY, in *Roman Antiquity*, a book first introduced by Augustus, containing an account of the application of the public money.

BREVIATOR, an officer under the eastern empire, whose business it was to write and translate briefs. At Rome those are styled *breviators*, or *abbreviators*, who dictate and draw up the pope's briefs.

BREWER, ANTHONY, a dramatic poet, who flourished in the reign of King Charles I., and appears to have been held in considerable estimation by the wits of that time, as may be gathered from a compliment paid to him in a poem called *Steps to Parnassus*, in which he is supposed to have a magic power to call the muses to his assistance, and is even set on an equality with Shakspeare himself. There are, however, great disputes among the several writers as to the number of his works. Those which have been ascribed to him with any certainty are, 1. The Country Girl, a comedy; 2. The Love-sick King, a comedy; and, 3. *Lingua*. When this play was performed at Cambridge, it is said by Winstanley that Oliver Cromwell, then a youth, acted a part in it. The substance of the piece is a contention among the Senses for a crown, which *Lingua* had laid for them to find. The part allotted to young Cromwell was that of Tactus or Touch.

BREWER, a person who professes the art of brewing. There are companies of brewers in most capital cities; that of London was incorporated in 1427 by Henry VI.

BREWING.

WE shall divide this article into five chapters. In the first we shall take as short a view as possible of the history of the art; in the second, we shall give an account of the different kinds of grain employed in brewing; in the third, we shall treat of the process of malting; in the fourth, of that of brewing; and in the fifth, we shall give an account of the nature and properties of the different kinds of ale and beer manufactured by the brewer. The *Explanation of the Plates* will contain a description of the vessels used in a London porter brewery.

CHAP. I.

HISTORY OF BREWING.

No notice is taken of beer or ale in the books of Moses, from which it is probable that they were unknown till after the death of this legislator. All the ancient Greek writers agree in assigning the honour of the discovery of beer to the Egyptians, whose country, being annually inundated by the Nile, was not adapted to the cultivation of vines. Herodotus, who wrote about 450 years before the commencement of the Christian era, informs us that the Egyptians made their wine from barley, because they had no vines. *Οἶνον δ' ἐκ κριθῶν πεποιημένον διαχρῆνται οὐ γὰρ σῆν εἶσι ἐν τῇ χώρῃ αὐπῆλοι.* Herodoti, lib. ii. c. 78. Pliny says that this liquid in Ægypt was called *zythum* (Plinii *Hist. Nat.* lib. xxii. c. 25). The same name was given to it by the inhabitants of Galatia, who, according to Diodorus Siculus, were unable to cultivate grapes on account of the coldness of their climate. Beer was distinguished among the Greeks by a variety of names. It was called *οἶνον κριθίνον* (barley wine) from its vinous properties, and from the material employed in its formation. In Sophocles,

and probably in other Greek writers, it is distinguished by the name of *βρυτον*. Dioscorides describes two kinds of beer, to one of which he gives the name of *ζυθον*, and to the other *κωρημι*; but he gives us no description of either sufficient to enable us to distinguish them from each other. (Dioscorides, lib. ii. c. 79 and 80.) Both, he informs us, were made from barley, and similar liquids were manufactured in Spain and Britain from wheat.

Tacitus informs us, that, in his time, beer was the common drink of the Germans; and from his imperfect description of the process which they followed, it is not unlikely, or rather there can be no doubt, that they were acquainted with the method of converting barley into malt. "Potui humor ex hordeo aut frumento in quadam similitudinem vini corruptus." (*De Moribus German.* c. 23.) Pliny gives us some details respecting beer, though they are by no means satisfactory. He distinguishes it by the name of *cerevisia* or *cervisia*, the appellation by which it is always known in modern Latin books.

This liquid does not appear to have come into general use in Greece or Italy; but in Germany and Britain, and some other countries, it appears to have been the common drink of the inhabitants, at least as early as the time of Tacitus, and probably long before. It has continued in these countries ever since, and great quantities of beer are still manufactured in Germany, in the Low Countries, and in Britain.

The first treatise published on the subject, as far as we know, was by Basil Valentine. This treatise, according to Boerhaave, for we ourselves have never had an opportunity of seeing it, is both accurate and elegant. In the year 1585, Thaddeus Hagecius ab Hayck, a Bohemian writer, published a treatise entitled *De Cervisia*

ejusque conficiendi ratione, natura, viribus et facultatibus. This little treatise, consisting only of fifty pages, is written with great simplicity and perspicuity, and gives as accurate a description of the whole process of brewing as any treatise on the subject which we have seen. In the early part of the eighteenth century, Mr Combrune, who, we believe, was a practical London brewer, published a book entitled *The Theory and Practice of Brewing*. This book has gone through many editions, and, we believe, is still reckoned the standard book on the subject. But the attempts made in it to give a rational theory of brewing are far from being satisfactory. Nor can any stress be laid upon the experiments which it contains on the colour of malt, according to the temperature at which it is dried. The fact is, that malt may be rendered brown, or even black, by exposure to a very low heat; while it may be exposed to a very considerable temperature without losing its colour. The writer of this article has seen malt exposed on the kiln to a heat of 175° without losing its colour, or without being deprived of the power of vegetating when put into the ground; and he has reason to believe that these properties would have remained unaltered had the temperature been raised still higher. It is not the degree of heat applied, but the rapidity with which it is raised, that darkens the colour of malt. If the heat at first does not exceed 100°, and if, after the malt is dried as much as it can be at that temperature, the heat be raised to 120°, kept some time at that temperature, and then raised gradually higher, and if we continue to proceed in this manner, the temperature of the kiln may be elevated at least to 175° without in the least discolouring the malt.

In the year 1784 Mr Richardson of Hull published his *Theoretic Hints on Brewing Malt Liquors*, and his *Statistical Estimates of the Materials of Brewing, showing the Use of the Saccharometer*. These books are reprehensible, on account of the air of mystery in which the subject is invested, and the avowal of the author, that he conceals certain parts of the processes. If a brewer conceives he knows more of his art than his neighbours, and chooses to keep his knowledge to himself, there is nothing to be said; but if he publish a book upon the subject, and yet persists in his concealment, he deserves no quarter. His book, in such a case, can be looked upon in no other light than as a quack bill to advertise the goodness of his wares. Mr Richardson, however, deserves considerable praise for the *saccharometer*, which he appears to have been the first to bring under the notice of the brewer. This instrument is of material service, by making brewers acquainted with the strength of their worts, and consequently with the proportion of soluble matter which is furnished by the materials that they employ. Mr Richardson's *saccharometer*, indeed, was not accurate, because it was founded on an erroneous principle. The method which he followed was to determine the weight of a barrel of pure water. The liquid being then converted into wort, a barrel of it was weighed again, and the increase of weight was considered as the matter which the water held in solution. Mr Richardson did not seem to be aware that, when water dissolves the sweet portion of malt, its bulk is altered; and that, for this reason, the specific gravity of it does not indicate the quantity of solid matter which it holds in solution. A set of experiments made on purpose, by dissolving determinate weights of the solid extract of malt in given quantities of water, is necessary to determine the point. The same objection applies to the *saccharometer* of Dring and Fage, and to various others in common use. That of Dica's is nearly correct, having been constructed upon proper principles. But perhaps the best is one constructed about twenty-five years ago by Dr Thomson, and used by the excise officers in Scotland. It indicates the specific gra-

vity of the wort; from which, by means of a sliding rule, which accompanies the instrument, the weight of saccharine matter contained in it is at once determined.

One of the latest books on the subject which we have seen is entitled *Practical Treatise on Brewing and Distilling*. This book was published in quarto in the year 1805. The author, whose name is Shannon, appears to have had some practical knowledge of brewing; but he must have been extremely illiterate, as he was totally unable to write either grammar or common sense. The book is a tissue of absurdities from beginning to end; and the impracticability of his proposed improvements is surpassed only by the absurdity of his theory, which consists of scraps and sentences, taken out of chemical books, and tacked together, so as to have no meaning whatever.

CHAP. II.

OF THE KIND OF GRAIN USED BY BREWERS.

Every kind of grain, with perhaps hardly an exception, may be employed for the purposes of the brewer. In America it is not uncommon to make beer with the seeds of Indian corn or *zea mais*. In order to convert it into malt, it is found necessary to bury it for some time under the ground; and when germination has made sufficient progress, it is dug up and kiln-dried. (See *Philosophical Transactions*, vol. xii. p. 1065.) Mr Mungo Park informs us, that, in Africa, the negroes make beer from the seeds of the *Holcus spicatus*, and the process employed, as he describes it, seems to differ but little from the one followed in this country. (See *Park's Travels*, p. 63, 8vo edition. Dioscorides assures us, that in Spain and Britain wheat was employed for the manufacture of beer; and the writer of this article has been informed by a gentleman in the service of the East India Company, that he has made beer from wheat at Madras. We have ourselves seen oats employed for this purpose in Great Britain; and in Germany and the north of Europe we believe that it is not uncommon to employ rye for the same purpose. But the material which answers best, and which is almost solely used in Great Britain, and we believe in every part of Europe where beer is manufactured, is barley.

Barley is the seed of the *Hordeum vulgare*, a plant species of which has been cultivated from time immemorial, chiefly barley. for the manufacture of beer. There are two species of *hordeum* under cultivation in Britain. The first is, the *Hordeum vulgare*, or barley in which the seeds are disposed in two rows on the spike. This is the species usually cultivated in England and in the southern parts of Scotland. The second is the *Hordeum hexastichon*, called in the south of Scotland *bear*, and in Aberdeenshire *big*. In this species, the grains are disposed in two rows, as in the other; but three seeds spring from the same point, so that the head of *big* appears to have the seeds disposed in six rows. *Big* is a much more hardy plant than barley, and ripens more rapidly. Hence it thrives better than barley in cold and high situations. On this account it is sown in preference in the Highlands and northern parts of Scotland, where the climate is colder than farther to the south. We have been assured that there is a third species of *hordeum* cultivated in Scotland, in which the seeds in the spike are arranged in four rows. To this the term *bear* is exclusively confined by some. We have not ourselves had an opportunity of seeing this species, nor do we find it noticed by botanists. The trivial name *tetrastichon* might be applied to it.

The grains of barley are much larger than those of *big*, and the cuticle which covers them is thinner. Indeed the thickness of the skin of barley itself varies according

Brewing. to the heat of the climate in which it is cultivated, being always the thinner the warmer the climate. Thus it will be found that the cuticle of Norfolk barley is thinner than that of Berwickshire or East Lothian barley; and if Norfolk barley be sown in Scotland for several successive years, its cuticle will be found to become thicker.

Its specific gravity. The specific gravity of barley is rather greater than that of big. The specific gravity of barley, tried in more than 100 different specimens, was found by us to vary from 1.333 to 1.250, and that of big from 1.265 to 1.227. The average weight of a Winchester bushel of barley was found to be 50.7 lbs. avoirdupois, and the average weight of a bushel of big 46.383 lbs. The heaviest barley tried weighed 52.265 lbs. per bushel, and the heaviest big weighed 48.586 lbs. The big grew in Perthshire, and the season was peculiarly favourable. It was not absolutely free from a mixture of barley, as was ascertained by sowing a quantity of it, but the proportion of barley was very small. The average weight of a grain of barley is 0.6688 grain, or very nearly two-thirds of a grain, while the average weight of a grain of big is 0.5613 grain. The average length of a grain of barley, from many thousand measurements, is 0.345 inch, while that of a grain of big is 0.3245 inch. So that the average of both would give us very nearly the third of an inch, which it ought to do, according to the origin of our measures, as commonly stated. The average breadth of a grain of barley is 0.145 inch, while the average breadth of a grain of big is 0.136 inch. The average thickness of a grain of barley is 0.1125 inch, while the average thickness of a grain of big is 0.1055 inch. Thus we perceive that the grain of big is smaller than the grain of barley in all its dimensions.

Weight of the husk. To determine the relative weight of the skins of barley and big, we made choice of three parcels of grain, all excellent in their kinds, namely, Norfolk barley, Haddington barley, and Lanark big. The weights of the whole grain, and of the cuticles of each of these, were as follows:

	Weight of a corn in grains.	Weight of cuticle in grains.
Norfolk barley.....	0.6809.....	0.110 or $\frac{1}{9}$
Haddington barley.....	0.7120.....	0.123 or $\frac{1}{8}$
Lanark big.....	0.5408.....	0.125 or $\frac{1}{8}$

From this we see that there is little difference between the weight of the skin of Norfolk and Haddington barley, but a very considerable difference between Haddington barley and Lanark big. Hence it would seem that this difference is not owing to the climate in which the barley vegetates, but rather to the nature of the two species.

Bulk. The bulks of these two species of grain with relation to each other are as follows:

Barley.....	0.00217 cubic inch.
Big.....	0.001777 cubic inch.

These quantities represent the average bulk of a corn of each kind. Thus it appears that a grain of barley is rather more than $\frac{1}{4}$ th part larger than a grain of big.

Finally, from a comparison of many thousand corns of each species with each other, it appears that the inequality between the size of different grains of big is greater than that between different grains of barley. Indeed, if we

examine an ear of big when nearly ripe, we shall perceive that the corns towards the bottom of the ear are smaller than those towards the summit and about the middle of the ear. Several of these bottom grains are usually abortive, or consist only of skin; but this is not always the case. In an ear of barley, on the contrary, we shall find almost all the grains nearly of a size, though in some cases the grain constituting the upper termination of the spike is rather smaller than the rest.

These circumstances may strike the reader as too minute and trifling to be stated in such detail; but we shall find afterwards that they will furnish us with an explanation of some anomalous circumstances which occur when these two species of *hordeum* are converted into malt. The value of barley, or its produce in alcohol, is rather improved, while big, on the contrary, is deteriorated, by malt-ing it, at least twenty per cent.

The constituents of the kernel of barley and big, as far as we are able to ascertain at present, are the same. Barley has been subjected to an elaborate chemical analysis by Einhoff, who obtained from 3840 parts of barley-corns the following constituents:

Volatile matter.....	430
Husk or cuticle.....	720
Meal.....	2690

3840

From the same quantity of barley-meal he obtained,	
Volatile matter.....	360
Albumen.....	44
Saccharine matter.....	200
Mucilage.....	176
Phosphate of lime with mucilage.....	9
Gluten.....	135
Husk, with some gluten and starch.....	260
Starch, not quite free from gluten.....	2580
Loss.....	76

3840

The writer of this article has likewise extracted from barley, by means of alcohol, a small quantity of an oily matter, which has an asparagus green colour, and does not burn with the same readiness as an oil. It has very much the appearance of olive oil coagulated, but its consistence is less, and its colour is darker. It has little smell, and its taste resembles the flavour of spirits from raw grain. We have likewise found in big a quantity of nitrate of soda. Hence it is likely that this salt exists as a common constituent of barley. We obtained it by steeping big in water for two days, concentrating the liquid, and setting it aside in a dry place. Many rhomboidal crystals of nitrate of soda gradually make their appearance as the liquid evaporates.

We shall terminate this chapter by a table, exhibiting the most remarkable properties of a considerable number of specimens of British barley and big, as determined by the writer of this article. The different specimens are distinguished by the name of the county in which they grew. By the *bushel* in the table is meant the Winchester bushel of 2150.42 cubic inches.

TABLE OF PROPERTIES.

CHAP. III.

OF MALTING.

It is always customary to convert barley into malt before employing it in the manufacture of ale. Not that this conversion is absolutely necessary, but that it adds considerable facility to the different processes of the brewer. The writer of this article has several times tried the experiment of making ale from unmalted barley, and found it perfectly practicable. Several precautions, however, are necessary in order to succeed. The water let upon the ground barley in the mash-tun must be considerably below the boiling temperature; for barley-meal is much more apt to *set* than malt, that is, to form a stiff paste, from which no wort will separate. The addition of a portion of the chaff of oats serves very much to prevent this *setting of the goods*, and facilitates considerably the separation of the wort. Care must likewise be taken to prevent the heat from escaping during the mashing, and the mashing must be continued longer than usual; for it is during the mashing that the starch of the barley is converted into a saccharine matter. This change seems to be owing merely to the chemical combination of a portion of water with the starch of the barley; just as happens when common starch is converted into sugar, by boiling it with very dilute sulphuric acid, or any other acid. This method of brewing from raw grain answers admirably for small beer. Some years ago it was practised to a considerable extent by several brewers of small beer in Edinburgh, and their beer was considered as greatly preferable to small beer brewed in the usual manner. The practice was stopped by a decision of the Court of Exchequer,—a decision which, in our opinion, proceeded upon arbitrary grounds, and which was at all events detrimental to the public; for surely it is highly impolitic to prevent ameliorations in the manufactures in order to guard against any deficiency in the produce of the taxes. A wise government would have permitted the improvement, and would have levied the malt-tax in a different manner. In our trials the raw barley did not answer so well for making strong ale as for small beer. The ale was perfectly transparent, and we kept it for several years without its running into acidity; but it had a peculiar flavour, by no means agreeable. Probably a little practice might have enabled us to get rid of this flavour, in which case raw grain would answer in every respect as well for brewing as malt does.

A duty was first charged upon malt during the troubles of Charles I.'s reign. But it continued very moderate till the war with France recommenced in 1803. It was then raised to the following sums per bushel:—

	L.	s.	d.	
English malt.....	0	4	4	or 100
Malt of Scotch barley.....	0	3	8½	or 84·856
Malt of Scotch big.....	0	3	0½	or 69·472

But two shillings of this tax were to continue only till the end of the war, and for six months after its conclusion. In consequence of this very heavy tax, several regulations were imposed upon the maltster, with a view to facilitate the levying of the duty, and to prevent him from defrauding the revenue. The most important of these are the two following:—1. The barley must remain in the cistern in which it is steeped with water for a period not less than forty hours. 2. When the malt is spread upon the floor the maltster is not at liberty to sprinkle any water upon it, or to moisten the floor. We shall now describe the process of malting, as it is practised by the best-informed malt-makers in Great Britain.

Malting consists of four processes, which follow each other in regular order; namely, *steeping*, *couching*, *flooring*, and *kiln-drying*.

1. The steep is a square cistern sunk at one end of the malt barn, lined with stone, and of a sufficient size to hold the whole barley that is to be malted at a time. The bar-ley is put into this cistern with the requisite quantity of pure water to cover it. It is laid as evenly as possible upon the floor of the cistern. Here it must remain at least forty hours; but in Scotland, especially when the weather is cold, it is customary to allow it to remain much longer. We have seen barley steeped in Edinburgh for 112 hours by one maltster, and by another usually ninety-eight or ninety-two hours. It is the common practice to introduce the water into the cistern before the barley, and it is usually once drawn off and new water added during the steeping.

Three changes take place on the barley while in the steep. 1. It imbibes moisture and increases in bulk. 2. Some carbonic acid gas is evolved, most of which remains dissolved in the steep-water. 3. A portion of the husk or skin of the barley is dissolved, in consequence of which the steep-water acquires a yellow colour, and contracts a peculiar smell, not unlike that of moist straw.

The quantity of moisture imbibed by the barley varies according to the goodness of the barley and the length of time during which it is allowed to remain in the steep. But the general average may be stated at 0·47; or 100 lbs. of barley, steeped the usual time, weigh, newly taken out of the steep and dried, 147 lbs. English barley acquires more weight than Scotch barley, while Scotch barley acquires greater weight than big. But big cannot safely be steeped for so long a time as barley. The swell of the grain in the steep obviously depends upon the quantity of water absorbed; but it is not so great as that absorption, scarcely ever exceeding one fifth of the original bulk of the barley, while the increase of weight amounts to nearly one half of that of the original weight of the grain. The result of a good many trials by the writer of this article gives the bulk of one hundred measures of different kinds of barley, after steeping, as follows:—

English barley.....	124	measures.
Scotch barley.....	121·1	
Scotch big.....	118	

The greatest swell observed was from 100 to 183, which took place in barley from the county of Suffolk; the smallest was from 100 to 109, which took place in Perth big.

While the malt is in the steep cistern it is repeatedly gauged by the exciseman, and the duty on the malt is levied by what is called the best gauge, or that which gives the greatest bulk of grain. It is in his power likewise to determine the quantity of malt in the subsequent processes, and, if any of them exceeds the best gauge in the cistern, to levy the duty by it. But these subsequent gauges are not susceptible of the same precision as the gauges in the cistern, when the grain is surrounded on all sides by perpendicular walls.

That carbonic acid is evolved during the steeping of grain, is obvious from the most simple experiments. If the steep-water be mixed with lime-water, the whole becomes milky, and carbonate of lime is deposited. If the steep-water be agitated, it froths on the surface like ale. If it be heated, it gives out carbonic acid gas, which may be collected over mercury. But we never were able to observe bubbles of gas extricate themselves from the grain during the steep, except once or twice during warm weather, when the steep-water was allowed to remain rather too long without being changed. In these cases, something like a commencement of fermentation, or perhaps of putrefaction, appeared to take place. But in general, there is reason to believe that nearly all the carbonic acid evolved in the steep remains in solution in the water, or

at least is extricated from the water in an imperceptible manner. From the observations of Saussure, it seems probable that the formation of carbonic acid in the steep is owing to the oxygen gas held in solution by the steep-water.

The steep-water gradually acquires a yellow colour, and the peculiar smell and taste of water in which straw has been steeped. At the same time, the barley becomes whiter, showing clearly that the water has absorbed a portion of colouring matter which existed in the husk or skin of the grain. The average quantity of matter dissolved by the water amounts to about $\frac{1}{70}$ th of the weight of the barley. The steep-water becomes much more deeply coloured when big is steeped in it than it does with barley, because big is darker in the colour, and its husk is thicker and contains more colouring matter. The matter of big taken up by the steep-water amounts to about $\frac{1}{40}$ th of the weight of the whole grain. When this steep-water is evaporated it leaves a matter of a yellow colour and disagreeably bitter taste, which deliquesces in a moist atmosphere. The only salt which it contains in any notable quantity is nitrate of soda.

Thus the only notable alterations which the kernel of barley undergoes in the steep are the absorption of water and the resulting increase of bulk. The matter taken up by the water seems to proceed only from the skin, and the evolution of carbonic acid may perhaps be owing to some commencement of alteration which this dissolved matter experiences. It can scarcely be ascribed to any change going on within the kernel itself.

2. When the barley is judged by the maltster to have remained long enough in the steep, which is the case when its two ends can be easily squeezed together between the finger and the thumb, the water is let off and the grain allowed to drain. It is then thrown out of the cistern upon the malt floor, where it is formed into as regular a rectangular heap as possible, which is called the *couch*. While in this position it is gauged by the exciseman, and if it measure more than it did in the steep, he is at liberty to charge the duty upon the quantity to which the grain now amounts. But as the barley in the couch cannot be rendered perfectly regular, it requires a good deal of skill and considerable attention to gauge it with tolerable accuracy. On that account the duty we believe is levied from the couch gauge. The grain is allowed to remain in the couch without any alteration for about twenty-six hours.

3. If we plunge a thermometer into the grain, and observe it from time to time, we shall find that the barley continues for some hours without acquiring any perceptible increase of heat. During this period the moisture on the surface of the corns gradually exhales or is absorbed, so that they do not perceptibly moisten the hand. But at last the thermometer begins to rise, and continues to do so gradually till the temperature of the grain is about ten degrees higher than that of the surrounding atmosphere. This happens usually in about ninety-six hours after it has been thrown out of the steep. It now exhales an agreeable odour, which has some resemblance to that of apples. If we thrust our hand into the heap we shall find that it feels warm, while, at the same time, it has become so moist as to wet the hand. The appearance of this moisture is called *sweating* by the maltsters, and it constitutes a remarkable period in the process of malting. We have reason to believe that a little alcohol is at this period exhaled by the grain.

If we examine the grains in the inside of the heap at the time of sweating, we shall perceive the roots beginning to make their appearance at the bottom of each seed. At first they have the appearance of a white prominence,

which soon divides itself into three rootlets. In big the number of rootlets seldom exceeds three, but in barley it frequently amounts to five or six. These rootlets increase in length with great rapidity, unless their growth be checked by artificial means; and the principal art of the maltster is directed to keep them short till the grain be sufficiently malted. The writer of this article has seen them increase in length nearly to two inches in the course of a single night; and when he purposely favoured the growth, in order to ascertain the effect upon the malt, he has seen them get to the length of three inches or more. In such cases, the heat of the grain rose very rapidly, and on one occasion was little inferior to eighty degrees. Indeed it is probable that, if not checked, the temperature would rise sufficiently high to char the grain, if not to set it on fire.

The too great growth of the roots, and the too high elevation of temperature, is prevented by spreading the grain thinner upon the floor, and carefully turning it over several times a day. At first the depth is about sixteen inches; but this depth is diminished a little at every turning, till at last it is reduced to three or four inches. The number of turnings is regulated by the temperature of the malt, but they are seldom fewer than two each day. In Scotland the temperature of the grain is kept as nearly as possible at fifty-five degrees; but in England we have generally found the temperature of the grain on the malt floor about sixty-two degrees. It has been generally supposed that the Hertfordshire method of making malt is the best; but, after a very careful comparison of the two methods, we were unable to perceive any superiority whatever in the English mode.

About a day after the sprouting of the roots, the rudiment of the future stem begins to make its appearance. This substance is called by the maltsters the *acrospire*. It rises from the same extremity of the seed with the root, and, advancing within the husk or skin, would at last (if the process were continued long enough) issue from the other extremity in the form of a green leaf; but the process of malting is stopped before the acrospire has made such progress.

While the grain is on the malt floor, it has been ascertained that it absorbs oxygen gas and emits carbonic acid gas; but to what amount these absorptions and emissions take place, has not been ascertained. They are certainly small; for the average loss which the grain sustains when on the malt floor is only three per cent., a considerable portion of which must be ascribed to roots broken off, and grains of barley bruised during the turning. As the acrospire shoots along the grain, the appearance of the kernel or mealy part of the corn undergoes a considerable change. The glutinous and mucilaginous matter in a great measure disappears, the colour becomes whiter, and the texture so loose that it crumbles to powder between the fingers. The object of malting is to produce this change. When it is accomplished, which takes place when the acrospire has come nearly to the end of the seed, the process is stopped altogether.

At this period, it was formerly the custom in Scotland to pile up the whole grain into a pretty thick heap, and allow it to remain for some time. The consequence is the evolution of a very considerable heat, while, at the same time, the malt becomes exceedingly sweet. But this plan is now laid aside, because it occasions a sensible diminution in the malt, without being of any essential service; for the very same change takes place afterwards, while the malt is in the mash-tun, without any loss whatever.

The time during which the grain continues on the malt-floor varies according to circumstances. The higher the

Brewing.

Brewing. temperature at which the grain is kept, the more speedily is it converted into malt. In general, fourteen days may be specified as the period which intervenes in England from throwing the barley out of the steep till it is ready for the kiln; while in Scotland it is seldom shorter than eighteen days, and sometimes three weeks. This, no doubt, is an advantage in favour of English malting, as every thing which shortens the progress, without injuring the malt, must turn out to the advantage of the manufacturer.

Kiln-drying.

4. The last part of the process is to dry the malt upon the kiln, which stops the germination, and enables the brewer to keep the malt for some time without injury. The kiln is a chamber, the floor of which usually consists of iron plates full of holes, and in the roof there is a vent to allow the escape of the heated air and vapour. Under this room is a space in which fire of charcoal or coke is lighted. The heated air which supplies this fire passes up through the holes in the iron plates, and makes its way through the malt, carrying off the moisture along with it. At first the temperature of the malt is not higher than 90°; but it is elevated very slowly to 140°, or even higher. We believe that in many cases it rises at last almost as high as 212°, though we have never witnessed any such high temperature ourselves. But we have seen pale malt dried at a temperature of 175°, without any injury whatever. The great secret in drying malt properly consists in keeping the heat very low at first, and only raising it very gradually as the moisture is dissipated. For a high temperature applied at first would infallibly blacken, or even char the malt, and would certainly diminish considerably the quantity of soluble matter which it contains. We shall here insert the table drawn up by Mr Combrune, from his own experiments, of the colour of malt dried in different temperatures.

Heat.	
119°	White.
124	Cream-colour.
129	Light yellow.
134	Amber-colour.
138	High amber.
143	Pale brown.
148	Brown.
152	High brown.
157	Brown inclining to black.
162	High brown speckled with black.
167	Blackish brown with black specks.
171	Colour of burnt coffee.
176	Black.

We have given this table, not on account of any information which it contains, but to put our readers on their guard against the false conclusions of this writer. We have taken malt dried at the temperature of 175°, put it into a garden pot filled with soil, and have seen it vegetate apparently as well as raw grain placed in the same situation. Now, this is only one degree lower than that in which Mr Combrune says malt is converted into charcoal, and it is four degrees higher than that in which his malt assumed the colour of burnt coffee. Certainly malt reduced to the colour of burnt coffee by heat would be deprived of the power of vegetating. Mr Combrune's experiments were made by putting malt into an earthen pan, which he placed over a charcoal fire in a stove, while he kept stirring the malt the whole time of the experiment. The bulb of the thermometer was placed half-way between the upper surface of the malt and the bottom of the vessel. Now the reader will perceive at once that the earthen pan would be much hotter than that part of the malt where the thermometer was placed. By the con-

stant stirring of the malt, the whole of it was gradually exposed to the burning action of the surface of the pan. Had the experiment been made without stirring the malt at all, and had the thermometer been placed near the surface, in that case the changes in the colour of the malt at the surface would have indicated the temperature to which it was exposed. But in the way that Mr Combrune conducted his experiments, the temperatures which he obtained were entirely fallacious. We have not the least doubt that the temperature of the earthen pan, towards the end of his experiment, was above 400°.

Mr Combrune's law, however, that the heat of the water in mashing ought to be regulated by the colour of the malt; namely, that the paler the malt is, the lower ought the temperature of the mashing water to be, is founded on accurate observations. The fact is, that boiling water would answer better than any other for mashing, because it would dissolve most speedily the soluble part of the malt. The only reason for not using it is, that the tendency of the malt to *set* increases with the temperature of the water. Now the higher the colour of the malt, the less is its tendency to set; but we may nevertheless use water of a higher temperature to mash with it. For the same reason, when raw grain is used, the temperature of the mashing water must be still lower than when malt is employed; because raw grain has a very great tendency to set.

The old malt-kilns had a bottom of hair-cloth instead of the iron plates full of holes, which constitute a more recent improvement. We have seen the thermometer in such a kiln, when the bulb touched the hair-cloth, rise as high as 186°. In general, the temperature of the malt-kiln is very carelessly regulated. We have seen malt for the very same purpose dried at a temperature which never rose higher than 136°; while a portion of the very same malt, put into another kiln, was heated as high as 186°. But such a careless mode of drying malt is reprehensible, and must be more or less injurious to the brewer. In general, the more rapidly malt is dried the more does its bulk increase. This method, accordingly, is practised by those who malt for sale, as is the case with most of the English maltsters; because malt is always sold by measure, and not by weight. The brewers would find it more for their interest to buy malt by weight than by measure. In that case the maltsters would dry their malt at as low a temperature as possible. But this would signify very little, or rather would be advantageous to the brewer; because dried malt soon recovers the moisture lost on the kiln when kept for some time in sacks. And when malt is dried at a low temperature, we are sure that none of it is injured by the fire. It will, therefore, go farther in the production of beer. The time of kiln-drying varies considerably, according to the quantity of malt exposed to the action of the heat; but when that quantity is not too great, we may estimate the time of kiln-drying, in general, at two days. After the fire is withdrawn, the malt is allowed to remain on the kiln till it has become nearly cold.

By the kiln-drying, the roots of the barley, or, as the maltsters call them, the *comings*, are dried up and fall off. They are separated from the malt by passing it over the surface of a kind of wire screen, which allows the *comings* to drop through, while the wires are too near each other to permit the grains of malt to pass.

If 100 lbs. of barley malted in this manner, with all the requisite care, be weighed just after being kiln-dried and produced clean, they will be found, on an average, to weigh 80 lbs. But if the raw grain be kiln-dried at the same temperature as the malt, it will lose 12 per cent. of its weight. Hence 12 per cent. of the loss which barley sustains in malting must be ascribed to moisture dissipated by the kiln-drying; so that the real loss of weight which barley

loss is owing to the formation and escape of carbonic acid gas. Brewing.

Big sustains a considerably greater loss of weight when malted than barley. The average loss of weight in our trials with barley was only eight per cent., while that of big was fifteen per cent., or nearly double. This, we conceive, is owing to the destruction of a much greater number of the corns during the process of malting big than barley. But in all our experiments on big, that grain was manifestly oversteeped. To this, perhaps, a good deal of the difference may be ascribed. Our maltsters had not been in the habit of malting big, and therefore were not likely to do it so much justice as they did to the barley. Hence it would be improper to venture upon any general conclusions from the experiments which we made upon the malting of big.

The bulk of the malt is usually greater than that of the barley from which it was obtained ; but this varies a good deal according to the goodness of the grain and the mode of drying the malt. In our trials, made all in the same way, 100 bushels of the different kinds of grain gave, on an average, the following results :

The greatest quantity in bushels obtained from 100 bushels of English barley was $111\frac{1}{4}$, the least 106 bushels. The greatest quantity obtained from 100 bushels of Scotch barley was 109, and the least 98 bushels. The greatest quantity obtained from 100 bushels of big was 103 bushels, the least 97 bushels. Hence it appears that, on malting English barley, there is a profit of nine per cent., while big yields scarcely any thing more than its bulk before malting. The English maltster makes more bushels of malt than he pays duty for; but the maltster of big, on the contrary, obtains fewer.

We shall subjoin here two tables, which exhibit in one view the result of a considerable number of trials made by the author of this article, on malting different varieties of grain. The barley is distinguished by the name of the county where it grew. To understand the first table, the reader must know that excisemen estimate the quantity of malt by subtracting one fifth from the best or highest gauge in the steep or couch, and charge the duty accordingly.

Brewing.
Nature of
the pro-
cess.

Thus it appears that the process of malting is nothing else than causing the barleycorns to germinate, and stopping that process before the green leaf makes its appearance. A quantity of roots are formed, which are afterwards rubbed off and separated, and the weight of which amounts to about four per cent. of the grain malted. The kernel of the grain undergoes a remarkable change by this process. It consists almost entirely of starch; but it was agglutinated in the grain, so as to form a solid and very firm mass; whereas, in the malt, it is quite loose and mealy. Hence it would appear that the glutinous and mucilaginous matter of the barleycorn is chiefly employed in forming the roots; and that this is the purpose for which it was laid up in the grain. How far the starch is altered does not appear. It is probable that it has undergone some change. Malt has a slightly sweet taste, much more agreeable than the taste of the raw grain, without any of that strong and cloying sweetness which distinguishes wort. But the most distinguishing character of the starch of malt is the ease with which it dissolves in hot water; though cold water does not act upon it sensibly. Whether this property be peculiar to the starch of barley, or be induced by the malting, we cannot say. We conceive it probable that barley starch is more easily soluble in water than wheat starch, from the ease with which raw grain is constantly employed by distillers to form their worts. In its other chemical characters, the starch of barley malt agrees with that of wheat starch.

Soluble
part of
malt.

We should err very much, however, were we to suppose that the whole kernel or starchy part of the malt is dissolved by the hot water used in brewing. At least one half of the malt still remains after the brewing is over, constituting the grains, which are known to constitute a most nourishing article of food for cattle, and therefore to contain much more than the husks or skin of the malt corn. One hundred lbs. of malt from different kinds of grain, after being exhausted as much as usual of the soluble part of the kernel by hot water, were found to weigh as follows:—

English barley.....	50.63 lbs.
Scotch barley.....	50.78
Scotch big.....	52.69

100 lbs. of raw grain being converted into malt, and the soluble part of the malt extracted by hot water, the residue weighed,—

English barley.....	51.558 lbs.
Scotch barley.....	50.831
Scotch big.....	53.500

In another set of experiments, 100 lbs. of malt left the following residues:—

English barley.....	54.9 lbs.
Scotch barley.....	56.9
Scotch big.....	56.6

100 lbs. of the raw grain being converted into malt, and the soluble part of the malt extracted by hot water, the residues weighed,—

English barley.....	54.8 lbs.
Scotch barley.....	56.9
Scotch big.....	56.6

Hence we see that in all these cases the bulk of the malt was very nearly the same as the previous bulk of the barley before it was malted.

In another set of experiments, 100 lbs. of malt left the following residues:—

English barley.....	54.0 lbs.
Scotch barley.....	56.1
Scotch big.....	56.6

100 lbs. of the raw grain being converted into malt, and the soluble part of the malt being extracted by hot water, the residues weighed,—

English barley.....	54.63 lbs.
Scotch barley.....	56.09
Scotch big.....	56.59

Brewing

Here also the bulk of the malt differed but little from that of the raw grain. The first of these sets of experiments was made with grain of the best quality, the second with grain of the middling quality, and the third with grain of the third quality.

It is probable that an additional portion of the kernel would be dissolved if the malt were ground finer than it is customary to do. The reason for grinding it only coarsely is to render it less apt to set. But this object might be accomplished equally well by bruising the malt between rollers, which would reduce the starchy part to powder, without destroying the husk. This method, indeed, is practised by many brewers, but it ought to be followed by all.

CHAP. IV.

OF BREWING.

Brewing consists of five successive processes, which are distinguished by the following names: 1. *Mashing*; 2. *Boiling*; 3. *Cooling*; 4. *Fermenting*; 5. *Cleansing*. We shall afterwards give a description and view of the utensils employed in a large London porter brewery, where they have been carried to the greatest perfection. But we conceive it better to give a description of the processes themselves, in the first place, without referring them to any specific form of vessels; observing only, that the size of all the utensils must be proportional to the quantity of beer which it is proposed to make at once.

1. The specific gravity of malt varies a good deal, according to the way in which it is dried upon the kiln; but its mean specific gravity may be stated at 1.201. In general the specific gravity of big malt is rather inferior to that of malt from barley. Let us suppose, for the sake of stating the comparative quantities, that it is our object to employ in a single brewing fifty bushels of malt. The first thing to be done is to grind the malt in a mill, and the best kind of mill for the purpose is that in which the malt is made to pass between two iron rollers.

We must be provided with a copper boiler capable of containing at least the fifty bushels of malt; or its solid contents must, at the smallest, amount to 382 ale gallons, which are rather more than 107,521 cubic inches or 62½ cubic feet. This copper boiler must be placed over brick work upon a furnace, and there must be conveniences for filling it with water, and for letting the water off when sufficiently heated, into the mash-tun.

The mash-tun is a wooden vessel composed of staves properly fixed by means of iron hoops, and usually placed in the middle of the brew-house. It has a false bottom full of holes at some little height above the true bottom. Its capacity varies according to the extent of the brewery establishment; but a mash-tun capable of mashing fifty bushels of malt must be at least one third larger than the bulk of the malt, or it must be capable at least of containing 75 bushels.

A quantity of water, equal at least in bulk to that of the malt, is to be put into the boiler, and heated up to 190° or 180°, according to the fancy of the brewer and the quality of the malt; but the best brewers, in general, employ the lowest temperature. This water is then to be let into the mash-tun, and the malt, previously ground, is to be let down into it immediately after. It is then mixed with the water and all the clots carefully broken, either by workmen, who use for the purpose very narrow wooden shovels, or, when the capacity of the mash-tun is very great, as in the London breweries, by a machine which is

driven by a steam-engine. Great care must be taken to break all the clots, because the whole of the malt within them would otherwise escape the action of the water, and be lost to the brewer. When the water and malt are sufficiently mixed, the mash-tun is covered and left in this state about three hours. But the time varies according to circumstances.

Though the specific gravity of a malt corn be greater than that of water, yet if it be thrown into that liquid it always swims. The reason is, that between the skin and the kernel there is lodged a quantity of air, which it is not easy to drive away. Accordingly, brewers are in the habit of judging of the goodness of malt by throwing a certain quantity of it into water, and, reckoning the grains which fall to the bottom, these indicate the proportion of unmalted grain which the malt contains. Of course the more of them that exist in any given quantity of malt, the worse must the malt be considered. But though malt, when we consider only single corns, is about a sixth heavier than water, yet a bushel of malt does not weigh so much as one third of a bushel of water. For, on one occasion, the hot water in the mash-tun, before the addition of the malt, stood at the height of twenty-two inches. On adding the malt, it rose to the height of twenty-nine inches. The bulk of the water was fifty-one bushels; that of the malt before grinding, forty-seven and a half bushels. We see from this that the real space occupied in the mash-tun by the forty seven and a half bushels of malt was only seven inches, while the fifty-one bushels of water occupied the space of twenty-two inches; therefore about two thirds of the bulk of the unground malt consisted of interstices filled with air.

The temperature of the water is considerably lowered when it is mixed with the malt, but we have been unable to determine how much, from the impossibility of thrusting a thermometer down to the centre of the mash-tun, the only place that would give a correct result. But we may state a few out of the many observations which we have made on the subject; fifty-one bushels of water of the temperature 192° were mixed with forty-seven and a fourth bushels of malt; after mixture, the temperature at the surface of the mash was 140°. Two hours and a half after, when the wort began to run off, its temperature was 156°, and at that time the surface of the mash was at the temperature of 136°. If we suppose in this case that the whole mash lost four degrees as well as the surface, and take the mean between the bottom and top, we shall have the mean heat of the whole, after the mashing, 150°; so that the water has lost 32° of heat, while the malt (its temperature before mixture was 48°) gained 102°.

The weight of the water, reckoning it at 51 bushels, was.....3965.25 lbs.
That of the malt was.....1788.80 lbs.

This would make the specific heat of the malt 0.69, which is probably considerably above the truth; for, according to the experiments of Dr Crawford, the specific heat of barley is only 0.421; so that our supposition, that the mean temperature after mashing was only 150°, is not quite accurate. Were we to suppose the specific heat of malt to be 0.42, which cannot be very far from the truth, in that case the mean temperature, after mashing, would be 169°, if the water was 192° and the malt 48°, and the weight of each as above stated.

In another experiment, in which sixty bushels of malt were mashed, the heat of the water was 180°, that of the malt 56°, the temperature, on adding the malt to the water and mixing it well, was at the surface 141°. Four hours after, when the wort began to be drawn off, its temperature was 150°, and that of the surface of the mixture of malt and water in the mash-tun was 138°.

VOL. V.

The bulk of water was 66½ bushels, its weight 5157 lbs. The weight of the malt was.....2283.6 lbs.

Any person may easily, from these data, calculate what the heat of the mixture after mashing ought to be, supposing the specific heat of the malt to be 0.42. The common formula for the calculation is

$$S = \frac{W \times w - m}{B \times m - b},$$

in which S denotes the specific heat of the malt, W the weight of water used, w its temperature, B the weight of malt used, and b its temperature, and m (which in the present case is the quantity sought) the temperature after mixture. We do not think it worth while to give any more examples of these changes of temperature, though we are in possession of abundance of them; because we do not conceive that they can lead to any useful results.

After the mash has continued for about three hours (or Wort longer or shorter according to circumstances), a stop-cock, placed below the false bottom in the mash-tun, is opened, and the wort allowed to run out into a vessel prepared to receive it, and known by the name of *underback*. At the same time the cover is taken off the mash-tun, and quantities of water of the temperature of 180° are occasionally sprinkled over it from the boiler, which had been again filled with water to be heated as soon as the water for mashing was drawn off. No specific directions can be given respecting the quantity of hot water added in this manner by sprinkling, because that must depend upon the views of the brewer. If he wishes to have ale of very great strength, he will of course add less water; if the ale is to be weak he will add more. The best way is to determine the strength of the liquor as it flows into the underback, by means of a saccharometer, or by taking its specific gravity. When the specific gravity (at 60°) sinks to 1.04 or 1.05, or when it contains only 36½ or 46½ lbs. per barrel of solid matter in solution, it would be useless or injurious to draw any more off for making strong ale. But an additional portion may still be drawn off and converted into small beer. We have seen the brewers in Edinburgh continue to draw off small beer from the mash-tun till the liquid indicated only 23½ lbs. per barrel, or even till it indicated 17½ lbs. per barrel; that is, till its specific gravity at 60° was reduced to 1.027 or 1.020. Indeed the strength of small beer is often much weaker than this when it is obtained from malt without drawing off any strong ale wort; but when it is the residue of strong ale, it is necessary to make it stronger, otherwise its quality will be bad. About twenty-five years ago, it was customary with some of the small-beer brewers in Edinburgh to make the small beer of considerable strength; and after the exciseman had determined its quantity, and the duty to be paid on it, they diluted it largely with water, just when they were sending it out of the house. This fraud was easily put in practice, because the small beer is usually disposed of the moment it is mixed with the yeast, and before it has undergone any fermentation whatever. It ferments sufficiently in the small casks in which it is sent to the consumers. In Edinburgh it is customary to bottle this small beer, which makes it clear and very brisk, and consequently very agreeable to the palate.

Neither can any general rule be laid down for the specific gravity or strength of the wort when it begins to flow from the mash. It will obviously depend upon the goodness of the malt, and upon the quantity of mashing water employed, when compared with the quantity of malt. We have seen it begin to flow from the mash-tun of the specific gravity 1.084, 1.0805, 1.0815, 1.0835, 1.091, 1.094, or containing respectively 78½, 74½, 75½, 78, 85, and 87½ lbs. per barrel.

The wort, as it first flows from the mash-tun, is a trans-

Brewing. parent liquid of a fine amber colour, a peculiar smell, and a rich, luscious, sweet taste. If it is cloudy, as sometimes happens, it is a proof that the water used for mashing was of too high a temperature. We have seen the wort run cloudy from the mash-tun when the temperature of the water had been as high as 200° or 191°, but never when it was no higher than 180°. This affords an additional reason with the brewers for keeping the temperature of the mashing-water low. But we have some doubts about the accuracy of the reason. For, when the wort is afterwards boiled, it always deposits a copious flocky sediment. The boiling would doubtless render even turbid wort transparent, and would not probably increase the sediment much. At the same time it must be acknowledged, that some obscurity hangs upon this part of the process of brewing. For we have seen wort continue opaque during the whole process of boiling, cooling, and fermenting, and requiring ultimately to be clarified, or *fined*, as the brewers termed it, by means of isinglass. The substance which rendered the ale in this case turbid seemed to be a variety of starch, or some particular form of that substance, for it was completely precipitated by infusion of nutgalls, and the precipitate was redissolved by the application of a moderate heat.

The flowing of the wort from the mash-tun takes up six or eight hours. As it advances the colour diminishes, the smell becomes less agreeable, and the taste less sweet. At last the colour becomes nearly opal, and the smell becomes sour, and somewhat similar to the odour emitted by an infusion of meal and water left till it has become sour. Yet it produces no change on vegetable blue colours.

Constitu-
ents of
wort.

If the wort which first comes over be evaporated to dryness, it leaves behind it a yellow-coloured residuum, which has a sweet taste, dissolves readily in water, absorbs water from the atmosphere, and becomes clammy, and similar in appearance to treacle. Its specific gravity is 1.552. This does not differ much from the specific gravity of common refined sugar, if we take a mean of the experiments of Fahrenheit and Hassenfratz. Fahrenheit found the specific gravity of sugar 1.6065, while Hassenfratz found it 1.4045, the mean of which is 1.5055. There can be no doubt that this residue contains a good deal of sugar, precisely the same in its properties with the sugar into which starch is converted by boiling it in a very dilute acid. But it is mixed likewise with a considerable portion of starch, which has become soluble in water, without being converted into sugar. For wort gives a copious precipitate with the infusion of nutgalls, and this precipitate is redissolved by a moderate increase of temperature, properties which characterize starch.

From the experiments of Saussure, it would appear that starch sugar is nothing else than a combination of starch and sugar. Hence it is probable that, during the mashing, a combination takes place between the starch of the malt and the water, the result of which is the formation of starch sugar. This sugar agrees in its properties with the sugar of grapes. It crystallizes in needles grouped together in the form of small sapericles like granulated honey. It does not go so far in sweetening as common sugar, and, like sugar of grapes, it ferments without the addition of yeast. We have attempted in vain to separate the saccharine part of the residue of wort from the starch. When alcohol is poured over it, no solution takes place; but such is the affinity of the residue of wort for water, that it deprives the alcohol of a portion of its water, just as carbonate of potash or muriate of lime does, and a very viscid liquid, consisting of the residue of malt dissolved in a very small quantity of water, is formed at the bottom of the vessel.

It is exceedingly difficult to evaporate wort without

partly decomposing the extractive residue. The best way is to put it upon a very flat dish, and to apply a heat not greater than 120°. We have charred it completely in a glass vessel, filled with alcohol, without applying heat sufficient to make the alcohol boil. Indeed we never succeeded in obtaining the residue of wort without its colour being a good deal darker than that of the wort from which it was obtained.

The wort which runs off last contains very little saccharine matter; but some starch and mucilaginous matter may still be detected in it. The flavour and beauty of the ale is increased if we take only the wort that runs first off, and throw away the last drawn worts, or employ them only in the manufacture of small beer.

2. The next process in brewing is the *boiling* of the wort. The wort is pumped up from the *underback* into the copper boiler, where it is boiled for several hours, till it has acquired the degree of strength which is wanted by the brewer.

It may be proper to give some examples of quantities, to enable the reader to form a better idea of the effect of the boiling.

From sixty bushels of malt there were obtained 23.465 barrels of wort, of the strength of 64.37 lbs. per barrel, or of the specific gravity 1.0683. It was boiled down to 19.736 barrels of the strength of 82.7 lbs. per barrel, or of the specific gravity 1.089.

From sixty bushels of big malt there were obtained 23.8193 barrels of the specific gravity 1.0648, or of 58.75 lbs. per barrel of saccharine matter. It was boiled down to 19.736 barrels of the specific gravity 1.078, or of 72½ lbs. per barrel of saccharine matter.

From seventy-two bushels of malt 15.1388 barrels of the specific gravity 1.071, or of 60.6 lbs. per barrel, it was boiled down to 13½ barrels of the specific gravity 1.1055, or of 98½ lbs. per barrel of saccharine matter.

From fifty bushels of malt 13.444 barrels of wort were obtained, of the specific gravity 1.068, or of 63.125 lbs. of saccharine matter per barrel. It was boiled down to 11.083 barrels of the specific gravity 1.1015, or of 94½ lbs. per barrel.

Various contrivances have been fallen upon to economize the boiling process; but these will come under our consideration with more propriety when we proceed to give an account of the utensils in a London brewery.

The flocky precipitate which forms during the boiling of the wort, as far as we have been able to determine its properties, approaches nearly to the nature of gluten or vegetable albumen, for these two substances differ very little from each other.

While the wort is in the boiler, the requisite quantity of hops are added to flavour the ale, and render it capable of being kept for a considerable length of time without souring. Hops, as is well known, are the seed-pods of the *Humulus lupulus* or *hop-plant*, which is cultivated in considerable quantities in the south of England, especially in Kent and Hampshire. The seed-pods of this creeping plant are collected when ripe, and dried upon a kiln. They are then packed up in bags, and sold to the brewers. Hops are well known to have a peculiar bitter taste, and a weak aromatic odour, and to possess sedative qualities to a considerable extent. A pillow filled with hops has often been found to induce sleep when every thing else has failed. If they be digested for some days in alcohol, that liquid acquires a slight greenish colour, a peculiar taste, and an odour in which that of the hop can be distinctly perceived. If the alcohol, previously freed from the undissolved matter, be distilled in a retort, there remains behind a solid green-coloured oil. It is to this oil that hops owe their peculiar smell. Its taste is peculiar,

wing. sharp, and scarcely bitter, but putting one in mind of the peculiar flavour of good ale. This oil is the part of the hops which gives ale its distinguishing flavour. It is apt to be dissipated by long boiling. Hence, when hops are too long boiled in wort, the aromatic odour and peculiar flavour are nearly dissipated, and a bitter taste substituted. It is the opinion of brewers, that the intoxicating qualities of ale are to be partly ascribed to the oil of the hop. Indeed it has been pretty common to ascribe intoxicating qualities to bitter-tasted substances in general. Thus, a woman of the name of Johnston, who kept a public-house a little to the south side of the Meadows, near Edinburgh, about the beginning of the last century, was famous for brewing a pleasant and very intoxicating ale; and the last quality was universally ascribed to the broom tops which she employed as a bitter instead of hops. This woman's name is remembered, because her ale and her house are celebrated in the poems of Allan Ramsay. But the opinion above stated, though very general, does not appear to be founded upon any precise experiments or observations. We are not acquainted with any volatile oil which produces intoxication; though some of them, as oil of turpentine, act with great energy upon the stomach. No infusion of any bitter whatever, not even of hops, is known to produce intoxication; nor is any effect in the least similar to intoxication produced when considerable quantities (2 oz. per day for example) of Peruvian bark are swallowed in substance.

Besides the volatile oil, hops contain likewise a quantity of bitter principle, which may be easily extracted from them by water. As far as we were able to determine the point, this bitter matter possesses the characters of the bitter principle in perfection. No re-agent that we tried is capable of throwing it down except acetate of lead, a somewhat ambiguous precipitant, because it throws down the greater number of vegetable substances, and because the lead in this salt is partially thrown down by carbonic acid, if it happens to be present in the solution. Nitrate of silver is likewise a precipitant, throwing down the bitter principle of hops in light yellow flocks. But this precipitant is also somewhat ambiguous, for the same reason that renders acetate of lead so. The bitter principle of hops is likewise very soluble, both in water and in alcohol.

Hops communicate both their flavour and their bitter taste to wort. The quantity employed varies very much, according to the taste of the persons who are to drink the ale. The stronger the ale, the greater is the quantity of hops which it can bear without injury. In general, English brewers employ a much greater quantity of hops than the Scotch brewers. To elucidate the subject, we shall give a few examples of the quantity of hops used in making Edinburgh ale; which is known to be mild, and, in general, is much relished by most of those who are in the habit of drinking ale.

Sixty bushels of malt yielded 11.75 barrels of strong ale wort, measured at the end of the boiling, and 40 pounds of hops had been mixed with it in the boiler.

Forty-seven and a quarter bushels of malt furnished 10.83 barrels of wort, measured after being boiled and cooled, and 36 lbs. of hops had been mixed with it in the boiler.

Sixty bushels of malt furnished fifteen barrels of wort, measured after boiling and cooling, and 45 lbs. of hops had been mixed with it in the boiler.

Sixty bushels of malt, from big, furnished 14.7 barrels of wort, after being boiled and cooled. It was mixed with 40 lbs. of hops in the boiler.

In another brewing in which 72 bushels of malt, from big, furnished 10½ barrels of wort, 66 lbs. of hops had been added in the boiler.

In general, when the ale has considerable strength, the

Edinburgh brewers are in the habit of adding one pound of hops for every bushel of malt employed. Sometimes, indeed, when they wish their ale to be very superior in flavour and quality, they employ a greater quantity of hops than even this. Thus we have seen 100 lbs. of hops boiled in the strong ale wort extracted from 72 bushels of malt. When the ale is but weak, and consequently cheap, the usual allowance is one pound of hops to a bushel and a half of the malt.

3. After the wort has been boiled down to the requisite strength, which, in Edinburgh, is commonly between the specific gravities 1.09 and 1.10, it is let out into the coolers. The coolers are floors of wood, surrounded with a wooden ledge, and water-tight, placed in the most airy and exposed situation in the brewery. They are of such a size as to hold the whole of the wort at a depth not exceeding three or four inches; so that, in large breweries, they are of an enormous extent. The object is to cool down the wort as rapidly as possible to the temperature of the atmosphere; because, if it were allowed to remain long hot it would run the risk of becoming sour, which would spoil the whole process. A great deal of the superiority of some breweries over others depends upon the construction of the coolers, or rather, upon their being as well adapted as possible for reducing the temperature of the wort speedily to that of the atmosphere. A free current of air ought to pass over them, and great care should be taken to keep them perfectly clean.

The wort is either pumped out of the boiler into the coolers, or it is let into them by simply opening a stop-cock, according to the construction of the brew-house. It soon spreads itself over all the surface of the coolers, and a very great evaporation is the consequence. This evaporation ought always to be taken into consideration by the brewer; because it both materially adds to the strength of the ale and diminishes its quantity. The amount of it depends upon the temperature of the air compared with that of the atmosphere, and upon the skill with which the coolers have been constructed. We shall give a few examples of the quantity of evaporation which took place during the cooling of worts, in coolers by no means remarkable for the goodness of their construction.

Temperature of the Wort when let into the Coolers.	Temperature of ditto when cold.	Quantity of Wort when let into the Coolers in Ale Barrels.	Ditto when cooled.	Quantity evaporated in Ale Barrels.	Time of Cooling, in hours.
160°	56°	16.1388	14.8611	1.2777	11½
176	51	18.6666	17.2222	1.4444	11½

Brewing.

In the first two examples in the above table, the quantity of wort was estimated just when it was let down into the coolers; in all the others it was estimated in the boiler before it was pumped out. It appears from the preceding table that rather more than one fourth of the whole wort is dissipated by evaporation during the cooling; and, if we had excepted from the general consideration the first two examples, the proportion evaporated would have been still greater.

When the wort is let out of the boiler into the cooler, the hops still remain, and, as they are soaked with wort, a considerable loss would be sustained if they were thrown away. Thus we found, in one instance, that 45 lbs. of hops retained half a barrel of wort after they were drained so completely that no more wort would drop out. In another case, 35 lbs. of hops retained in the same way 0.3666 of a barrel, which is rather more than one third of a barrel. To recover this wort it is proper to subject the hops to pressure. We do not know whether this is attended to by the great brewers, though it probably is. By several of the Edinburgh brewers it is, we believe, too much neglected.

In cold weather, where the brewery is small, and the apartment in which the fermenting vessels are placed, cold, it is proper not to reduce the temperature of the wort as low as that of the atmosphere. From want of attention to this circumstance, we have seen wort refuse to ferment for some time, and the brewer under the necessity of heating it artificially before fermentation could be brought on. In such cases the wort is very apt to be lost altogether by contracting acidity. The temperature, in such cases, ought not to be reduced lower than 56°. But when the apartment in which fermentation is carried on is warm, 51° or 52° is a very good temperature. When the brewer is obliged to make ale in warm summer weather, it is material to reduce the temperature as low as possible. In such cases great advantage would attend cooling the wort in coolers without any roof or covering whatever, but quite open to the sky; because, in clear nights, the wort might be cooled in this way, eight or ten degrees lower than the temperature of the atmosphere. The reason is obvious. It is owing to the rays of heat, which, in such a case, radiate from the wort, and are not returned again by the clear sky. Wort, being a good radiator of heat, would be particularly benefited by this method of cooling. We have no doubt that it might be put in practice with advantage in hot climates; and that, by means of it, good ale or porter might be manufactured in the East and West Indies. Such a manufacture, if successful, would be particularly relished in India, and would, we doubt not, prove a lucrative article of manufacture to an enterprising man.

While a duty was levied on ale and beer according to their quantity, excisemen were in the habit of gauging the wort while in the boiler and when on the coolers. Not that the duty was levied according to the quantities there found, but to serve as a check upon the more accurate gauges taken in the fermenting tuns. For a certain allowance being made for evaporation while the wort is in the cooler, which the excisemen, from long observation, are enabled to do with some accuracy, they have it in their power, from these checks, to determine whether any of the wort from the coolers has been secreted or carried off with a view to evade the excise laws. In the year 1830 the duty on beer was taken off. The consequence of this is, that the brewer is now entirely freed from the exciseman, and at liberty to improve his processes at pleasure. We doubt not that in a short time this will be followed by considerable improvements in *brewing*.

4. When the wort is sufficiently cooled down by expo-

sure on the coolers, it is let down into the fermenting-tuns, or, as the brewers call them, the gyle-tuns, in order to be fermented; by which process it is converted from the luscious sweet-tasted liquor called *wort*, to the brisk intoxicating liquor which constitutes *ale*. The gyle-tuns are cylindrical wooden vessels, varying in size according to the extent of the brewery. In the London breweries, and in the distilleries, they are of prodigious size; but in private houses they often do not exceed the size of a wine hogshead, or even of a beer barrel. The fermentation is perhaps conducted with the greatest economy in large vessels; but good ale may be made in comparatively small quantities. How far this is the case with porter, it is more difficult to say. Good porter has scarcely ever been made, except by those who manufacture it upon a large scale.

The fermenting tuns are not to be filled by the wort, because a considerable increase in bulk takes place during the fermentation, in consequence of which the liquor would run over, unless allowance were made for it.

The fermentation of ale or beer is never carried to any great length. The object of the brewer is, to retain the flavour and good qualities of the ale or beer, not to develop the greatest quantity of spirits, which can hardly be done without allowing the wort to run into acidity. The violence of the fermentation depends upon the quantity of yeast added. Brewers, accordingly, mix yeast with their worts only in very sparing quantities, while the distiller adds it in great doses, and repeatedly.

Yeast is a frothy substance, of a brownish-grey colour and bitter taste, which is formed on the surface of ale or wine while fermenting. If it be put into sacks the moisture gradually drops out, and the yeast remains behind in a solid form. It has very much of the flavour and taste of cheese when in this state; but its colour is still darker. This dried yeast promotes or excites fermentation, but it does not answer quite so well as fresh yeast. At one period some of the Scotch distillers employed considerable quantities of it; but all of them with whom we conversed on the subject affirmed that it was much less profitable than even the bad porter yeast which they were in the habit of bringing down from London. From the resemblance which dried yeast has to cheese, one would be disposed to infer that it is a species or variety of gluten. But if we attempt to induce fermentation in wort by adding the gluten of wheat, we will be unsuccessful.

When yeast is kept for some time in cylindrical glass vessels, a white substance, not unlike curd, separates and swims on the surface. If this substance be removed, the yeast loses the property of exciting fermentation. This white substance possesses many of the properties of gluten, though it differs from it in others. Its colour is much whiter, it has not the same elasticity, and its particles do not adhere with the same force. In short, it agrees much more nearly, in its properties, with the curd of milk than with the gluten of wheat. We are disposed to consider this substance as the true fermenting principle in yeast, though we were never able to procure a sufficient quantity of it to put its fermenting powers to the test of experiment. We have sometimes seen a similar substance separate in the fermenting tuns in distilleries, when the fermentation was nearly at an end; or, rather, when such a quantity of spirit had been generated as put an end to the fermenting process altogether. But we could never learn that the distillers had formed any opinion respecting this curdy substance. It did not interfere with the success of their operations, and, on that account, they bestowed little attention on it. We attempted, once or twice, to collect such a quantity of it as might enable us to try its powers as a ferment, but we did not succeed.

The only chemist who has attempted to subject yeast to a chemical analysis is Westrumb; but, though this philosopher was distinguished for his accuracy, the task was too difficult for the resources of the science of the time (1796) when he published his *Experiments*. From 15,360 parts of fresh beer yeast he obtained the following substances:—

Potash.....	13
Carbonic acid.....	15
Acetic acid.....	10
Malic acid.....	45
Lime.....	69
Alcohol.....	240
Extractive.....	120
Mucilage.....	240
Saccharine matter.....	315
Gluten.....	480
Water.....	13,595
	15,142
Loss.....	218
Total.....	15,360

As yeast may be reduced to a dried state without depriving it of the power of acting as a ferment, it is clear that the carbonic acid, acetic acid, alcohol, and water, are not essential to it. We cannot suppose that either potash, lime, or malic acid, is essential. The saccharine matter, we know, is capable of fermenting of itself; but if it were the essential ingredient, it would be quite unnecessary to add yeast to wort at all, as we know that the wort contains abundance of saccharine matter in solution. We know likewise, from experiment, that neither extractive, mucilage, nor gluten, possesses the property of exciting fermentation. Thus none of the substances found by Westrumb in yeast can be considered as the true fermenting principle. Dobereiner found, that when yeast is steeped in alcohol, it loses the property of acting as a ferment. This may be owing to the alcohol dissolving and carrying off the true fermenting principle. But we are rather disposed to ascribe it to the presence of a portion of alcohol in the yeast. We know that a certain portion of alcohol destroys fermentation. Thus we have found, by a great many trials, conducted on rather a large scale, that the stronger a wort is made, the greater is the quantity of unaltered saccharine matter which remains in it after the fermentation has been carried to the greatest possible length. Hence the present mode of levying the duties on spirits upon the wash is not only very injurious to the goodness of the spirits manufactured, but is attended with a positive and very heavy loss to the community. Distiller's wash may be fermented a second time, and would in this way yield a considerable additional quantity of spirits. We have frequently seen it made into good small beer. The proper mode of levying the duty would be on the quantity of saccharine matter in the wash. This might easily be determined by a good saccharometer. A certain part of the duty might likewise be levied upon the spirits produced. This would act as a sort of check upon the first estimate, and would considerably diminish the risk of fraud. Indeed, the mode of determining the duty by the quantity of saccharine matter would not be more liable to evasion than the present mode. It could be evaded in no other way than by concealing a portion of the wash, which would be equally efficacious according to the present mode.

We conceive, therefore, that when yeast is mixed with alcohol, it may retain so much of that liquor as to prevent it from acting as a ferment. When we attempt to wash away the alcohol, we may destroy the yeast by washing

away that portion of it which really acts as a ferment, which is probably small in quantity.

It seems to us not unlikely, that the portion of yeast which really acts as a ferment is a quantity of saccharine matter which it contains, that has begun to undergo the decomposition produced by fermentation, but has not yet completed the change. For nothing more seems to be necessary than to begin the fermentative process in wort; the process then goes on of itself. It would be curious to know whether a high temperature (96° or 100°) might be substituted in distilleries for the great quantities of yeast at present employed. We believe that the reason why such great quantities of yeast are necessary in distilleries, is the very great strength of the wash employed; as they are obliged by law to produce a quantity of proof spirits amounting nearly to one fifth of the whole bulk of the wash. Nothing can be more preposterous than such a method, nor more contrary to the real interest of the community, which obviously must be to produce the greatest quantity of good spirits from a given quantity of grain.

The quantity of yeast mixed with the wort in the fermenting tuns by brewers is very small, amounting, at an average, to a gallon of yeast for every three barrels of wort. The following table will give the reader an idea of the quantities of yeast really mixed by the Edinburgh brewers with their strong ale worts in different brewings. It is obvious, however, that the quantity of yeast must be regulated in some measure by its goodness.

Quantity of Wort in Barrels.	Specific Gravity.	Lbs. per Barrel of Saccharine Matter.	Quantity of Yeast added in Gallons.
10-611	1-106	99	3-5
10-83	1-104	97 $\frac{1}{4}$	4
14-944	1-096	89 $\frac{1}{2}$	2-5
14-8055	1-093	86 $\frac{3}{4}$	3-75
14-6388	1-093	86 $\frac{3}{4}$	2-83
14-722	1-082	76 $\frac{1}{2}$	2-83
10-201	1-091	86 $\frac{1}{4}$	1
9-75	1-091	86 $\frac{1}{4}$	1
11-478	1-098	91 $\frac{1}{2}$	1
9-25	1-096	89-67	1

The last four brewings, in which the quantity of yeast added was smaller than in the first six, took place during the month of May, when the heat is apt to make the fermentation run to excess. The variation in the quantity, so conspicuous in the first six brewings, is partly to be ascribed to differences in the goodness of the yeast, but chiefly to the carelessness and want of method which distinguished the brewer in question beyond any one we ever met. But we have taken his quantities to show that differences in the quantity of yeast are not material; for all the preceding brewings, except the first, furnished very good ale. The wort in the first brewing had been cooled too much; the consequence was, that it fermented very badly, and finally ran into acidity.

Soon after the yeast has been mixed with the wort, an intestine motion begins to appear in the liquid; air

Brewing.

bubbles separate from it, and a froth collects slowly upon the surface. This froth is of a yellowish gray colour. At first it has the appearance of cream; but in a few days it collects in considerable quantities, especially if the weather be warm. At the same time the temperature of the wort increases, and a very considerable quantity of carbonic acid gas is given out by it. The increase of temperature which takes place during the fermenting of ale may be stated, at an average, to amount to 12° or 15°. Sometimes it amounts to 20°, and sometimes does not exceed 5°. But in such cases there is generally some fault in the skill of the brewer. But the following table, exhibiting the highest temperatures of different ales during their fermentation, will satisfy the reader of these changes of temperature better than any general explanation:

Quantity of Wort fermented in two Tuns. In Barrels.	Date at which it was let into the fermenting Tuns.	Temperature at that time.	Temperature when at the highest point of Fermentation.	Date at which this Temperature took place.	Strength of Wort when let into fermenting Tuns, in lbs. per Barrel.	Quantity of Yeast added in Gallons.
10-83	March 10.	50°	63°	March 17.	88-75	4
14-944 in 1 tun.	March 17.	55	61	March 21.	85-62	2½
14-8055	March 24.	46	68	April 2.	78-125	3½
14-6388 in 1 tun.	March 29.	57	70	April 2.	80-625	2-83
14-722	March 31.	56	71	April 3.	73-75	2-83
17-43 in 1 tun.	April 4.	51	64	April 10.	65-00	2-83
8-72 in 1 tun.	April 6.	50	65	April 13.	93-75	3½

We shall now give some examples of the change of temperature by fermentation, when the brewings were conducted in summer, and of course assisted by the heat of the weather.

Quantity of Wort fermented in Barrels.	Date of letting it into the fermenting Tun.	Temperature at that time.	Temperature when at highest.	Date of ditto.	Strength of Wort in lbs. per Barrel.	Yeast used in Gallons.
9-75	May 24.	51°	71°	May 30.	95-93	1
11-4782	May 28.	49	72	June 2.	91-56	1
9-25	May 31.	46	67	June 6.	89-37	1
10-2777	June 4.	46	67½	June 13.	105-82	1
10-5	June 7.	44	71	June 15.	102-187	1
10-2222	June 11.	55	82	June 15.	110-0	1

13-5	June 21.	53	67½	June 25.	61-25	1

We shall likewise give the result of two brewings with raw grain made also during summer.

Quantity of Wort fermented in Barrels.	Date of letting it into the fermenting Tun.	Temperature at that time.	Temperature when at highest.	Date of ditto.	Strength of Wort in lbs. per Barrel.	Yeast used in Gallons.
10-5555	June 26.	48°	62°	July 1.	56-25	1
14-3055	July 6.	58	68	July 8.	72-5	1½

From the preceding tables we see that the length of time which elapses before the fermentation reaches its acme, supposing this to be measured by the temperature, varies very considerably. The shortest interval in the table is three days, and the longest nine days; the average of the whole is very nearly six days, which is exactly the mean between the longest and the shortest times. If the reader will glance his eye over the tables, he will perceive that, in general, the higher the temperature of the wort is when let down into the fermenting tuns, the more rapidly does the fermentation come on. As the worts were cooled by exposure to the greatest cold of the night, and as the coolers were screened from the radiation of heat, the temperatures given to the third column of the preceding tables may be considered as measuring very nearly the greatest degree of cold which took place in Edinburgh at the dates contained in the second column. It follows, as might have been expected, that the warmer the weather the more rapid is the fermentation. And hence the advantage of letting down the worts rather warm in cold weather, and cooling them down as much as possible in warm weather. For this purpose we cannot too much recommend coolers which can occasionally be uncovered altogether, and exposed to the unclouded sky. A roof, perhaps, might be contrived, composed of very light materials, which might be easily slid off, or which might turn upon a pivot. For a roof would be occasionally necessary to screen the worts from rain. In warm weather, brewing should be confined to clear and unclouded days, when the cooling process could be carried farthest of all. We have little doubt that wort might easily be cooled down to the freezing point, if requisite, in our warmest summer weather.

Little can be said about the length of time during which the fermentation of the ale lasts, because it varies very much according to the heat of the weather, and the degree to which the wort has been cooled down. The following table will give some idea of the length of time which elapsed during the fermentations contained in the preceding tables:

Brewing.
Theory of
fermenta-
tion

The theory of fermentation has occupied the attention of chemists ever since the manufacture of ale began to be attended to by men of science, but it is only of late that much light has been thrown upon the subject. Lavoisier was the first person who attempted to give any thing like a theory of this intricate process. He attempted to determine the composition of common sugar, a substance which may be fermented just as well as the soluble part of malt, and which yields similar products. He endeavoured, likewise, to determine the constituents of alcohol, the substance formed by fermentation. With these data, and with a knowledge of the composition of water and carbonic acid, he formed a plausible theory, which was valuable as a first approximation, though there can be little doubt that it was erroneous in every particular. Since that time, several experiments on the subject have been made by Thenard. Guy-Lussac and Thenard, and Berzelius, have determined the constituents of sugar with much care; and Theodore de Saussure has made very elaborate, and we believe accurate, experiments on the composition of alcohol. These facts will enable us to form a conception of what takes place during fermentation. We shall first state the general theory, as resulting from experiments on common sugar, and then give some experiments which we ourselves have made on the saccharine matter of malt.

If a weak solution of sugar in water be kept in a warm place, it will ferment of itself, and be converted into a spirituous liquor. This we have tried more than once, and always successfully, provided the weather was warm. A solution of sugar of grapes in water ferments still more speedily. This is said likewise to be the case with sugar of starch, and, of course, with the saccharine matter of malt. In our general view of fermentation, then, we may leave out of view the small quantity of yeast; because it is not absolutely necessary, but seems merely to render the effect more rapid, and consequently prevent the change of the liquid into acidity, which almost always takes place when the fermentation is slow.

When the fermentation is complete, the sugar disappears altogether, and two new substances are found in its place, namely, carbonic acid and alcohol. All that happens, then, is the resolution of sugar into the two new substances, carbonic acid and alcohol. It is requisite to know how much of each of these substances is formed from a given weight of sugar.

According to Lavoisier's experiments, 100 parts of sugar yielded, when fermented,

Alcohol.....57.70
Carbonic acid.....35.34

He does not give us the specific gravity of his alcohol, but it could scarcely be less than 0.825; for when his experiments were made, alcohol of greater strength was scarcely known. Now, such alcohol contains at least 11 per cent. of water, for that quantity has been actually extracted from it. From Saussure's experiments, it is probable that the real quantity of water contained in alcohol of the specific gravity 0.825, is 18.387 per cent. or almost a fifth. On this supposition sugar, according to Lavoisier's experiments, yields

Alcohol.....47.1
Carbonic acid.....35.34
82.44

or, per cent.

Alcohol.....57.1
Carbonic acid.....42.9
100.0

Thenard mixed 60 parts of yeast with 300 parts of sugar, and fermented the mixture at the temperature of 59°. He informs us that, in four or five days, all the saccharine matter had disappeared. The quantity of carbonic acid evolved amounted by weight to 94.6 parts. It was perfectly pure, being completely absorbed by water. The fermented liquid being distilled, yielded 171.5 parts of alcohol of the specific gravity 0.822. When the residue of the distillation was evaporated, 12 parts of a nauseous acid substance remained, and 40 parts of the yeast still continued unaltered in appearance, though Thenard assures us that it had lost the whole of its azote. Thus the products of the fermentations were,

Alcohol of 0.822.....171.5
Carbonic acid.....94.6
Nauseous residue.....12.0
Residual yeast.....40.0
318.1
Loss.....41.9
Total.....360.0

But as the nauseous residue and residual yeast nearly make up the quantity of yeast employed, let us consider only the products of decomposed sugar, supposing the loss to be proportionally divided between the carbonic acid and alcohol. Now, alcohol of the specific gravity 0.822 contains one tenth of its weight of water, which can be separated from it; and if we suppose, with Saussure, that absolute alcohol contains 8.3 per cent of water, then the products of sugar decomposed by fermentation, according to Saussure's experiments, are as follows:

Alcohol.....47.70
Carbonic acid.....35.34
83.04

or, in 100 parts,

Alcohol.....57.44
Carbonic acid.....42.56
100.00

This result approaches so nearly that of Lavoisier, that there is reason to suspect that the coincidence is more than accidental.

According to the experiments of Thenard and Guy-Lussac, sugar is composed of

Carbon.....42.47
Oxygen and hydrogen in the same proportion
as in water.....57.53
100.00

According to one analysis of Berzelius it is composed of

Hydrogen.....6.802
Carbon.....44.115
Oxygen.....49.083
100.000

and, according to another, of

Hydrogen.....6.891
Carbon.....42.704
Oxygen.....50.405
100.000

Alcohol, according to the analysis of Saussure, is composed of

Hydrogen.....13.70 or 3 atoms.
Carbon.....51.98 or 2 atoms.
Oxygen.....34.32 or 1 atom.
100.00

And carbonic acid is composed of

Carbon.....27.3 or 1 atom.
Oxygen.....72.7 or 2 atoms.

Hence it is obvious that sugar can be resolved into alcohol and carbonic acid only, on the supposition that it contains three atoms of oxygen, three atoms of carbon, and

Brewing. three atoms of hydrogen ; proportions which do not accord with any of the analyses stated above. Supposing its composition to be so, the weight of each of the constituents per cent. is as follows :

Hydrogen	6.66
Carbon	40.03
Oxygen.....	53.31
	100.00

On this supposition an integrant particle of sugar contains nine atoms, namely, three of oxygen, three of carbon, and three of hydrogen ; which are capable of arranging themselves differently, so as to form an integrant particle of alcohol containing six atoms, and an integrant particle of carbonic acid containing three atoms.

An integrant particle of sugar is composed of

	Oxygen. 3 Atoms.	Carbon. 3 Atoms.	Hydrogen. 3 Atoms.
A particle of alcohol of.....	1	2	3
A particle of carbonic acid of..	2	1	0
	3	3	3

The weight of a particle of alcohol is.....2.877

The weight of a particle of carbonic acid.....2.751

According to these numbers, 100 parts of sugar ought by fermentation to be decomposed into

Alcohol.....	50.76
Carbonic acid.....	49.24
	100.00

or it ought to form very nearly equal weights of each of these constituents.

This explanation of fermentation, though in some points hypothetical, must be admitted to approach pretty near the experiments made upon the subject. These experiments are attended with so much difficulty, that rigid accuracy cannot be expected. In all likelihood, we can never arrive at the truth by any other method than that which we have followed upon this occasion. Nor will this method be any longer doubtful, as soon as it is ascertained with precision that sugar can be resolved into alcohol and carbonic acid, and as soon as we know the proportions of the two substances evolved. We conceive that both Lavoisier and Thenard have stated the quantity of carbonic acid too low, from not being aware that the whole of the sugar is never decomposed by fermentation. This we conclude from some experiments of our own, made on a large scale, of which we shall now proceed to give an account.

Nine different brewings of pure malt were made. The worts were weak, and they were fermented as strongly as possible by means of large quantities of yeast, added at intervals, as is practised by the distillers. The following table exhibits the specific gravity of these worts before and after the fermentation was over :

Specific gravity of the wort.	Specific gravity of ditto after fermentation.
1.040	1.0014
1.056	1.0016
1.050	1.000
1.0492.....	1.0012
1.0465.....	1.0045
1.045	1.0047
1.0465.....	1.0007
1.051	1.0007
1.0524.....	1.0004

From this table we see that only one of the worts was reduced by fermentation so low as the specific gravity of pure water. As a good deal of alcohol was evolved in each by the fermentation, it is obvious that they must have all contained a certain portion of saccharine matter undecomposed, notwithstanding the violence of the fermentation, which elevated the temperature of the worts more than 50 degrees. On evaporating a portion of the worts of each of

these brewings, we obtained a quantity of undecomposed saccharine matter, which amounted, at an average, to one fifth of the quantity originally present. At first they contained, on an average, 45 lbs. per barrel of saccharine matter. The *spent wash*, after distillation, contained still 9 lbs. per barrel. This liquor was capable of being fermented a second time, and of yielding more spirits.

But as these worts were very weak, and as they were fermented in very advantageous circumstances, and in much greater quantities than either Lavoisier or Thenard could have employed in their experiments, we do not conceive that more than four fifths of the sugar which they employed in their experiments could have been decomposed. Now, if to the carbonic acid actually developed in their trials we add a fifth part, the number will approach very nearly to the one which we have deduced from the supposition that sugar is decomposed by fermentation into an integrant part of alcohol and an integrant part of carbonic acid.

On comparing the quantity of alcohol of 0.825 obtained in our experiments from the quantity of saccharine matter actually decomposed by fermentation, the result was, that 100 parts of saccharine matter yielded almost exactly 50 parts of such alcohol. This would amount to about 40.9 parts of real alcohol. There can be no doubt that a portion of the alcohol was lost during the distillation, which was conducted in the rapid way followed some years ago by the distillers in Scotland. If we suppose one fifth to have been lost, which is probably not much beyond the truth, the real produce of alcohol from the saccharine matter of malt would be almost exactly one half of its weight, which it ought to be, according to the preceding supposition, that it is decomposed into alcohol and carbonic acid.

When the fermentation is languid, it is customary to beat in the yeast which has collected on the top ; that is to say, the whole is stirred till the wort and yeast are thoroughly mixed.

5. The last step of the process of brewing is called *Cleansing*. When the violence of the fermentation is over, the head of yeast which covers the top of the fermenting tun diminishes in height by the gradual escape of the carbonic acid gas, which heaved it into bubbles. If the wort were allowed to remain in the gyle-tun after this has happened, the yeast would again mix with it ; and the consequence would be a disagreeable bitter taste, known among brewers by the name of *yeast bitter*. The fermentation would likewise continue, though in a languid manner, and the ale would soon run into acidity. These accidents are prevented by drawing off the ale into small casks. And this is called *cleansing*. The casks are filled quite full, and left with their bungs open. The drawing off of the ale from the gyle-tun lowers its temperature, and, of course, checks the fermentation. On this account the cleansing is sometimes practised in summer, when the elevation of temperature in the wort is at its height.

We have repeatedly observed a curious circumstance during the cleansing, not very easily accounted for. If we take the temperature of the ale at the upper surface of the gyle-tun, and then observe the temperature of the ale when it flows from the stop-cock at the bottom of the tun, we shall generally find it one or two degrees hotter in this latter place than at the former. We ought naturally to expect the highest temperature at the top of the gyle-tun.

The ale still continues to ferment after it is put into the small casks ; but as these casks are always kept full, the yeast, as it comes to the surface, flows out at the bung, and thus separates altogether from the beer. It is this separation that has induced brewers to distinguish it by the name of *cleansing*. In these casks, then, the yeast divides itself into two portions. The greatest part rises

Brewing. up with the carbonic acid evolved, and flows out at the bung-hole; while another portion subsides to the bottom, and constitutes what is called the dregs of the beer. It is essential to the cleansing that the casks should be always full, otherwise the yeast will not run off, and the beer will not become transparent. This object is accomplished in small breweries by a man constantly going round, and filling up the casks as they *work down*. But in the London breweries there is an ingenious mechanical contrivance which answers the purpose perfectly.

When the fermentation has subsided, the beer will in general be found transparent. It is bunged up in the casks and preserved for sale; or in London, where the quantity is too great for this, the beer is removed into

large stone vats, capable of holding several thousand barrels, from which it is gradually distributed to the consumers.

In London, where the beer is usually sent to the public-houses as soon as the fermentation is over, and before it has had time to become fine, it is usual to send along with it a quantity of *finings*, as it is called; that is, a solution of isinglass in weak sour beer, made from a fourth mash of the same malt. The publican puts a certain quantity of this into every cask. It forms a kind of web at the surface of the liquid; and, gradually sinking to the bottom, carries with it all the flocculent matter, and leaves the beer transparent.

We shall terminate this chapter with a table exhibiting Tables of the results obtained by brewing with malt made from a considerable number of different varieties of barley and big.

Difference
between
beer and
ale.

Porter.

The English word *ale* is obviously the same with the Swedish word *öl*, which is applied to the same kind of fermented liquor; while the word *beer* is synonymous with the German word *bier*. These two words in Great Britain are applied to two liquors obtained by fermentation from the malt of barley; but they differ from each other in several particulars. Ale is light-coloured, brisk, and sweetish, or at least free from bitter; while beer is dark-coloured, bitter, and much less brisk. What is called *porter* in England is a species of beer, and the term *porter* at present signifies what was formerly called *strong beer*. The original difference between these two liquids was owing to the malt from which they were prepared. Ale malt was dried at a very low heat, and consequently was of a pale colour; while beer or porter malt was dried at a higher temperature, and had of consequence acquired a brown colour. This insipient charring had developed a peculiar and agreeable bitter taste, which was communicated to the beer along with the dark colour. This bitter taste rendered beer more agreeable to the palate, and less injurious to the constitution, than ale. It was consequently manufactured in greater quantities, and soon became the common drink of the lower ranks in England. When malt became high priced in consequence of the heavy taxes laid upon it, and the great increase in the price of barley which took place during the war of the French revolution, the brewers found out that a greater quantity of wort of a given strength could be prepared from pale malt than from brown malt. The consequence was, that pale malt was substituted for brown malt in the brewing of porter and beer. We do not mean that the whole malt employed was pale, but a considerable proportion of it. The wort of course was much paler than before, and it wanted that agreeable bitter flavour which characterized porter, and made it so much relished by most palates. The porter brewers endeavoured to remedy these defects by several artificial additions. They prepared an artificial colouring matter, by heating a solution of coarse sugar in an iron boiler till it became black, and was reduced to the consistency of treacle. The smoke issuing from it was then set on fire, and the whole was allowed to burn for about ten minutes, when the flame was extinguished by putting a lid on the vessel. This substance was mixed with a certain quantity of water before it was cold. The porter is coloured by adding about two pounds of this colouring matter for every barrel of wort while in the gyle-tun. Some brewers make their colouring matter with infusion of malt instead of sugar; and in 1809 M. de Roche took out a patent for preparing the colouring matter from the husks of malt, by burning them like coffee, and then infusing them in water. We believe that all these colouring matters are of the same nature; of course the brewer ought to employ that one of them which is cheapest.

To supply the place of the agreeable bitter which was communicated to porter by the use of brown malt, various substitutes were tried. Quassia, cocculus indicus, and we believe even opium, were employed in succession; but none of them were found to answer the purpose sufficiently. Whether the use of these substances be still persevered in we do not know, but we rather believe that they are not, at least by the London porter brewers.

It was this change in the use of the malt which occasioned the great falling off in the London porter, which has been so much complained of, and ascribed to so many causes. We do not believe that the schemes of Mr Jack-

son, of notorious memory, though they enriched himself, produced the injurious effects upon the London breweries that have been ascribed to them. This man, whose character was notorious, kept an apothecary's shop on Tower-Hill; and speculating on the means of amassing a speedy fortune, he hit upon the idea of brewing beer from various drugs instead of malt and hops. But instead of commencing practical brewer himself, he struck out the more profitable trade of teaching his process to the London brewers. Mrs Piozzi informs us, that even from one great brewer he contrived to realize an ample fortune. His methods must have been practised upon a considerable scale for some time; but we have no doubt that they have been all abandoned long ago. It was the French war, and the enormous tax upon malt, that was the real cause of the deterioration of the quality of London porter. Nor will it ever recover its former good qualities, till the tax on malt is reduced to its former rate; or unless the price of porter be greatly enhanced, which is not likely to happen. We have sometimes thought that if quassia were reduced to powder, and burnt like coffee, it might probably be employed with great advantage, both as a colouring matter of porter, and as likely to furnish the agreeable bitter, at present considered as peculiar to brown malt.

The quantity of malt employed annually in Great Britain, in brewing ale and beer, may be easily deduced from the annual statements of the amount of the malt tax, printed by order of the House of Commons.

In the year 1813 the gross produce of the malt tax for England was L.4,188,450. 6s. 9d. Now, as this duty is levied at the rate of four shillings and fourpence per bushel, it follows that the quantity of malt made in England, and charged with duty, amounted to 2,416,384.81 quarters. If we admit that the quantity of malt actually made exceeds by five per cent. what is charged with duty, in that case the whole malt actually made in England during the year 1813 was 2,537,204 quarters.

In Scotland the actual receipts during the year 1813 were L.134,106. 12s. 0½d. This, at the rate of three shillings and eightpence and half a farthing per bushel, which is the rate of the duty for Scotland, makes the number of the quarters of malt made in that kingdom during the year 1813 amount to 91,436.32. We cannot here make the allowance of five per cent. for the increase of bulk from malting, because we do not know what portion of this malt was made from English and what from Scotch barley. But as the duty in the Highlands of Scotland is lower than in the Lowlands, and as it cannot be doubted that a very considerable proportion of the barley malted in Scotland is the growth of England, perhaps we shall not err very far if we reckon the whole of the malt actually made in Scotland in 1813 at 100,000 quarters, which is only one twenty-sixth part of the whole malt made in Great Britain. Hence it follows that four times as much beer is consumed in England as in Scotland, in proportion to the population of the two countries. This is a prodigious advantage in favour of Scotland; for there cannot be a doubt that beer is inferior in salubrity to plain water as a beverage, and that, if the money spent by the common people in England on beer were employed to buy food, they would be much more healthy, stout, and happy, than they are at present.

In the year 1814 the gross receipts of the malt tax in England amounted to L.4,772,332. 5s. 5½d. This, at the rate of four shillings and fourpence per bushel, indicates 2,753,268.6 quarters of malt; and, making an allowance of five per cent. it follows that the whole malt made in England in 1814 amounted to 2,890,932 quarters.

In Scotland, during the same year, the gross receipts

ewing. on the malt duty amounted to L.125,787. 7s. 10 $\frac{1}{2}$ d. which, at the rate of three shillings and eightpence one eighth per bushel, indicates 85,521.18 quarters of malt. We may increase this on account of the increase of malt not reckoned in the tax, and on account of the tax in the Highlands being lower than in the Lowlands, to 90,000 quarters of malt, which is a tenth less than the quantity malted in 1813, while, in England, the quantity malted had increased considerably. Thus it appears that the whole quantity of malt made in Great Britain during the year 1814 was 2,980,932 quarters.

Malt made in 1813, in quarters.....2,637,204

Ditto in 1814.....2,980,932

Mean.....2,809,068

But this consumption of barley, enormous as it is, by no means gives us the whole of that grain consumed annually in Great Britain in the manufacture of spirituous liquors. For the distillers employ at least two thirds of the barley which they use in the state of raw grain. Now this quantity does not pay any malt tax, and, of course, is not included in the preceding estimate. It might be possible to form an idea of this quantity from the duty levied upon spirits, though such an inquiry would be foreign to the subject of this article.

But perhaps the following table, exhibiting the quantity of porter brewed by the thirteen principal houses in London, during nine years, will give the reader a more accurate conception of the extent to which the trade is carried in this country.¹

Quantity Brewed in One Year, ending	July 1807.	July 1808.	July 1809.	July 1810.	July 1811.	July 1812.	July 1813.	July 1814.	July 1815.

To form a proper estimate of the quantity of porter contained in this table, it is necessary to know that the London barrel contains thirty-six gallons.

The usual limits of the wort of strong ale in this country may be stated at from 60 to 120 pounds per barrel, or from the specific gravity 1.064 to 1.1275 at the temperature of 60°. The highest-priced ales also are not always the strongest, because the price depends in a great measure on the reputation of the brewer. The fermentation of ale is not carried far; and the consequence

is, that a considerable portion of the saccharine matter still remains in the liquid, apparently unaltered. By means of the infusion of nut-galls, too, traces of starch may be still detected in strong ale, even after it has been kept for some time in bottles. The annexed table exhibits the original strength of the wort before the fermentation began, and likewise the diminution of specific gravity produced by the fermentation, or the *attenuation*, as this diminution is termed by brewers and distillers.

¹ There are many other porter brewers in London besides those whose names are contained in this table. The following were the seven next in order to those given in the table for 1812, with the quantity of porter manufactured by each:

Martineau & Co.....	24,143 barrels.	Tickells.....	18,071 barrels.
Hodgson.....	24,143	Dickinson.....	16,292
Pryors.....	20,210	Green & Co.....	14,090
Starkey.....	18,136		

If we were to give an opinion respecting the different modes followed in the different houses, we would place Martineau at the head of the trade in point of accuracy and skill.

The following table exhibits the quantity of strong ale brewed by the seven principal houses in London, in the year ending the 5th of July 1815:

Stretton & Co.....	27,094 barrels.	Hale & Co.....	10,134 barrels.
Wyatt.....	22,146	Ball & Co.....	7,985
Charrington & Co.....	20,444	Thorpe & Co.....	5,433
Goding & Co.....	14,491		

² During the last four years in the table we have substituted Cox & Campbell.

³ During the last four years we have substituted Hollingsworth & Company.

As a certain quantity of alcohol is evolved in the ale by the fermentation, it is obvious that the last column is not quite accurate. The real quantity of saccharine matter in each of these also must be greater than what is indicated in that column, because the effect of the saccharine matter, in increasing the specific gravity of the ale, is counteracted by the alcohol, which tends to diminish that specific gravity. By casting the eye over the preceding table, it will be seen that the attenuation does not follow the ratio of the strength. It was greatest of all in the third, and least in the first brewing. These brewings being the same with those given in the fourth chapter, in order to illustrate the quantity of yeast used in fermenting, the reader, by comparing the two tables together, will be able to form some conclusions respecting the effect of

different quantities of yeast, and different temperatures upon the attenuation of strong ale, Brewing

Porter is much weaker than strong ale. The average specific gravity of porter wort, according to Shannon, as of strength deduced by the saccharometer, is 1.0645, which indicates 60 pounds per barrel of saccharine extract. Hence the reason why it is so much less glutinous and adhesive than strong ale. The fermentation which porter undergoes is, we believe, much less than that of ale; but we have no very accurate information on the subject. According to the experiments of Mr Brande, brown stout, which is the strongest porter made in London, contains 6.8 per cent. by measure, of alcohol of the specific gravity 0.825. If he had given us the specific gravity of this porter before distillation, it would have enabled us to determine in some measure the error in the attenuation, as indicated by the saccharometer.

The porter brewers in London use three kinds of malt; namely pale malt, amber malt, and brown malt. These three are mashed separately, and the worts from each are afterwards mixed together in the same fermenting vessel. In some breweries, as in that of Barclay and Perkins in the Borough, there are three separate mash-tuns. In other breweries, the custom is to mash one kind of malt the first day, another kind the second day, and a third kind the third day. The first day's wort is put into the fermenting vessel, and mixed with yeast; and the other two worts are added to it successively as they are formed. Hence it is very difficult to determine with accuracy the strength of the worts in the London breweries. It could only be done by knowing the quantity of wort from each malt, and its specific gravity when let into the fermenting vessel. We have had an opportunity of determining the strength of the porter wort in all the principal breweries in London. The average specific gravity of brown-stout wort is 1.0624. The wort of the best common porter is of the specific gravity 1.0535, that of the worts of the weakest is as low as 1.0374. The average specific gravity deduced from twenty brewings was 1.0500. Such wort contains about 46.4 lbs. per barrel of saccharine matter. Judging from the taste of some of the worts, quassia seems to be employed in considerable quantity by some of the brewers, and much more sparingly, if at all, by others. The fermentation of porter is carried on with considerable rapidity, so that it is over in two or three days. The specific gravity of the porter is usually brought down to 1.013 or 1.017. The specific gravity of the best brown-stout, after standing some months in the bottle, is 1.0106. The proportion of pale and brown malt used in the different houses varies. One of the best brewers in London uses nearly two parts pale malt to one part brown. (L.)

EXPLANATION OF THE PLATES.

Figs. 1 and 2, Plate CXXX., explain the arrangement of the utensils and machinery in a porter brewery on the largest scale; in which, however, it must be observed that the elevation, fig. 1, is in a great degree imaginary as to the plane upon which it is taken; but the different vessels are arranged so as to explain their uses most readily, and at the same time to preserve, as nearly as possible, the relative positions which are usually assigned to each in works of this nature.

The malt for the service of the brewery is stored in vast granaries or malt-lofts, usually situated in the upper part of the buildings. Of these, we have only been able to represent one at A, fig. 1; the others, which are supposed

to be on each side of it, cannot be seen in this view. Immediately beneath the granary A is the mill, in the upper floor of which are two pair of rollers for bruising or crushing the grains of the malt. (An enlarged representation of the rollers is given at figs. 3 and 4.) In the floor beneath the rollers are the mill-stones *b b*, where the malt is sometimes ground, instead of the simple bruising which it receives by passing between the rollers.

The malt, when prepared, is conveyed by a trough into a chest, *d*, from which it can be elevated by the action of a spiral screw *e* (see also figs. 5 and 6) into the large chest or binn B, for ground malt, situated immediately over the mashing-tun D. The malt is reserved in the binn

Brewing. till wanted, and it is then let down into the mashing-tun, where the extract is obtained by hot water supplied from the copper G.

The water for the service of the brewery is obtained from the well E, by a lifting pump worked by the steam-engine; and the forcing-pipe *f* of this pump conveys the water up to the large reservoir or water-back F, placed at the top of the engine-house. From this cistern iron pipes are laid to the copper G, and also every part of the establishment where cold water can be wanted for cleaning and washing the vessels. The copper G can be filled with cold water by only turning a cock; and the water, when boiled therein, is conveyed by the pipe *g* into the mashing-tun D. It is introduced beneath a false bottom, upon which the malt lies, and, rising up through the holes in the false bottom, it extracts the saccharine matter from the malt; a greater or less time being allowed for the infusion, according to circumstances. The instant the water is drawn off from the copper, fresh water must be let into it, in order to be boiled ready for the second mashing; because the copper must not be left empty for a moment, otherwise the intense heat of the fire would melt the bottom. For the convenience of thus letting down at once as much liquor as will fill the bottom of the copper, a pan or second boiler is placed over the top of the copper, as seen in fig. 3, Plate CXXXI.; and the steam rising from the copper communicates a considerable degree of heat to the contents of the pan, without any expense of fuel. This will be more minutely explained hereafter.

During the process of mashing, the malt is agitated in the mash-tun, to expose every part to the action of the water. This is done by a machine contained within the mash-tun, and put in motion by the horizontal shaft H, leading from the mill. The mashing-machine is shown in fig. 1, Plate CXXXI. When the mashing is finished, the wort or extract is drained down from the malt, into a vessel I, of similar dimensions to the mash-tun, and situated immediately beneath, from which it is called the under-back. Here the wort does not remain longer than is necessary to drain off the whole of it from the tun above. It is then pumped up by the three-barrelled pump *k*, into the pan at the top of the copper, by a pipe which cannot be seen in the plate.

The wort remains in the copper pan until the water for the succeeding mashes is discharged from the copper. But this waiting is no loss of time, because the heat of the copper, and the steam arising from it, makes the wort, which had become cooler, ready for boiling. The instant the copper is empty, the wort is let down from the pan into the copper, and the second wort is pumped up from the under-back into the copper pan. The proper proportion of hops is thrown into the copper through the near hole, and then the door is shut down, and screwed fast, to keep in the steam, and cause it to rise up through pipes into the pan; and by bubbling up through the wort in the pan, it communicates so much heat that it is soon ready for boiling in its turn; for it is to be observed, that the different worts follow each other through all the different vessels with the greatest regularity, so that there is no loss of time, but every part of the apparatus is constantly employed. When the boiling of the wort has continued a sufficient time to coagulate the grosser part of the extract and to evaporate part of the water, the contents of the copper are run off through a large cock into the jack-back K, which is a vessel of sufficient dimensions to contain it, and provided with a bottom of cast-iron plates, perforated with small holes, through which the wort drains and leaves the hops. The hot wort is drawn off from the jack-back through the pipe *h* by the three-barrelled pump, which throws it up to the coolers L, this pump being made

Brewing. with different pipes and cocks of communication, to serve all the purposes of the brewery except that of raising the cold water from the well. The coolers L are very shallow vessels, built over one another in several stages; and that part of the building in which they are contained is built with open lattice-work on all sides, to admit the free current of air. When the wort is sufficiently cooled to be put to the first fermentation, it is conducted in pipes from all the different coolers to the large fermenting vessel or gyle-tun M, which, with another similar vessel behind it, is of sufficient capacity to contain all the beer of one day's brewings.

When the first fermentation is concluded, the beer is drawn off from the great fermenting vessel M into the small fermenting casks or cleansing vessels N, of which there are a great number in the brewery. They are placed four together, and to each four a common spout is provided to carry off the yeast, and conduct it into the troughs *u* placed beneath. In these cleansing vessels the beer remains till the fermentation is completed, and it is then put into the store-vats, which are casks or tuns of an immense size, where it is kept till wanted, and is then drawn off into barrels and sent away from the brewery. The store-vats are not represented in the plate, but are of a conical figure, and of different dimensions, from fifteen to forty feet diameter, and usually twenty feet in depth. The steam-engine which puts all the machinery in motion is explained by the figure. On the axis of the large fly-wheel is a bevelled cog-wheel, which turns another similar wheel upon the end of a horizontal shaft, which extends from the engine-house to the great horse-wheel, which it turns by means of a cog-wheel. The horse-wheel puts in motion all the pinions for the mill-stones *bb*, and also the horizontal axis which works the three-barrelled pump *k*. The rollers *aa* are turned by a bevelled wheel upon the upper end of the axis of the horse-wheel, which is continued for that purpose; and the horizontal shaft H, for the mashing engine, is driven by a pair of bevelled wheels. There is likewise a sack-tackle, which is not represented. It is a machine for drawing up the sacks of malt from the court-yard to the highest part of the building, whence the sacks are wheeled on a truck to the malt-loft A, and the contents of the sacks are thrown in.

The horse-wheel is intended to put in horses occasionally if the steam-engine should fail; but these engines are now brought to such perfection that it is very seldom any accidents occur with them.

Fig. 2, Plate CXXX., is a representation of the fermenting-house at the brewery of Messrs Whitbread and Company, Chiswell Street, London, which is by far the most complete in its arrangement of any work of the kind, and was erected after the plan of Mr Richardson, who conducts the brewing at those works. The whole of fig. 2 is to be considered as devoted to the same object as the large vessel M and the casks N, fig. 1. In fig. 2, *r* is the pipe which leads from the different coolers to convey the wort to the great fermenting vessels or squares M, of which there are two, one behind the other; *ff* represents a part of the great pipe which conveys all the water from the well E, fig. 1, up to the water cistern F. This pipe is conducted purposely up the wall of the fermenting-house, fig. 2, and has a cock in it, near *r*, to stop the passage. Just beneath this passage a branch-pipe *p* proceeds and enters a large pipe *xx*, which has the former pipe *r* within-side of it. From the end of the pipe *x*, nearest to the squares M, another branch *nn* proceeds, and returns to the original pipe *f*, with a cock to regulate it. The object of this arrangement is to make all, or any part of, the cold water flow through the pipe *xx*, so as to surround the wort-pipe *r*, which is only made of thin copper, and lower the temperature of the wort passing through the pipe *r*,

Brewing. until, by the thermometer, it is found to have the exact temperature which is desirable before it is put to ferment in the great square M. By means of the cocks at *n* and *p*, the quantity of cold water which shall pass in contact with the surface of the pipe *r* can be regulated at pleasure, so as to have a command of the heat of the wort when it enters into the square.

When the first fermentation in the squares M is finished, the beer is drawn off from them by pipes marked *v*, and conducted by its branches *w* to the different rows of fermenting-tuns marked NN, which fill all the building. Between every two rows are placed large troughs to contain the yeast which they throw off. The plate shows that the small tuns are all placed on a lower level than the bottom of the great vessels M, so that the beer will flow into them, and, by standing in them all, will fill them to the same level. When they are filled, the communication-cock is shut; but as the working off of the yeast diminishes the quantity of beer in each vessel, it is necessary to fill them up again. For this purpose the two large vats OO are filled from the great vessels M before any beer is drawn off into the small casks N, and this quantity of beer is reserved at the higher level for filling up. The two vessels OO are in reality placed between the two squares M, but we have been obliged to place them so that they can be seen. Near each filling-up tun *o* is a cistern *t*, with a pipe of communication from the tun O, and this pipe is closed by a float-valve. The small cisterns *t* have always a communication with the pipes which lead to the small fermenting vessels N, and therefore the surface of the beer in all the tuns and in the cisterns will always be at the same level; and as this level subsides by the working off of the yeast from the tuns, the float sinks and opens the valve, so as to admit a sufficiency of beer from the filling-up tuns *o* to restore the surfaces of the beer in all the tuns, and also in the cistern *t*, to the original level. In order to carry off the yeast which is produced by the fermentation of the beer in the tuns OO, an iron dish or vessel is made to float upon the surface of the beer which they contain; and from the centre of this dish a pipe *o* descends and passes through the bottom of the tun, being filled through a collar of leather so as to be tight, at the same time that it is at liberty to slide down as the surface of the beer descends in the tun. The yeast flows over the edge of this dish, and is conveyed down the pipe to a trough beneath.

Beneath the fermenting house are large arched vaults P, built with stone, and lined with stucco. Into these the beer is let down when sufficiently fermented, and is kept till wanted. These vaults are used at Mr Whitbread's brewery instead of the great store-vats of which we have before spoken, and are in some respects preferable, because they preserve a great equality of temperature, being beneath the surface of the earth.

Figs. 3 and 4, Plate CXXX., represent the malt-rollers, or machine for bruising the grains of malt. A is the hopper into which the malt is let down from the malt-loft above, and from this the malt is let out gradually through a sluice or sliding-shuttle *a*, and falls between the rollers BD. These rollers are made of iron, truly cylindrical, and their pivots are received in pieces of brass let into iron frames, which are bolted down to the wooden frame of the machine. A screw E is lapped through the end of each of these iron frames; and by these screws the brasses can be forced forwards, and the rollers made to work closer to each other, so as to bruise the malt in a greater degree. G is the shaft by which one of the rollers is turned, and the other receives its motion by means of a pair of equal cog-wheels H, which are fixed upon the ends of the pivots, at the opposite ends of each of the rollers: *d* is a small

lever, which bears upon the teeth of one of these cog-wheels, and is thereby lifted up every time a cog passes. This lever is fixed on the extremity of an axis, which passes across the wood frame, and in the middle of it has a lever *c*, fig. 3, bearing up a trough *b*, which hangs under the opening of the hopper A. By this means the trough *b* is constantly jogged, and shakes down the malt regularly from the hopper A, and lets it fall between the rollers: *e* is a scraper of iron plate, which is always made to bear against the surface of the roller by a weight, to remove the grains which adhere to the roller.

Fig. 5 is the screw by which the ground or bruised malt is raised up, or conveyed from one part of the brewery to another. K is an inclined bar or trough, in the centre of which the axis of the screw H is placed; and the spiral iron plate or worm, which is fixed projecting from the axis, and which forms the screw, is made very nearly to fill the inside of the box. By this means, when the screw is turned round by the wheels EF, or by any other means, it raises up the malt from the box *d*, and delivers it at the spout G.

The screw is equally applicable for conveying the malt horizontally in the trough *k* as inclined; and similar machines are employed in various parts of breweries for conveying the malt wherever the situation of the works require.

Fig. 1, Plate CXXXI., is the mashing-machine. WW is the tun, made of wood staves, hooped together. In the centre of it rises a perpendicular shaft NN, which is turned slowly round by means of the bevelled wheels KI at the top. RR are two arms projecting from the axis, and supporting the short vertical axis S at the extremities, so that, when the central axis is turned round, it will carry the axle S round the tun in a circle. The axis S is furnished with a number of arms T, which are shown in fig. 2, and have blades placed obliquely to the plane of their motion. When the axis is turned round, these arms agitate the malt in the tun, and give it a constant tendency to rise upwards from the bottom.

The motion of the axis S is produced by a wheel Q on the upper end of it, which is turned by a wheel P fastened on the lower end of the tube O, which turns freely round upon the central axis N. On the upper end of the same tube O is a bevelled wheel M, receiving motion from a wheel L, which is fixed upon the end of the horizontal axis F, which gives motion to the whole machine. This same axis has a pinion G upon it, which gives motion to the wheel H, fixed upon the end of a horizontal axle, which at the opposite end has a bevelled pinion I working the wheel K, before mentioned. By this means the rotation of the central axis N will be very slow compared with the motion of the axis S, for the latter will make seventeen or eighteen revolutions on its own axis in the same space of time that it will be carried once round the tun by the motion of the axis N. At the beginning of the operation of mashing, the machine is made to move with a slow motion; but, after having wetted all the malt by one revolution, it is made to revolve quicker. For this purpose the ascending shaft A, which gives motion to the machine, has two bevelled wheels BC fixed upon a tube X, which is fitted upon the shaft. These wheels actuate the wheels D and E upon the end of the horizontal shaft F; but the distance between the two wheels B and C is such, that they cannot be engaged both at once with the wheels D and E; but the tube X, to which they are fixed, is capable of sliding up and down on the axis A sufficiently to bring either wheel B or C into action with its corresponding wheel E or D upon the horizontal shaft; and as the diameters of BE and CD are of very different proportions, the velocity of the motion of the machine can

Brewing. be varied at pleasure by using one or other: *b* and *c* are two levers, which are forked at the ends, and embrace collars at the ends of the tube X; and the levers being united by a rod, the handle *b* gives the means of moving the tube X and its wheels BC up or down to obtain the action of the different wheels.

Figs. 3 and 4 represent a large close copper. AA is the copper, and B the pan placed over it. The copper has a large tube E rising up from the dome of it, to convey the steam; and from the top of this four inclined pipes R descend, the ends being immersed beneath the surface of the water or wort contained in the pan. By this means the steam which rises from the copper issues from the ends of the pipes R, and rises in bubbles through the liquor in the pan, so as to heat it. In the centre of the copper is a perpendicular spindle *a*, which, at the lower end, has arms *dd* fixed projecting from it, and is turned round by a cog-wheel *b* at the upper end. From the arms *dd* chains are hung in loops, which drag round upon the bottom of the copper when the axis is turned; and this motion stirs up the hops to keep them from burning at the bottom: *fg* is a chain and roller to draw up the spindle *a* when the rowser is not wanted; and *ee* are iron braces proceeding from the outside of the copper, to retain the axis *a* firmly in the centre of the copper. D is the waste-pipe for carrying off the steam into the chimney when it is not required to heat the liquor in the pan. The copper represented in the drawing is made in the same manner as usual; but the fire is applied beneath it in a manner very different from the common brewing-coppers. The method was devised with a view to the burning or consuming of the smoke, and was employed in the brewery of Messrs Meux and Company, London, about the year 1803.

The fire-place is divided into two by a wall extended beneath the bottom of the boiler, as shown by Z in the plan, fig. 4, where the dotted circle A represents the bottom of the copper, and the circle X its largest part. The section in fig. 3 shows only one of these fire-places, of which C is the fire-grate. The raw coal is not thrown in through the fire-door in the manner of common furnaces, but is put into a narrow inclined box of cast-iron *h*, built in the brick-work, and shaped like a hopper. The coals contained in this hopper fill it up, and stop the entrance of the air so as to answer the purpose of a door; and the coals at the lowest part or mouth of the hopper are brought into a state of ignition before they are forced forwards into the furnace, which is done by introducing a rake or poker at *i*, just beneath the lower end of the hopper *h*, and forcing the coals forwards upon the grate bars C. Immediately over the hopper *h*, a narrow passage is left to admit a stream of fresh air along the top of the hopper to pass over the surface of the fuel which is burning at the lower end of the hopper *h*. By this means the smoke rising from that portion of fuel is carried forwards over the burning coals upon the grate C, and is thereby consumed. Beyond the grate bars *c*, a breast wall S is erected, to direct the flame upwards against the bottom of the boiler A, and thence descending under the bottom, the flame is received into the flues, which make each a half turn round the lower part of the copper, as shown in the plan at *tt*, and then enter the chimney or perpendicular flue W at the same point; the entrance being regulated by a damper to make the draught more or less intense. There is also a sliding door or damper E, which closes up the lower part of the chimney; and by means of these two dampers the fire under the copper can be regulated to the greatest precision; for by opening the damper F it admits the cold air to enter immediately into the chimney W, and thus take off the rapidity of the draught; VOL. V.

Brewing. and at the same time, by closing the dampers from the flues into the chimney, the intensity of the draught through the fire is checked, which is very necessary to be done when the contents of the copper are drawn off. Immediately over the fire-grate *c*, an arch of fire-bricks or stone *s* is placed beneath the bottom of the copper, to defend it from the intense heat. The chimney is supported on iron columns RR. Behind the fire-grate *c* is a cavity *r*, for the reception of the masses of scoræ which are always formed in so large a fire. They are pushed back off the grate into this receptacle with an iron hook as fast as they accumulate. The bottom of this receptacle is formed of sliding iron doors, which can be opened by drawing them out, and in this way the clinkers are discharged; or the whole of the fire may be driven back off the grate into this cavity, and will then fall through into the ash-pit and be removed into the copper, which is very necessary to be done when the copper is to be cooled, so that men may descend into it to clean out the sediment which is left after boiling the wort. For a more particular description of this method of setting boilers, see *Philosophical Magazine*, vol. xvii.

Fig. 6 represents one of the sluice-cocks which are used to make the communications of the pipes with the pumps or other parts of the brewery. BB represents the pipe in which the cock is placed. The two parts of this pipe are screwed to the sides of a box CC, in which a slider A rises and falls, and intercepts at pleasure the passage of the pipe. The slider is moved by the rod *a*, which passes through a stuffing-box in the top, the box which contains the slider, and has the rack *b* fastened to it. The rack is moved by a pinion fixed upon the axis of a handle *e*, and the rack and pinion is contained in a frame *d*, which is supported by two pillars. The frame contains a small roller behind the rack, which bears it up towards the pinion, and keeps its teeth up to the teeth of the pinion. The slider A is made to fit accurately against the internal surface of the box C, and it is made to bear against this surface by the pressure of a spring, so as to make a perfectly close fitting.

Fig. 5 is a small cock to be placed in the side of the great store-vats, for the purpose of drawing off a small quantity of beer, to taste and try its quality. A is a part of the stave or thickness of the great store-vat; into this the tube B of the cock is fitted, and is held tight in its place by a nut *aa* screwed on withinside. At the other end of the tube B a plug *c* is fitted, by grinding it into a cone, and it is kept in by a screw. This plug has a hole up the centre of it, and from this a hole proceeds sideways and corresponds with a hole made through the side of the tube when the cock is open; but when the plug *c* is turned round, the hole will not coincide, and then the cock will be shut. D is the handle or key of the cock, by which its plug is turned to open or shut it; this handle is put up the bore of the tube (the cover E being first unscrewed and removed), and the end of it is adapted to fit the end of the plug of the cock. The handle has a tube or passage bored up it to convey the beer away from the cock when it is opened, and from this the passage *f*, through the handle, leads to draw the beer into a glass or tumbler. The hole in the side of the plug is so arranged, that when the handle is turned into a perpendicular direction with the passage *f* downwards, the cock will be open. The intention of this contrivance is, that there shall be no considerable projection beyond the surface of the tun; because it sometimes happens that a great hoop of the tun breaks, and, falling down, its great weight would strike out any cock which had a projection; and if this happened in the night much beer might be lost before it was discovered. The cock above described being

Briançon almost wholly withinside, and having scarcely any projection beyond the outside surface of the tun, is secure from this accident.

Fig. 7 is a small contrivance of a vent peg, to be screwed into the head of a common cask when the beer is to be drawn off from it, and it is necessary to admit some air to allow the beer to flow. AA represents a portion of the head of the cask into which the tube B is screwed. The

top of this tube is surrounded by a small cup, from which project the two small handles CC, by which the peg is turned round to screw it into the cask. The cup round the upper part of the tube is filled with water, and into this a small cup D is inverted; in consequence, the air can gain admission into the cask when the pressure within is so far diminished that the air will bubble up through the water, and enter beneath the small cup D.

BRIANÇON, an arrondissement of the department of the Upper Alps, in France, 658 square miles in extent, and containing five cantons, twenty-seven communes, and 82,370 inhabitants. The chief place, a city of the same name, stands in an alpine situation on the river Durance, and is strongly fortified, having been considered as the key of the gate between France and Italy. It contains only 2976 civil inhabitants. Long. 6. 39. E. Lat. 44. 64. N.

BRIANSK, a circle in the Russian government of Orel, with a population of 68,540 persons. The chief place is the city of the same name, on the river Desna. It trades in iron, corn, hemp, flax, and oak-bark, and contains about 6000 inhabitants. Long. 34. 14. E. Lat. 53. 21. N.

BRIAREUS, in fabulous history, a giant, the son of Æther, Titan, or Cœlus, and Terra. This was his name in heaven; but on the earth he was called Ægeon. He was of singular service to Jupiter, when Juno, Pallas, Neptune, and the rest of the gods, endeavoured to bind him in chains and dethrone him; but he afterwards conspired with the rest of his gigantic brethren to dethrone the father of the gods. In adverting to this legend, Virgil describes him as having a hundred hands and fifty heads, and breathing out fire. The fable says that Jupiter, to punish him, thrust him under Ætna, and that, as often as he moves, the mountain belches out fire.

BRIBE, a reward given to pervert the judgment. The word is French, *bribe*, which originally denotes a bit, fragment, or relic of meat taken off the table; so that bribe imports as much as *panis mendicatus*, and still keeps up the idea of the matter of which bribes anciently consisted. Hence also the Spaniards use *bribar* and *brivar* for *begging*; and *brivia*, *brivoneria*, and *brivonismo*, for *beggary*. In the writers of the middle ages, a bribe given to a judge is called *quato litis*, and the receiver *campi particeps*, or *cambi particeps*; because the spoils of the field, or the profits of the cause, were thus shared with the giver.

BRIBERY, in *Law*, is a high offence, where a person in a judicial station takes any fee, gift, reward, or brockage for doing his office, except of the king. But, taken largely, it signifies the receiving or offering any undue reward to or by any person concerned in the administration of public justice, whether judge, officer, or other, to act contrary to his duty; and sometimes it signifies the taking or giving of a reward for public office.

In the East it is the custom never to petition any superior for justice, not excepting their kings, without a present. This is calculated for the genius of despotic countries, where the true principles of government are not understood, and it is imagined that there is no obligation due from the superior to the inferior, no relative duty owing from the governor to the governed. The Roman law, though it contained many severe injunctions against bribery, as well for selling a man's vote in the senate or other public assembly, as for the bartering of common justice, yet, by a strange indulgence in one instance, it tacitly encouraged this practice, by allowing the magistrate to receive small presents, provided they did not on the whole exceed a hundred crowns a year; not considering

the insinuating nature and gigantic progress of this vice, when once admitted. Plato, therefore, in his ideal republic, orders those who take presents for doing their duty to be punished in the severest manner; and by the laws of Athens, he who offered a bribe was prosecuted, as well as he who received it. In England this offence of taking bribes is punished, in inferior officers, with fine and imprisonment; and in those who offer a bribe, though it be not taken, the same. But in judges, especially the superior ones, it has always been looked upon as so heinous an offence, that Chief Justice Thorpe was hanged for it in the reign of Edward III. By a statute 11 Henry IV. it was enacted that all judges and officers of the king convicted of bribery should forfeit triple the bribe, be punished at the king's will, and be discharged from his service for ever.

BRICIANI, those of the order of that name. This was a military order, instituted by St Bridget, queen of Sweden, who gave them the rules and constitutions of the orders of Malta and St Augustin. This order was approved of by Pope Urban V.

BRICK, a kind of artificial stone made of baked clay.

1. The art of making bricks is so simple that it must have been practised in the earliest ages of the world; probably before mankind had discovered the method of fashioning stones to suit the purposes of building. The book of Genesis informs us, that burnt bricks were employed in the construction of Babel. Now, as this structure appears to have been raised about four hundred years after the period of the Flood, we may say, without much exaggeration, that the method of making bricks existed from the very origin of society. Bricks seem to have been in common use in Egypt while the Israelites were in subjection to that nation; for the task assigned them was the making of brick; and we are informed in Exodus that the Israelites built two Egyptian cities. No particulars are given in Scripture of the method of making bricks; but as straw was one of the ingredients, and as it very seldom rains in Egypt, it is probable that their bricks were not burnt, but merely baked by the heat of the sun. The same mode of making bricks seems still to be practised in the East; for the ruins of the tower near Bagdad are formed of unburnt bricks. We have seen specimens from that place; they are large, but thin, and have a brown colour. It is not at all likely that structures of unburnt brick should have been able to resist the weather since the time of Nebuchadnezzar; and hence it is probable that the tower in question was raised by the Arabs in comparatively modern times.

The art of brick-making was carried to considerable perfection by the Greeks. Pliny informs us that they made use of bricks of three different sizes, distinguished by the following names; *didoron*, or six inches long; *tetradoron*, or twelve inches long; and *pentadoron*, or fifteen inches long (lib. xxxv. c. 14). That the Romans excelled in the art of making bricks we have the amplest evidence, since brick structures raised at Rome 1700 years ago still remain as entire as when first built. Brick-making has been carried to great perfection by the Dutch, who have long been in the

ick. habit of forming their floors, and even in some cases of paving their streets with bricks. And it is remarkable how long their bricks will continue uninjured in such situations. Though brick-making has long been carried on in England, and especially in the neighbourhood of London, upon a very great scale, and though the process upon the whole is conducted in this country with very considerable skill, yet it must be acknowledged that English bricks are by no means so durable as Dutch bricks. We are disposed to ascribe this inferiority not so much to the nature of the materials employed in the manufacture of English bricks, as to the mode most frequently employed in London in building houses. Few of the London houses, comparatively speaking, are freeholds. Most of them are built upon ground let for a lease of a certain number of years, which seldom exceeds ninety-nine years. After the expiration of this period, the house becomes the property of the landlord who let the ground. Thus it becomes the interest of the builder to construct the house so that it shall last only as long as the lease. Hence the goodness of the bricks becomes only a secondary object. Their cheapness is the principal point. The object, therefore, of the brickmakers is not to furnish durable bricks, but to make them at as cheap a rate as possible. Accordingly, the saving of manual labour, and of fuel, has been carried by the makers of London bricks to very great lengths. We cannot but consider this mode of proceeding as very objectionable, and as entailing a much heavier expense upon London than would have been incurred had twice the original price been laid out upon the bricks when they were first used, and had the houses been constructed to last a thousand instead of a hundred years. No doubt, certain advantages attend these ephemeral structures. The inhabitants are enabled, once every century, to suit their houses to the prevailing taste of the day; and thus, there are no antiquated houses in London. But as the increase of the price of all the materials of building has more than kept pace with the increase of the wealth of individuals, it is to be questioned whether the houses are always improved when they are pulled down and rebuilt.

Nat and
kind of
clay 2. The best material for making brick is what in the English language is called *loam*, a term usually applied to a natural mixture of sand and clay. Such a mixture may be converted into brick without any addition whatever. Marl likewise answers the purpose of common bricks very well, indeed better than most other mixtures. Marl is a natural mixture of limestone and clay in variable proportions. Now, the more lime it contains, the better does it answer for a manure; and the less lime it contains, the more suitable it is to the brick-maker.

It would be in vain to attempt a particular detail of the constituents of clay, because they vary too much from each other to admit of any correct generalization. We believe, however, that clays very frequently consist of decomposed felspar, in which case we may conceive them as composed of about three parts of silica in the state of a very fine powder, and one part of alumina. This is the case with porcelain clay. Indeed, the porcelain clay of Cornwall appears incontrovertibly to be nothing else than decayed felspar, or perhaps felspar which never had assumed any other form than that of clay. The rock from which it is taken is an agglutinated mixture of quartz and this clay. The quartz is separated by washing. Such a rock might probably be converted into most beautiful brick, merely by cutting it out in the proper shape, and subjecting it to the requisite heat; or rather, by kneading the whole into a paste with the requisite quantity of water, moulding it into bricks, and then drying and burning them.

Potter's clay is a compound of

Lime.....	3.5
Oxide of iron.....	1.0
Water.....	18.0

	99.2
Loss.....	8

Total.....	100.0
------------	-------

When the clay proceeds from the decomposition of hornblende, as is likewise often the case, it contains about three parts and a half of silica, one of alumina, one of lime, and about one and a half of oxide of iron. Sometimes the grains of sand which exist in clay consist of fragments of felspar. In such cases the clay may be fused by heat.

No mixture of alumina and silica, in any proportions whatever, can be fused by the strongest heat which can be raised in our furnaces. Hence such mixtures are best adapted for making fire-bricks, crucibles, and glass-house pots. Stourbridge clay is such a mixture, blackened by coaly matter. It answers these purposes better than any other clay in England. It is a slate clay belonging to the coal formation, and contains interspersed coaly matter. There is a similar bed of clay upon the banks of the Calder, about ten miles east from Glasgow. Mr Buttray uses it to make the crucibles in which he fuses steel, a process requiring the most intense heat that can be raised in furnaces. Its quality seems fully equal to that of Stourbridge clay. Neither can a mixture of lime and alumina be fused, in whatever proportions the ingredients be mixed. But a mixture of silica, lime, and alumina, is very fusible, and the fusion is most readily effected when we employ two parts of silica to one of lime. The presence of oxide of iron also renders clay fusible, but not unless its proportion be much greater than ever is likely to occur in any clay used for the manufacture of bricks.

For making common bricks, the most durable mixture ought to be common clay and limestone or chalk. Perhaps the best proportions would be three parts of clay, and one part of limestone or chalk in powder. When such a mixture is exposed to heat, it would experience an incipient fusion, and would thereby be rendered much harder and denser than common bricks. The consequence would be, that it would imbibe much less water, and would therefore be much less liable to crack and fall to pieces in winter, than common bricks. For when water has insinuated itself into the pores of a common brick, and is converted into ice, it undergoes an expansion which dislocates the parts of the brick and reduces it to fragments. This is often conspicuously the case with tiles, which, from their exposed situation, are more liable to be soaked with water than common bricks. Hence also covering the surface of the brick with a coating of paint has a great tendency to preserve them from cracking and breaking. This practice is frequently followed in England.

It would be foreign to the object of this article to enter into any long details respecting the chemical investigations and the opinions entertained at different periods respecting the nature of clay. At first it was supposed to be a peculiar species of earth, but Hellot demonstrated that it consisted at least of two constituents; for sulphuric acid had the property of destroying its plastic nature, and of rendering it scarcely more adhesive than sand. The portion that remained behind did not effervesce with acids. It was not therefore of a calcareous nature. Mr Pott went a step farther; he showed, in the continuation of his *Lithogegnosia*, that sulphuric acid formed, with the por-

Brick.

Brick.

tion of clay which it dissolved, a salt possessing the properties of alum. In the year 1769 Baumé published his *Dissertation on Clays*, which he had drawn up in consequence of a premium offered by the Academy of Sciences at Bordeaux, for the best solution of the following question:—What are the principles and constituents of clay, and the natural changes which it experiences, and what are the methods of rendering it fertile? The academy did not consider Baumé's solutions as satisfactory. He published his Memoir, in consequence, as a kind of defiance. He had been employed along with Macquer in making numerous experiments on clay, with a view to the improvement of the porcelain manufacture in France. Guided by these experiments, he drew as a conclusion that clay is a mixture of two different substances: 1. Silica in a state of purity; 2. Silica combined with an underdose of sulphuric acid. It was the second of these constituents that gave to clay its fattish and plastic nature. Margraaf had long before (in 1756) demonstrated that the ingredient of clay which Baumé took for a salt, and which he affirmed was soluble in water, was a peculiar species of earth, different from every other, which constitutes the basis of alum, which dissolves in sulphuric acid, but which does not form alum unless a portion of potash be added to the solution. Thus, by the labours of Hellot, Pott, Baumé, and Margraaf, the nature of clay was completely developed. It was ascertained to be a mixture of alumina and silica, in variable proportions. It was shown, also, that it sometimes contained sulphuric acid, and not unfrequently potash. Hence the reason why, in some cases, it could be converted into alum by digestion in sulphuric acid, without the necessity of adding any potash to the solution. Modern chemists have added considerably to these facts. They have shown that chalk, felspar, mica, hornblende, oxide of iron, coal, bitumen, &c. are not unfrequently mixed with it; and that these additions alter its qualities considerably, and render it fit or unfit for the different purposes to which clay is usually applied.

Preparation of the clay, and formation of the brick.

3. Clay intended to be made into bricks ought to be dug out of the earth and exposed to the air and weather for a considerable time before it is employed. The longer this exposure is continued, so much the better will it be fitted for making bricks. This exposure answers a variety of purposes. If the stones, by the decomposition of which the clay has been formed, are not entirely decomposed, this exposure serves to complete the process, by promoting the disintegrating action of the air and rain. The exposure serves likewise to pulverize the clay, which is essential to the making of good bricks. We have little doubt that the same amelioration in the clay would be produced by simply drying it in the open air, and then grinding it to powder in a mill. By such a process the quality of the bricks would be prodigiously improved. Nor do we conceive that such an addition would greatly enhance the expenses of the brickmaker, at least in those districts where the mill could be driven by water.

When the clay has been reduced to powder, the next step is to make it into a stiff paste with water. Too much water should not be employed, because it is injurious to the strength of the bricks; and the utmost care should be taken to mix the whole of the clay as equally as possible with the water. If some parts of the paste be moister than others, it will occasion an inequality in the texture of the bricks formed of it, will render them apt to crack, and will greatly injure both their strength and their beauty. Hence the great importance of working the clay for a considerable length of time before moulding it into bricks. It is in this part of the process that we believe British brickmakers in general are most defective. As far as we have had an opportunity of witnessing the pro-

cess of kneading the clay, as conducted either in the neighbourhood of London or Edinburgh, we have always found a great sparing of labour. Hence we believe the reason why so many of the English bricks appear full of cracks, even when sold to the builder. Such bricks ought never to be purchased, as it is perfectly obvious that they cannot make a durable building.

The kneading of the clay is performed in some places by men's feet, in others by the feet of horses, and in others by machinery. The last method is undoubtedly the best; and we conceive likewise that it might be rendered the cheapest. It would be easy to devise machinery for kneading the clay, upon principles similar to those employed in mashing by the London porter brewers. And, if such a machine were driven by water, we conceive that it would not be nearly so expensive as either men or horses.

When the clay is sufficiently kneaded, it is moulded into the form of a brick, by being put into a very simple wooden mould; and the upper part of the brick is made smooth and even by cutting off the superfluous part with a wooden knife. The process is very simple, and is conducted by the workmen with great rapidity. A good brickmaker would mould about 5000 bricks in a day. He disengages the bricks from the mould by a gentle stroke on the back of the mould; and the wet bricks are at first arranged in rows upon long boards. When sufficiently dry to be handled, they are turned, and at last piled up in loose walls, which are thatched with straw to keep off the rain. In this position they are allowed to remain till they have become as dry as they can become in the open air.

In many cases the clay used for brick-making is destitute of the requisite quantity of sand. If such clay were made into bricks, it would shrink so much in their burning, that the bricks would lose their shape, and would probably crack in every direction. To prevent this, it is necessary to add a certain quantity of sand. This sand should not be very fine. It answers best when the particles are of such a size as to be readily distinguished by the naked eye. Even when as large as coriander seeds, it has been found to answer better than very fine sand. The brickmakers in the neighbourhood of London bring their sand from the bottom of the Thames near Woolwich, where it is raised by boats employed for that purpose, and brought up the river for the use of the brick-makers.

4. No general directions can be given respecting the quantity of sand to be mixed with the clay, because that depends upon the nature of the clay and upon the uses for which the bricks are intended. The more sand is added, the more accurately do the bricks retain their shape, and the less apt are they to crack during the burning, but at the same time their strength is diminished. Chemical lutes are often composed of four parts of sand and one part of clay. Such mixtures do not contract much in burning, and, therefore, are not apt to crack and drop off, which is the reason why chemists employ them. But they have not the adhesiveness of brick after being burned, and would not therefore answer the purposes of the brick-maker. In stone-ware the mixture consists of about four parts of clay and one of fine sand. It burns to a hard cohesive substance, capable of striking fire with steel. Such a proportion, then, in many cases would answer the purposes of the brick-maker.

The London brick makers make another addition to the clay, which we believe is peculiar to them. They add to every three parts of the clay about one part of the ashes from the fire-places of the city of London. These ashes contain some earthy matter; but they consist in a great measure of small coal unburnt and little altered, which has fallen through the interstices of the grate. The conse-

Brick.

quence is, that such a mixture, when sufficiently heated, takes fire and burns of itself, though very slowly; so that the London bricks are burned in a great measure by means of the fuel mixed with the clay of which they are composed.

It is essential to dry the bricks thoroughly in the open air before burning them; for when heat is applied to wet clay, the water which it contains being prevented from escaping by the adhesiveness of the mixture, is converted into steam, and cracks and breaks the mass of clay to pieces. Indeed, after the bricks are rendered as dry as they can become in the open air, they ought to be exposed at first to a gentle heat, which ought to be raised to redness very slowly, and in proportion as the moisture of the brick is dissipated. Water adheres with such obstinacy to clay, that it is never all driven off by the heat at which bricks are burnt. But the portion which remains is so intimately combined with the clay, as to constitute one solid mass, which has no great tendency to absorb an additional quantity of water.

Bricks are most commonly burnt in a kiln. This is a very simple structure, usually about thirteen feet long, ten and a half wide, and twelve feet high. The walls are one foot two inches thick, and incline a little to each other as they ascend. The bricks are placed on flat arches, having holes left in them like lattice-work. After the bricks are arranged on the kiln, to the number of about 20,000, they are covered with old bricks or tiles. Some brush-wood is then kindled in the kiln, and a moderate fire kept up till the bricks are rendered as dry as possible. The time required for this is two or three days; and the bricks are known to be dry when the smoke (which is at first black) becomes transparent. The mouth of the kiln is then filled up with pieces of brick and clay, leaving only room to introduce a faggot at a time. This structure at the mouth of the kiln is called a *shinlog*. The kiln is then supplied with faggots of furze, heath, fern, or whatever vegetable substance can be procured at the cheapest rate, till the arches look white, and the fire appears at the top. The fire is then diminished, and at length allowed to go out, and the kiln is permitted to cool. This burning process usually lasts about forty-eight hours.

The method of burning bricks in the neighbourhood of London is very different from this; and we do not know whether it be practised anywhere else. It obviously originated from the difficulty of procuring a sufficient quantity of vegetable matter to burn the enormous number of bricks consumed every year in London. If we consider the immense extension of houses which has taken place in London within the last fifty years, and if we consider that this vast city, containing nearly 1,500,000 inhabitants, is almost renewed every century, we may be able to form some notion of the prodigious quantity of bricks which it must consume. In the country round London there is a particular kind of clay, well known by the name of London clay. This clay is almost everywhere covered with a bed of gravel, which varies in thickness according to the elevation of the surface. Hence the whole of the country round London is fit for making bricks. Nothing more is necessary than to dig through the surface of gravel, and get to the clay.

We have already mentioned, that about a fourth part of the London bricks consists of small coal kneaded up along with the clay. When the bricks are sufficiently dry, they are piled up on each other in parallelopipedons to the intended height. Between each two rows of brick there is strewed a quantity of cinders, amounting to about three inches in thickness. At the distance of about nine feet from each other, perpendicular spaces are left, about a brick wide, which serve the purpose of flues. These

are made by arching the bricks over so as to leave a space between each about a brick in width. Over the whole is strewed a pretty thick covering of cinders. The flues are filled likewise with cinders, or, if they cannot be had, with coal. The fire-place is usually at the west end, and is generally three feet high. The fire, when once kindled in the fire-place, propagates itself very slowly through the whole *clamp*, as bricks piled in this manner are called. So very slow is the progress, that bricks in the neighbourhood of London take about three months in the burning. The heat is very intense, and, as the fuel is mixed up with the clay itself, every part of the brick is sure to be sufficiently burnt.

We conceive that the mixture of about one fourth of chalk with the clay of which the London bricks are made, would greatly improve their quality. The consequence would be an incipient fusion, which would render their surface much more compact and solid. The only difficulty would be to proportion the quantity of chalk so as to prevent complete fusion, which would run the bricks into each other, and destroy them entirely. Bricks made of materials which have undergone complete fusion would be greatly superior to common bricks. They would perfectly resist the action of the weather, and would, therefore, last much longer than common bricks. In Sweden it is customary at some of the iron founderies to cast the scoriæ into bricks, which they employ in constructing their furnaces. Such furnaces the writer of this article has seen; and he was assured by the gentleman who had the charge of the works, that they answered fully better than common bricks. It would be easy to make any quantity of such bricks in some of the large iron founderies of Great Britain. We are persuaded that such bricks might be brought into use for a variety of purposes with great advantage, and might even constitute a lucrative article of manufacture. Bricks made from the scoriæ of iron and copper founderies would vie in beauty with marble and porphyry, and would possess a lustre of surface to which few marbles could reach.

Few parts of Great Britain are so well adapted for the making of bricks, according to the London plan, as the neighbourhood of Newcastle-upon-Tyne. There the enormous heaps of small coal, which are of no use whatever, would furnish abundance of fuel at a much cheaper rate than even the London ashes; while the magnesian limestone that occurs in such plenty in the neighbourhood of Sunderland would enable the brickmaker to give the clay the requisite degree of fusibility.

As bricks form an article of taxation, and furnish a considerable revenue to government, their size has been regulated by act of parliament. They must not be less than eight and a half inches long, two and a half thick, and four inches wide. But, for various purposes, they are nevertheless made of very different and very considerable sizes.

Fire-bricks are made in the same way as common bricks, but the materials are different. The best clay for their composition is Stourbridge clay; and, instead of sand, it is usual to mix the clay with a quantity of old fire-bricks, or crucibles, or glass pots, reduced previously to powder. This mixture answers the same purposes as sand, while it does not communicate the tendency to fusion when it comes in contact with various fluxes that are communicated by siliceous sand.

There is a kind of bricks mentioned by Pliny as used by the ancients, which were so light as to swim in water.

“*Pitaneæ in Asia, et in ulterioribus Hispaniæ civitatibus Maxilua et Calento, fiunt lateres, qui ciccati non merguntur in aqua.*” (Plinii *Natur. Histor.* lib. xxxv. c. 14.) Pliny does not mention the part of the world in which the earth employed in the manufactures of these bricks was

Brick.

Brick
||
Brick-
layer.

found, though in all probability it could not be far from the cities where the bricks are said by Pliny to have been made. He says that the material employed was a kind of pumice stone. But it was quite unknown to the moderns, till, in the year 1791, Fabroni found a substance at Castel del Piano, not far from Santa Fiora, situated between Tuscany and the Papal dominions, which formed bricks capable of swimming in water. This is a white earthy matter, which constitutes a bed in that place, and was known in Italy by the name of *Latte di Luna*. In more recent mineralogical books it is distinguished by the name of *farina fossilis (bergmehl)*. Haüy considers it as a variety of talc, and Brochant as a variety of meersch-chaum. According to the analysis of Fabbroni this substance is composed of

Silica.....	55
Magnesia.....	15
Alumina.....	12
Lime.....	3
Iron.....	1
Water.....	14

100

But it has been recently analysed by Klaproth, who found its constituents,

Silica.....	79
Alumina.....	5
Oxide of iron.....	3
Water.....	12
Loss.....	1

100

We see from this analysis that this mineral is neither a variety of talc nor of meerschchaum. One would be disposed to consider it as a hydrate of silica; for both the alumina and oxide of iron are present in so small proportions, that we can scarcely consider them as in chemical combination.

Considering the composition of this earth, it is rather singular that it is capable of being agglutinated by a red heat. We rather suspect that the bricks of Fabbroni, which swim in water, have but very little strength. This, if it be the case, must greatly circumscribe their utility.

The colour of the London bricks is not red, as is the case with common bricks and tiles, but a light brownish yellow. This colour is more pleasing to the eye than common brick red, and on that account the London bricks are preferred for building houses. The brick-makers assign a curious enough reason for this colour. According to them, their bricks are kept as much as possible from contact with the air during their burning. The consequence of this is, that the iron contained in them is not oxidized to so great a degree as in common bricks. But this mode of reasoning is far from being exact. If air were excluded entirely, the bricks would not be burnt at all, because the fire would be extinguished. But if enough of air be admitted to burn the coal mixed with the clay, which must be the case, that air must also act upon the iron, and reduce it to the state of peroxide. Indeed, there can be no doubt that the iron in the London yellow bricks is in the state of peroxide as well as in the red bricks, for the peroxide of iron gives various colours to bodies, according to circumstances. We find bodies tinged with it red, yellow, and brown, according to the substances with which the oxide is combined. We ascribe the yellow colour of the London bricks to the ashes of the coals, which, by uniting with the peroxides of iron, form a kind of yellow ochre. (L.)

Brick-Layer, an artificer, whose business is to build with bricks, or make brick-work. The London brick-layers form a regular company, which was incorporated in 1568,

and consists of a master, two wardens, twenty assistants, and seventy-eight on the livery.

Brick-Laying, the art of framing edifices of bricks. Moxon has written a treatise expressly on the art of brick-laying, in which he describes the materials, tools, and methods of working, used by brick-layers.

Great care is to be taken that bricks be laid joint on joint in the middle of the walls as seldom as may be; and that good bond be made there as well as on the outsides. Some brick-layers, in working a brick and half wall, lay the header on one side of the wall perpendicular to the header on the other side, and so all along the whole course; whereas, if the header on one side of the wall were toothed as much as the stretcher on the other side, it would be a stronger toothing, and the joints of the headers of one side would be in the middle of the headers of the course they lie upon of the other side. If bricks be laid in winter, they ought to be kept as dry as possible; if in summer, it will save cost to employ boys to wet them, for they will then unite better with the mortar than if dry, and make the work stronger. In large buildings, or where it is thought too much trouble to dip all the bricks separately, water may be thrown on each course after they are laid. If bricks be laid in summer they must be covered; for if the mortar dries too hastily, it will not bind so firmly to the bricks as when left to dry more gradually. If bricks be laid in winter they should also be well covered, to protect them from rain, snow, and frost; which last is a mortal enemy to mortar, especially where it has been wetted just before the frost assaults it. See BUILDING.

BRIDE, a newly-married woman. Among the Greeks it was customary for the bride to be conducted from her father's house to her husband's in a chariot, the evening being chosen for that purpose to conceal her blushes. She was placed in the middle, her husband sitting on one side, and one of her most intimate friends on the other; torches were carried before her, and she was entertained on the passage with a song suitable to the occasion. When they arrived at the end of the journey the axle-tree of the coach they rode in was burnt, to signify that the bride was never to return to her father's house. Amongst the Romans the semblance of ravishing by force the bride from her mother, was kept up in memory, it is said, of the rape of the Sabines under Romulus. She was carried home in the night-time to the bridegroom's house, accompanied by three boys, one of whom carried a torch, and the other two led the bride, while a spindle and distaff were carried with her. She brought three pieces of money, called asses, in her hand to the bridegroom, whose doors on this occasion were adorned with flowers and branches of trees. Being there interrogated who she was, she answered *Caia*, in memory of *Caia Cecilia*, wife of Tarquin the elder, who was an excellent *lanifica* or spinstress; and for a singular reason, before her entrance, she lined the door-posts with wool, and smeared them with grease. Fire and water being set on the threshold, she touched both; but, starting back from the door, refused to enter, till at length she passed the threshold, being careful to step over without touching it. Here the keys were given her, a nuptial supper was prepared, and minstrels attended; she was seated on the figure of a priapus, and in this situation the attendant boys resigned her to the *promuba*, who brought her into the nuptial chamber and put her to bed. This office was performed by matrons who had only been once married, to denote that the marriage was to be in perpetuity.

BRIDEGROOM, a newly-married man, the spouse of the bride. In nothing have the usages of different nations varied more than in regard to marriage, and the ceremonies by which it is celebrated or solemnized. Amongst

Brick-
Laying
||
Bride-
groom.

Bridewell the Romans the bridegroom was decked to receive his bride; his hair was combed and cut in a particular form; he had a coronet or chaplet on his head, and was dressed in a white garment.

BRIDEWELL, a work-house, or place of correction for vagrants, and other disorderly persons.

BRIDEWELL, near Fleet-street, is a foundation of a mixed and singular nature, partaking of the characters of hospital, prison, and work-house. It was founded in 1553 by Edward VI., who gave the place where King John had

formerly kept his court, and which had been repaired by Henry VIII., to the city of London, with seven hundred marks of land, bedding, and other furniture. Several youths are sent to the hospital as apprentices to manufacturers, who reside there, and they are clothed in blue doublets and breeches, with white hats. Having faithfully served their time of seven years, they become entitled to their freedom, along with a donation of ten pounds each to enable them to carry on their respective trades.

BRIDGE.

THE mathematical theory of the structure of bridges has been a favourite subject with mechanical philosophers. It gives scope to some of the most refined and elegant applications of science to practical utility; and, at the same time that its progressive improvement exhibits an example of the very slow steps by which speculation has sometimes followed execution, it enables us to look forward with perfect confidence to that more desirable state of human knowledge in which the calculations of the mathematician shall direct the operations of the artificer with security, instead of following with servility the progress of his labours.

Of the origin of the art of building bridges something will be found in other parts of the work (see the article ARCH). The subject has been much discussed during the last half century, by some of the most learned antiquaries and most elegant scholars; but additions still more important have been made to the scientific and practical principles on which that art depends; and the principal information that may here be expected will be comprehended under the two heads of physico-mathematical principles, subservient to the theory of this department of architecture, and an historical account of the works which appear to be the most deserving of notice. The first head will contain three sections, relating respectively (1) to the resistance of the materials employed, (2) to the equilibrium of arches, and (3) to the effects of friction; the second will comprehend (4) some details of earlier history and literature, (5) an account of the discussions which have taken place respecting the improvement of the port of London, and (6) a description of some of the most remarkable bridges which have been erected in modern times.

SECT. I.—Of the Resistance of Materials.

A. *In all homogeneous solid bodies, the resistances to extension and compression must be initially equal, and proportional to the change of dimensions.*

The equilibrium of the particles of any body remaining at rest depends on the equality of opposite forces, varying according to certain laws; and that these laws are continued without any abrupt change, when any minute alteration takes place in the distance, is demonstrated by their continuing little altered by any variation of dimensions, in consequence of an increase or diminution of temperature, and might indeed be at once inferred as highly probable, from the general principle of continuity observed in the laws of nature. We may therefore always assume a change of dimensions so small, that, as in all other differential calculations, the elements of the curves, of which the ordinates express the forces, as functions of, or as depending on, the distances as abscissas, may be considered as not sensibly differing from right lines crossing each other, if the curves be drawn on the same side of the absciss, in a point corresponding to the point of rest, or to the distance affording an equilibrium; so that the ele-

mentary finite differences of the respective pairs of ordinates, which must form, with the portions of the two curves, rectilinear triangles, always similar to each other, will always vary as the lengths of the elements of the curves, or as the elements of the absciss, beginning at the point of rest; and it is obvious that these differences will represent the actual magnitude of the resistances exhibited by the substance to extension or compression. (Plate CXXXII. fig. 1.) (See Explanation of Plates at the conclusion of the article.)

It was on the same principle that Bernoulli long ago observed, that the minute oscillations of any system of bodies, whatever the laws of the forces governing them might be, must ultimately be isochronous, notwithstanding any imaginable variation of their comparative extent, the forces tending to bring them back to the quiescent position being always proportional to the displacements; and so far as the doctrine has been investigated by experiments, its general truth has been amply confirmed; the slight deviations from the exact proportion which have been discovered in some substances being far too unimportant to constitute an exception, and merely tending to show that these substances cannot have been perfectly homogeneous, in the sense here attributed to the word. When the compression or extension is considerable, there may indeed be a sensible deviation, especially in fibrous or stratified substances; but this irregularity by no means affects the admissibility of any of the conclusions which will be derived from this proposition.

B. *The strength of a block or beam must be reduced to one half, before its cohesive and repulsive forces can both be called into action.*

We must suppose the transverse sections of the body to remain plane and perpendicular to the axis, whatever the point may be to which the force is applied; a supposition which will be correctly true if the pressure be made by the intervention of a firm plate attached to each end, and which is perfectly admissible in every other case. Now, if the terminal plates remain parallel, it is obvious that the compression or extension must be uniformly distributed throughout the substance, which must happen when the original force is applied in the middle of the block; the centre of pressure or resistance collected by the plate acting like a lever, being then coincident with the axis. But when the plates are inclined, the resistance depending on the compression or extension will be various in different parts, and will always be proportional to the distance from the neutral point where the compression ends and the extension begins, if the depth of the substance is sufficient to extend to this point; consequently the forces may always be represented, like the pressure of a fluid, at different depths, by the ordinates of a triangle; and their result may be considered as concentrated in the centre of gravity of the triangle, or of such of its portions as are contained within the depth of the sub-

Bridge.

stance; and when both extension and compression are concerned, the smaller force may be considered as a negative pressure, to be subtracted from the greater, as is usual when any other compound forces are supposed to act on a lever of any kind. Now when the neutral point is situated in one of the surfaces of the block, the sum of all the forces is represented by the area of the triangle, as it is by that of the parallelogram when the plates remain parallel; and these areas being in either case equivalent to the same external force, it is obvious that the perpendicular of the triangle must be equal to twice the height of the parallelogram, indicating that the compression or extension of the surface in the one case is twice as great as the equable compression or extension in the other; and since there is always a certain degree of compression or extension, which must be precisely sufficient to crush or tear that part of the substance which is immediately exposed to it, and since the whole substance must in general give way when any of its parts fail, it follows that the strength is only half as great in the former case as in the latter. And the centre of gravity of every triangle being at the distance of one third of its height from the base, the external force must be applied, in order to produce such a compression or extension, at the distance of one sixth of the depth from the axis; and when this distance is greater than this, both the repulsive and cohesive forces of the substance must be called into action, and the strength must be still further impaired. (Plate CXXXII. fig. 2.)

C. *The compression or extension of the axis of a block or beam is always proportional to the force, reduced to the direction of the axis, at whatever distance it may be applied.*

We may suppose one of the inflexible plates attached to the extremities of the block to be continued to the given distance, and to act as a lever held in equilibrium by three forces, that is, by the cohesive and repulsive resistances of the block, and the external force; and it is obvious that, as in all other levers, the external force will always be equal to the difference of the other two forces depending on the compression and extension, or to the mean compression or extension of the whole, which must also be the immediate compression or extension of the middle, since the figure representing the forces is rectangular. And the effect will be the same, whatever may be the intermediate substances by which the force is impressed on the block, whether continued in a straight line or otherwise. When the force is oblique, the portion perpendicular to the axis will be resisted by the lateral adhesion of the different strata of the block, the compression or extension being only determined by the portion parallel to the axis; and when it is transverse, the length of the axis will remain unaltered. But the line of direction of the original force must always be continued till it meets the transverse section at any point of the length, in order to determine the nature of the strain at that point.

D. *The distance of the neutral point from the axis of a block or beam is to the depth, as the depth to twelve times the distance of the force, measured in the transverse section.*

Calling the depth a , and the distance of the neutral point from the axis z , the resistances may be expressed by the squares of $\frac{1}{2}a + z$ and $\frac{1}{2}a - z$, which are the sides of the similar triangles denoting the compression and extension (Prop. B.); consequently, the difference of these squares, $2az$, will represent the external force (Prop. C.) But the distance of the centres of gravity of the two triangles must always be $\frac{2}{3}a$; and, by the property of the lever, making the centre of action of the greater resistance the fulcrum, as the external force is to the smaller resistance, so is this distance to the distance of the force from the centre of action of the greater re-

stance; or $2az : (\frac{1}{2}a + z)^2 = \frac{2}{3}a : (\frac{aa}{12z} - \frac{a}{3} + z)$; Bridge.

and adding to this the distance of the centre of action from the axis, which must be $\frac{1}{2}a - \frac{1}{3}(\frac{1}{2}a + z) = \frac{1}{3}a - \frac{1}{3}z$,

we have $\frac{aa}{12z}$ for the distance of the force from the axis;

whence, calling this distance y , $z = \frac{aa}{12y}$.

E. *The power of a given force to crush a block is increased by its removal from the axis, supposing its direction unaltered, in the same proportion as the depth of the block is increased by the addition of six times the distance of the point of application of the force, measured in the transverse section.*

Since the compression or extension of the axis is inviolable, whatever the distance of the force may be, that of the nearest surface must be as much greater, by the properties of similar triangles, as the half depth, increased by the distance of the neutral point, is greater than that distance itself, that is, in the ratio of $a + 6y$ to a , since z is to a as a to $12y$ (Prop. D.), and to $\frac{1}{2}a$ as a to $6y$; and the strength is reduced in the same proportion as the partial compression or extension, by the operation of a given force, is increased. (Plate CXXXII. fig. 3.)

F. *The curvature of the neutral line of a beam at any point, produced by a given force, is proportional to the distance of the line of direction of the force from the given point of the axis, whatever that direction may be.*

Since the distance z of the neutral point from the axis is inversely as y , the distance of the force, and the radius of curvature, or the distance of the intersection of the planes of the terminal plates from the neutral point, must be to the distance z as the whole length of the axis is to the alteration of that length produced by the compression or extension, it follows that the radius of curvature must be inversely as the distance y , and inversely also as the compression, and the curvature itself must be conjointly as the force and as the distance of its application. If the direction of the force be changed, and the perpendicular falling from the given point of the axis on the line of the force be now called y , the distance of the force from the axis measured in the transverse section will be increased by the obliquity exactly in the same ratio as its efficacy is diminished, and the curvature of the neutral line will remain unaltered; although the place of that line will be a little varied, until at last it coincides with the axis, when the force becomes completely transverse: and the radius of curvature of the axis will always be to that of the neutral line as the acquired to the original length of the axis. (Plate CXXXII. fig. 4.)

G. *The radius of curvature of the neutral line is to the distance of the neutral point as the original length of the axis to the alteration of that length, or as a certain given quantity to the external force; and this quantity has been termed the modulus of elasticity.*

Or $r : z = M : f$, and $r = \frac{Mz}{f} = \frac{Maa}{12fy}$, as is obvious from

the preceding demonstration; y being the distance of the line of the force from the given point, whatever its direction may be.

H. *The flexibility, referred to the direction of the force, is expressed by unity, increased by twelve times the square of the distance, divided by that of the depth.*

Making the alteration of the axis unity, the corresponding change at the distance y will be to 1 as $z + y$ to z ,

or as $1 + \frac{y}{z}$ to 1, and will consequently be equal to

$1 + \frac{12yy}{aa}$ (Prop. D.)

Bridge. When the direction of the force becomes oblique, the actual compression of the axis is diminished, but its effect referred to that direction remains unaltered.

I. *The total compression of a narrow block, pressed in the direction of one of its diagonals, is twice as great as if the same force were applied in the direction of the axis.*

This proposition affords a simple illustration of the application of the preceding one. Calling the length of any portion of the axis x , beginning from the middle, and neglecting the obliquity, the distance of the force may be called $y = nx$; and the compression in the line of the force being everywhere as $1 + \frac{12yy}{aa}$, its fluxion will be

$$dx + dx \frac{12nxx}{aa}, \text{ and the fluent } x + \frac{4n^2x^3}{3a}, \text{ which, when}$$

$y = \frac{1}{2}a$, becomes $x + x$, which is twice as great as if y were always $= 0$. But if the breadth of the block were considerable, so that it approached to a cube, the compression would vary according to a different law, each section parallel to the diagonal affording an equal resistance, and the exact solution of the problem would require an infinite series for expressing the value of $\int n^{\frac{1}{2}} dx$.

K. *If a solid bar have its axis curved a little into a circular form, and an external force be then applied in the direction of the chord, while the extremities retain their angular position, the greatest compression or extension of the substance will ultimately be to the mean compression or extension which takes place in the direction of the chord, as $1 + \frac{4h}{a}$ to $1 + \frac{16hh}{15aa}$; a being the depth of the bar, and h the actual versed sine, or the height of the arch.*

We must here separate the actions of the forces retaining the ends of the bar into two parts, the one simply urging the bar in the direction of the chord, and the other, which is of a more complicated nature, keeping the angular direction unaltered; and we must first calculate the variation of the angular situation of the ends, in consequence of the bending of the bar by the first portion, and then the strain required to obviate that change, by means of a force acting in the direction of the middle of the bar, while the ends are supposed to be fixed. If each half of the bar were rectilinear, these two strains would obviously be equal, and would neutralize each other in the middle of the halves, which might be considered as the meeting of the ends of two shorter pieces, acting transversely or obliquely on each other, without any strain; the curvature produced by the whole strain being elsewhere as the distance from the line joining these points. But since the bar is supposed to be curved, it becomes necessary to determine the place of these neutral points, by calculating the change of its angular position throughout its extent.

Considering, first, the middle of the bar as fixed, and calling the angular extent of the variable arc x , beginning from the middle, and the radius r , the ordinate y , or the distance of the arc from the chord, will be $r \cos. x - b$, b being the cosine of the whole arc; and the fluxion of the change of the angular situation, being as the strain and the fluxion of the arc conjointly, will be expressed by $pr \cos. x dx - p b dx$, of which the fluent is $pr \sin. x - p b x$. In the second place, the curvature derived from the force acting between the two halves, when the ends are considered as fixed points, will be as $r - r \cos. x$, and the fluent of the change of angular situation may be called $qrx - qr \sin. x$; and at the end, when x becomes equal to

Bridge. c , the whole extent of the arc, these two deviations must destroy each other, since the positions of the middle and of the ends remain unaltered; consequently $pr \sin. c - p b c$

$$= qrc - qr \sin. c, \text{ whence } \frac{p}{q} = \frac{rc - r \sin. c}{r \sin. c - bc}, \text{ and the exact}$$

proportion of p to q may be found by means of a table of sines. But when the arc is small, $\sin. c$ being equal to

$$c - \frac{1}{6}c^3 + \frac{1}{120}c^5 \dots, rc - r \sin. c \text{ is } \frac{1}{6}rc^3, \text{ and } r \sin. c - bc$$

$= (r - b)c - \frac{1}{6}rc^3$; now $r - b$, the versed sine of the arc, becomes ultimately $\frac{1}{2}rc^2$, and $(r - b)c = \frac{1}{2}rc^3$; therefore $p : q = \frac{1}{6} : \frac{1}{2} = \frac{1}{3} : 1$; that is, the strain at the middle, expressed by p , must be half as great as the strain at the ends, expressed by q : consequently, when the force is considered as single, the distance of the line of its direction from the summit must ultimately be one third of the versed sine or height.

Now if we call any portion of the chord x , we have for the corresponding value of y , the distance from the line of direction of this force, $\sqrt{(r^2 - x^2)} - d$; and for the fluxion of the compression or extension in the direction of

$$\text{the chord, } dx \left(1 + \frac{12yy}{aa} \right), \text{ which will be true for both por-}$$

tions of the bar, whether y be positive or negative; but $y^2 = r^2 - x^2 + d^2 - 2d \sqrt{(r^2 - x^2)}$, and the fluent be-

$$\text{comes } x + \frac{12}{aa} \left(r^2x - \frac{1}{2}x^3 + d^2x - 2d [r^2 \text{ARC SINE } \frac{x}{r} - x \sqrt{(r^2 - x^2)}] \right).$$

When the arc is small, calling the whole versed sine h , we may have $y = \frac{1}{2}h - \frac{xx}{2r}$ and $y^2 = \frac{1}{4}h^2 - \frac{hx^2}{3r}$

$$+ \frac{x^4}{4r^2}, \text{ and the fluent is } x + \frac{12}{aa} \left(\frac{1}{4}h^2x - \frac{hx^3}{9r} + \frac{x^5}{20r^2} \right);$$

but when x becomes equal to the semichord c , h being $\frac{ce}{2r}$,

$$\text{the expression becomes } c + \frac{12}{aa} \left(\frac{c^5}{36r^2} - \frac{c^5}{18r^2} + \frac{c^5}{20r^2} \right)$$

$$= c + \frac{4c^5}{15a^2r^2} = c + \frac{16h^2c}{15a^2}, \text{ which shows the compres-}$$

sion or extension in the line of the chord, while c expresses that which the bar would have undergone if it had been straight, and the force had been immediately applied to the axis; the actual change being greater in the proportion of $1 + \frac{16hh}{15aa}$ to 1.

The greatest strain will obviously be at the ends, where the distance from the line of direction of the force is the greatest, the compression or extension of the surface being here to that of the axis as $a + 6y$ to a (Prop. E.), or

$$\text{as } 1 + \frac{4h}{a} \text{ to } 1; \text{ consequently the compression or exten-}$$

sion in the line of the chord is to the greatest actual

$$\text{change of the substance as } 1 + \frac{16hh}{15aa} \text{ to } 1 + \frac{4h}{a}.$$

Thus if the depth a were 10 feet, and the height or versed sine $h = 20$, the radius being very large, the whole compression of the chord would be to the whole compression of a similar substance, placed in the direction of the chord, as 5.267 to 1; and the compression at the surface of the ends would be to the compression of the axis there as 9 to 1; and, disregarding the insensible obliquity, this compression may be considered as equal throughout the bar, so that the compression at the ends will be to the compression of the chord as 9 to 5.267, or as 17 to 10.

Bridge.

Supposing, for example, such a bar of iron to undergo a change of temperature of 32° of Fahrenheit, which would naturally cause it to expand or contract about $\frac{1}{3000}$ in all its dimensions; then the length of the chord, being limited by the abutments, must now be supposed to be altered $\frac{1}{3000}$ by an external force; and, at the extremities of the abutments, the compression and extension of the metal will amount to about $\frac{1}{3000}$; a change which is equivalent to the pressure of a column of the metal about 3300 feet in height, since M , the height of the modulus of elasticity, is found, for iron and steel, to be about 10,000,000 feet; and such would be the addition to the pressure at one extremity of the abutment, and its diminution at the other, amounting to about five tons for every square inch of the section, which would certainly require some particular precaution, to prevent the destruction of the stones forming the abutment by a force so much greater than they are capable of withstanding without assistance. Should such a case indeed actually occur, it is probable that the extremities would give way a little, and that the principal pressure would necessarily be supported nearer the middle, so that there would be a waste of materials in a situation where they could co-operate but imperfectly in resisting the thrust; an inconvenience which would not occur if the bar were made wider and less deep, especially towards the abutments.

SECT. II.—Of the Equilibrium of Arches.

We may now proceed to inquire into the mode of determining the situation and properties of the curve of equilibrium, which represents, for every part of a system of bodies supporting each other, the general direction of their mutual pressure; remembering always that this curve is as much an imaginary line as the centre of gravity is an imaginary point, the forces being no more actually collected into such a line than the whole weight or inertia of a body is collected in its centre of gravity. Indeed the situation of the curve is even less definite than that of the centre of gravity, since in many cases it may differ a little according to the nature of the co-operation of the forces which it is supposed to represent. In reality, every gravitating atom entering the structure must be supported by some forces continued in some line, whether regular or irregular, to the fixed points or abutments, and every resisting atom partakes, in a mathematical sense, either positively or negatively in transmitting a lateral pressure where it is required for supporting any part of the weight; and when we attempt to represent the result of all these collateral pressures by a simple curve, its situation is liable to a slight variation, according to the direction in which we suppose the co-operating forces to be collected. If, for instance, we wished to determine the stability of a joint formed in a given direction, it would be necessary to consider the magnitude of the forces acting throughout the extent of the joint in a direction perpendicular to its plane, and to collect them into a single result; and it is obvious that the forces represented by the various elementary curves may vary very sensibly in their proportion, when we consider their joint operation on a vertical or on an oblique plane; although, if the depth of the substance be inconsiderable, this difference will be wholly imperceptible, and in practice it may generally be neglected without inconvenience; calculating the curve upon the supposition of a series of joints in a vertical direction. If, however, we wish to be very minutely accurate, we must attend to the actual direction of the joints in the determination of the curve, and must consider, in the case of a bridge, the whole weight of the structure terminated by a given arch-stone, with the ma-

terials which it supports, as determining the direction of the curve of equilibrium where it meets the given joint, instead of the weight of the materials terminated by a vertical plane passing through the point of the curve in question, which may sometimes be very sensibly less; this consideration being as necessary for determining the circumstances under which the joints will open, as for the more imaginary possibility of the arch-stones sliding upwards or downwards. But we may commonly make a sufficiently accurate compensation for this difference, by supposing the specific gravity of the materials producing the pressure, and the curvature of the line which terminates them, to be a little increased, while the absciss remains equal to that of the curve of equilibrium intersecting the joints.

L. If two equal parallelopipeds be supported each at one end, and lean against each other at the other, so as to remain horizontal, the curve of equilibrium, representing the general effect of the pressure transmitted through them, will be of a parabolic form.

The pressure of the blocks where they meet will obviously be horizontal, but at the other ends it will be oblique, being the result of this horizontal pressure and of the whole weight of each block. And if we imagine the blocks to be divided into any number of parts, by sections parallel to the ends, which is the only way in which we can easily obtain a regular result, it is evident that the force exerted at any of these sections by the external portions must be sufficient to support the lateral thrust and the weight of the internal portions; and its inclination must be such that the horizontal base of the triangle of forces must be to the vertical perpendicular as the lateral thrust to the weight of the internal portion; or, in other words, the lateral thrust remaining constant, the weight supported will be as the tangent of the inclination. But calling the horizontal absciss x , and the vertical ordinate y ,

the tangent of the inclination will be $\frac{dy}{dx}$; which, in the case

of a parallelopiped, must be proportional to the distance

x from the contiguous ends; and $x = \frac{m dy}{dx}$; consequent-

ly $x dx = m dy$, and $\frac{1}{2} x^2 = m y$, which is the equation of a parabola. It is usual in such cases to consider the thrusts as rectilinear throughout, and as meeting in the vertical line passing through the centre of gravity of each block; but this mode of representation is evidently only a convenient compendium.

If the blocks were united together in the middle, so as to form a single bar or lever, the forces would be somewhat differently arranged; the upper half of the bar would contain a series of elementary arches, abutting on a series of similar elementary chains in the lower half, so as to take off all lateral thrust from the supports at the ends.

With respect to the transverse strains of levers in general, it may be observed, that the most convenient way of representing them is to consider the axis of the lever as composed of a series of elementary bars, bisected, and crossed at right angles, by as many others extending across the lever, or rather as far as two thirds of the half depth on each side, where the centre of resistance is situated. The transverse force must then be transmitted unaltered throughout the whole system, acting in contrary directions at the opposite ends of each of the elementary bars constituting the axis; and it must be held in equilibrium, with respect to each of the centres, considered as a fulcrum, by the general result of all the corpuscular forces acting on the longer cross arms; that is, by the difference of the compression or extension on the different sides of the arms. This difference must therefore be

idge. constant; and in all such cases the strain or curvature must increase uniformly, and its fluxion must be constant; but if the transverse force be variable, as when the lever supports its own weight, or any further external pressure, the fluxion of the curvature must be proportional to it. Now the transverse force, thus estimated, being the sum of the weights or other forces acting on either side of the given point, the additional weight at the point will be represented by the fluxion of the weight, or by the second fluxion of the strain or curvature, which is ultimately as the fourth fluxion of the ordinate. Also the fluxion of the strain being as the whole weight on each side, it follows, that when the strain is a maximum, and its fluxion vanishes, the whole weight, or the sum of the positive and negative forces on either side, must also vanish; as Mr Dupin has lately demonstrated in a different manner.

M. *In every structure supported by abutments, the tangent of the inclination of the curve of equilibrium to the horizon is proportional to the weight of the parts interposed between the given point and the middle of the structure.*

The truth of this proposition depends on the equality of the horizontal thrust throughout the structure, from which it may be immediately inferred, as in the last proposition. The materials employed for making bridges are not uncommonly such as to create a certain degree of lateral pressure on the outside of the arch; but as there must be a similar and equal pressure in a contrary direction against the abutment, its effects will be comprehended in the determination of the point at which the curve springs from the abutment, as well as in the direction of the curve itself; so that the circumstance does not afford any exception to the general truth of the law. It is, however, seldom necessary to include the operation of such materials in our calculations, since their lateral pressure has little or no effect at the upper part of the arch, which has the greatest influence on the direction of the curve; and it is also desirable to avoid the unnecessary employment of these soft materials, because they tend to increase the horizontal thrust, and to raise it to a greater height above the foundation of the abutment.

We have therefore generally $\int w dx = mt = m \frac{dy}{dx}$, w being the height of uniform matter, pressing on the arch at the horizontal distance x from the vertex, t the tangent of the inclination of the curve of equilibrium, y its vertical ordinate, and m a quantity proportional to the lateral pressure or horizontal thrust.

N. *The radius of curvature of the curve of equilibrium is inversely as the load on each part, and directly as the cube of the secant of the angle of inclination to the horizon.*

The general expression for the radius of curvature is $r = \frac{(dz)^3}{dx d^2y}$; and here, since $m dy = dx \int w dx$, dx being constant, $md^2y = w(dx)^2$; but dz being $= dx \sqrt{1+t^2}$, $\frac{(dz)^2}{ddy} = \frac{m}{w} (1+t^2)$, and $r = \frac{m}{w} (1+t^2)^{\frac{3}{2}}$; and m being constant, r is inversely as the load w , and directly as the cube of the secant $\sqrt{1+t^2}$. The same result may also be obtained from a geometrical consideration of the magnitude of the versed sine of the elementary arc, and the effect of the obliquity of the pressure; the one varying as the square of the secant, the other as the secant simply.

O. *Consequently, if the curve be circular, the load must be everywhere as the cube of the secant.*

P. *If the curve of equilibrium be parabolic, the load must be uniform throughout the span.*

(Prop. L.) The uniformity of the load implies that the superior and inferior terminations of the arch, commonly called the extrados and intrados, should be parallel; but it is not necessary that either of them should be parabolic, unless we wish to keep the curve exactly in the middle of the whole structure. When the height of the load is very great in proportion to that of the arch, the curve must always be nearly parabolic, because the form of the extrados has but little comparative effect on the load at each point.

A parabola will therefore express the general form of the curve of equilibrium in the flat bands of brick or stone, commonly placed over windows and doors, which, notwithstanding their external form, may very properly be denominated flat arches. But if we consider the direction of the joints as perpendicular to the curve, it may easily be shown, from the properties of the wedge, that they must tend to a common axis, in order that the thrust may be equal throughout; and the curve must be perpendicular to them, and consequently circular; but the difference from the parabola will be wholly inconsiderable.

Q. *For a horizontal extrados, and an intrados terminated by the curve itself, which, however, is a supposition merely theoretical, the equation of the curve is*

$$x = \sqrt{m} \text{ HYP. LOG. } \frac{y + \sqrt{(yy - aa)}}{a}.$$

Since in this case $w = y$ (Prop. M.), we have $\int y dx = m \frac{dy}{dx}$, and $md^2y = y(dx)^2$; whence, multiplying both sides by dy , we have $mdy d^2y = y dy (dx)^2$; and, taking the fluent, $\frac{1}{2} m (dy)^2 = \frac{1}{2} y^2 (dx)^2$, and $mt^2 = y^2$, which must be corrected by making $y = a$ when t vanishes, so that we shall have $mt^2 = y^2 - a^2$, and $y = \sqrt{(a^2 + mt^2)}$. But since $\frac{dy}{dx}$

$= t = \sqrt{\frac{yy - aa}{m}}$, $dx = dy \sqrt{\frac{m}{(yy - aa)}}$, and $x = \sqrt{m} \text{ HL } (y + \sqrt{y^2 - a^2}) - \sqrt{m} \text{ HL } a$; whence all the points of the curve may be determined by means of a table of logarithms. But such a calculation is by no means so immediately applicable to practice as has generally been supposed; for the curve of equilibrium will always be so distant from the intrados at the abutments, as to derange the whole distribution of the forces concerned.

R. *For an arch of equable absolute thickness throughout its length, the equation is $z = \sqrt{(y^2 - m^2)}$ and*

$$x = m \text{ HL } \frac{y + \sqrt{(yy - mm)}}{m}.$$

The weight of any portion of the half arch being represented by its length z , we have $z = m \frac{dy}{dx}$; but $dz = dy$

$\sqrt{1 + \left(\frac{dx}{dy}\right)^2} = dy \sqrt{1 + \frac{mm}{zz}}$, and $dy = \frac{dz}{\sqrt{1 + \frac{mm}{zz}}}$
 $= \frac{z dz}{\sqrt{(zz + mm)}}$, of which the fluent is $\sqrt{(z^2 + m^2)}$, requiring no further correction than to suppose y initially equal to m ; and we have $z = \sqrt{(y^2 - m^2)}$. Again, since

$dz = dx \sqrt{1 + \frac{zz}{mm}}$, we find in the same manner $dx =$

$\frac{m dz}{\sqrt{(nm + zz)}}$, and $x = m \text{ HL } (z + \sqrt{mm + zz}) - m \text{ HL } m$

Bridge.

Bridge. $= m \text{ HL } \frac{z+y}{m}$. This curve will therefore in some cases

be identical with that of the preceding proposition. It is commonly called the catenaria, since it represents the form in which a perfectly flexible chain of equable thickness will hang by its gravity.

S. If the load on each point of an arch be expressed by the equation $w = a + bx^2$, the equation for the curve of equilibrium will be $my = \frac{1}{2} ax^2 + \frac{1}{12} bx^4$.

Since the whole load $\int w dx$ is here $ax + \frac{1}{2} bx^3$, we have $m \frac{dy}{dx} = ax + \frac{1}{3} bx^3$ (Prop. M.), and $my = \frac{1}{2} ax^2 + \frac{1}{12} bx^4$.

This expression will, in general, be found sufficiently accurate for calculating the form of the curve of equilibrium in practical cases; and it may easily be made to comprehend the increase of the load from the obliquity of the arch-stones. The ordinate y at the abutment being given, the value of m may be deduced from it; and since at the vertex my is simply $\frac{1}{2} ax^2$, the radius of curvature r will here be $\frac{xx}{2y} = \frac{m}{a}$.

T. If we divide the span of an arch into four equal parts, and add to the weight of one of the middle parts one sixth of its difference from the weight of one of the extreme parts, we shall have a reduced weight, which will be to the lateral thrust as the height of the arch to half the span, without sensible error.

The weight of the half arch being expressed by $ax + \frac{1}{3} bx^3$ when x is equal to the whole span, if we substitute x for $\frac{1}{2} x$, it will become $\frac{1}{2} ax + \frac{1}{24} bx^3$ for one of the middle parts, leaving $\frac{1}{2} ax + \frac{7}{24} bx^3$ for the extreme part, which gives $\frac{6}{24} bx^3$ for the difference of the parts, and one sixth of this added to the former quantity makes it $\frac{1}{2} ax + \frac{1}{12} bx^3$:

but since $my = \frac{1}{2} ax^2 + \frac{1}{12} bx^4$, dividing by mx , we have $\frac{y}{x} = \frac{\frac{1}{2} ax + \frac{1}{12} bx^3}{m}$.

It is also obvious, that if we subtract, instead of adding, one sixth of the difference, we have $\frac{1}{2} ax$; and dividing by $\frac{1}{2} x$, we obtain a , and thence $r = \frac{m}{a}$, m being previously found by the proposition.

U. When the load is terminated by a circular or elliptical arc, $w = a + nb - n \sqrt{(b^2 - x^2)}$ and $my = \frac{1}{2} (a + nb) x^2 - \frac{1}{2} nb^2 x \text{ ARCSINE } \frac{x}{b} - \frac{1}{2} nb^2 \sqrt{(b^2 - x^2)} + \frac{1}{6} n (b^2 - x^2)^{\frac{3}{2}} + \frac{1}{3} nb^2$.

The whole load $\int w dx$ is here $ax + nbx - \frac{1}{2} nb^2 \text{ ARCSINE } \frac{x}{b} - \frac{1}{2} nx \sqrt{(b^2 - x^2)}$; and hence $my = \frac{1}{2} ax^2 + \frac{1}{2} nbx^2 - \frac{1}{2} nb^2 x \text{ ARCSINE } \frac{x}{b} + \frac{1}{2} nb^3 - \frac{1}{2} nb^2 \sqrt{(b^2 - x^2)} + \frac{1}{6} n (b^2 - x^2)^{\frac{3}{2}} - \frac{1}{6} nb^3$ (Prop. M.) And the radius of curvature at the vertex will again be $\frac{m}{a}$. When the

curve is circular, the axes of the ellipse being equal, $n = 1$.

If the extrados and intrados are concentric, the calculation requires us to take the difference between the results determining the weight for each curve; but it will commonly be equally accurate, in such a case, to consider the depth of the load as uniform, at least when the joints are in the direction of the radii.

X. The abutment must be higher without than within, by a distance which is to its breadth as the horizontal distance of the centre of gravity of the half arch from the middle of the abutment is to the height of the middle of the key-stone above the same point.

This proposition follows immediately from the proportion of the horizontal thrust to the weight, determined by the property of the lever; the one acting at the distance of the height of the arch from the fulcrum, and the other at the distance of the centre of gravity from the abutment, so as to balance each other; and the oblique direction of the face of the abutment being perpendicular to the thrust compounded of these two forces. The same rule also serves for determining the proper position of the abutment of a beam or rafter of any kind, in order that it may stand securely, without the assistance of friction. But for a bridge, if we calculate the situation of the curve of equilibrium, we obtain the direction of the thrust at its extremity more conveniently, without immediately determining the place of the centre of gravity.

Y. In order that an arch may stand without friction or cohesion, a curve of equilibrium, perpendicular to all the surfaces of the joints, must be capable of being drawn within the substance of the blocks.

If the pressure on each joint be not exactly perpendicular to the surfaces, it cannot be resisted without friction, and the parts must slide on each other; this, however, is an event that can never be likely to occur in practice. But if the curve, representing the general pressure on any joint, be directed to a point in its plane beyond the limits of the substance, the joint will open at its remotest end, unless it be secured by the cohesion of the cements, and the structure will either wholly fall, or continue to stand in a new form. (Plate CXXXII. fig. 5.)

From this condition, together with the determination of the direction of the joints already mentioned (Prop. P.), we may easily find the best arrangement of the joints in a flat arch: the object, in such cases, being to diminish the lateral thrust as much as possible, it is obvious that the common centre of the joints must be brought as near to the arch as is compatible with the condition of the circle remaining within its limits; and it may even happen that the superincumbent materials would prevent the opening of the joints even if the centre were still nearer than this; but if, on the other hand, the arch depended only on its own resistance, and the materials were in any danger of being crushed, it would be necessary to keep the circle at some little distance from its surfaces, even at the expense of somewhat increasing the lateral pressure.

When the curve of equilibrium touches the intrados of an arch of any kind, the compression at the surface must be at least four times as great as if it remained in the middle of the arch-stones (Prop. E.), and still greater than this if the cohesion of the cements is called into action. In this estimate we suppose the transverse sections of the blocks inflexible, so as to co-operate throughout the depth in resisting the pressure on any point; but in reality this co-operation will be confined within much narrower limits, and the diminution of strength will probably be considerably greater than is here supposed, whenever the curve approaches to the intrados of the arch.

The passage of the curve of equilibrium through the

middle of each bloek is all that is necessary to insure the stability of a bridge of modern dimensions and of sound materials. Its strength is by no means increased, like that of a frame of carpentry, or of a beam resisting a transverse force, by an increase of its depth in preference to any other of its dimensions: a greater depth does, indeed, give it a power of effectually resisting a greater force of external pressure derived from the presence of any occasional load on any part of the structure; but the magnitude of such a load is seldom very considerable, in proportion to the weight of the bridge.

It is of some importance, in these investigations, to endeavour to trace the successive steps by which the fabric of a bridge may commonly be expected to fail. Supposing the materials to be too soft, or the abutments insecure, or any part of the work to be defective, and to afford too little resistance, the length of the curve of the arch being diminished, or its chord extended, it will become flatter, and consequently sink; the alteration being by far the greatest, if other things are equal, where the depth is the least, that is, near the crown or key-stone; so that if the curvature was at first nearly equal throughout, the crown will sink so much as to cause a rapid increase of curvature on each side in its immediate neighbourhood, which will bring the intrados up to the curve of equilibrium, or even above it, the form of this curve being little altered by the change of that of the arch. The middle remains firm, because the pressure is pretty equally divided throughout the blocks; but the parts newly bent give way to the unequal force, and chip a little at their internal surface; but being reduced in their dimensions by the pressure, they suffer the middle to descend still lower, and are consequently carried down with it, so as to be relieved from the inequality of pressure depending on their curvature, and to transfer the effect to the parts immediately beyond them, till these in their turn crumble, and by degrees the whole structure falls. (Plate CXXXII. fig. 6.)

SECT. III.—Of the Effect of Friction.

The friction or adhesion of the substances employed in architecture is of the most material consequence for insuring the stability of the works constructed with them, and it is right that we should know the extent of its operation. It is not, however, often practically necessary to calculate its exact magnitude, because it would seldom be prudent to rely materially on it, the accidental circumstances of agitation or moisture tending very much to diminish its effect. Nor is the cohesion of the cements employed of much farther consequence than as enabling them to form a firm connection, by means of which the blocks may rest more completely on each other than they could do without it; for we must always remember that we must lose at least half of the strength, before the cohesion of the solid blocks themselves, in the direction of the arch, can be called into action, and at least three fourths before the joints will have any tendency to open throughout their extent.

Z. The joints of an arch, composed of materials subject to friction, may be situated in any direction lying within the limits of the angle of repose, on either side of the perpendicular to the curve of equilibrium; the angle of repose being equal to the inclination to the horizon at which the materials begin to slide on each other; and the direct friction being to the pressure as the tangent of this angle is to the radius.

It is obvious, that any other force as well as that of gravity will be resisted by the friction or adhesion of the surfaces when its direction is within the limits of the angle at which the substances begin to slide; and it may be inferred from the experiments of Mr Coulomb and Profes-

sor Vinee, that this angle is constant, whatever the magnitude of the force may be, since the friction is very nearly proportional to the mutual pressure of the substances. The tendency of a body to descend along any plane being as much less than its weight as the height of the plane is less than its length, and the pressure on the plane being as much less than the weight as the length is greater than the horizontal extent, it follows, that, when the weight begins to overcome the friction, the friction must be to the pressure as the height of the plane to its horizontal extent, or as the tangent of the inclination to the radius.

This property of the angle of repose affords a very easy method of ascertaining, by a simple experiment, the friction of the materials employed. Taking, for example, a common brick, and placing it, with the shorter side of its end downwards, on another which is gradually raised, we shall find that it will fall over without beginning to slide; and when this happens, the height must be half of the horizontal extent, a brick being twice as long as it is broad. In this case, therefore, the friction must be at least half of the pressure, and the angle of repose at least 30° ; and an equilateral wedge of brick could not be forced up by any steady pressure of bricks acting against its sides, in a direction parallel to its base. But the effects of agitation would make such a wedge totally insecure in any practical case; and the determination only serves to assure us, that a very considerable latitude may be allowed to the joints of our materials, when there is any reason for deviating from the proper direction, provided that we be assured of a steady pressure; and much more in brick or stone than in wood, and more in wood than in iron, unless the joints of the iron be secured by some cohesive connection. It may also be inferred from these considerations, that the direction of the joints can never determine the direction of the curve of equilibrium crossing them, since the friction will always enable them to transmit the thrust in a direction varying very considerably from the perpendicular; although, with respect to any particular joint, of which we wish to ascertain the stability independent of the friction, it would be desirable to collect the result of the elements of which that curve is the representative, with a proper regard to its direction.

SECT. IV.—Earlier Historical Details.

The original invention of arches, and the date of their general adoption in architecture, have been discussed with great animation by Mr King, Mr Dutens, and several other learned antiquaries. Mr King insisted that the use of the arch was not more ancient than the Christian era, and considered its introduction as one of the most remarkable events accompanying that memorable period. Mr Dutens appealed to the structure of the eloacæ, built by the Tarquins, and to the authority of Seneca, who observes that the arch was generally considered as the invention of Demoeritus, a philosopher who lived some centuries before the birth of Christ, but that, in his opinion, the simplicity of the principle could not have escaped the rudest architect; and that, long before Demoeritus, there must have been both bridges and doors, in both of which structures the arch was commonly employed. There do indeed appear to be solitary instances of arches more ancient than the epoch assigned by Mr King to their invention. We find arches concealed in the walls of some of the oldest temples extant at Athens. The eloacæ are said to be arched, not at the opening into the Tiber only, but to a greater distance within it than is likely to have been rebuilt at a later period for ornament; and the fragments of a bridge, still remaining at Rome, bear an inscription which refers its erection to the latter

Bridge.

Bridge.

years of the Commonwealth. But it seems highly probable that almost all the covered ways constructed in the earlier times of Greece and Rome, were either formed by lintels, like doorways, or by stones overhanging each other in horizontal strata, and leaving a triangular aperture, or by both of these arrangements combined, as is exemplified in the entrance to the treasury of Atreus at Mycenæ, where the lintel has a triangular aperture over it, by which it is relieved from the pressure of the wall above; and this instance serves to show how different the distribution of the pressure on any part of a structure may be, from the simple proportions of the height of the materials above it. Some other old buildings, which have been supposed to be arched, have been found, on further examination, rather to resemble domes, which may be built without centres, and may be left open at the summit, the horizontal curvature producing a transverse pressure, which supports the structure without an ordinary key-stone. And this has been suspected to be the form of the roofs and ceilings of ancient Babylon, were Strabo tells us that the buildings were arched over, or "camerated," for the purpose of saving timber; and the bridge of Babylon, which must have been of considerable antiquity, is expressly said, by Herodotus, to have consisted of piers of stone, with a road formed of beams of wood only. It may however be rejoined, that though a dome is not simply an arch, yet it exceeds it in contrivance and mechanical complication; it generally exerts a thrust, and requires either an abutment or a circular tie; and it is scarcely possible that the inventor of a dome should not have been previously acquainted with the construction of a common arch. Besides the term CAMARA, the Greeks had also PSALIS, APSIS, and THOLUS, the last of which was particularly appropriate to circular domes; but the variety of appellations seems to prove that the thing must have been perfectly familiar; and the term PSALIS is supposed to have been applied from the appearance of the wedged arch-stones, viewed in their elevation, which could not have been observable in a dome of any kind.

From these outlines of the origin of the art of building bridges, we may pass on rapidly to the latest improvements which have been made in Great Britain and on the Continent in the practice of this department of architecture. A very ample detail of the most important operations that are generally required to be performed in it, may be found in the numerous Reports of the ingenious Mr Smeaton, published since his death by the Society of Civil Engineers in London. They contain a body of information comprehending almost every case that can occur to a workman in the execution of such structures; and even where they have to record an accidental failure, the instruction they afford is not less valuable than where the success has been more complete.

Respecting the general arrangement of a bridge, and the number of arches to be employed, in the case of a wide river, Mr Smeaton has expressed his approbation of a few wide and flat arches, supported by good abutments, in preference to more numerous piers, which unnecessarily interrupt the water-way. In a case where a long series of small arches was required, he has made them so flat, and the piers so slight, that a single pier would be incapable of withstanding the thrust of its arch; but in order to avoid the destruction of the whole fabric in case of an accident, he has intermixed a number of stronger piers, at certain intervals, among the weaker ones. Where several arches of different heights were required, he commonly recommended different portions of the same circle for all of them; a mode which rendered the lateral thrust nearly equal throughout the fabric, and had the advantage of allowing the same centre to be employed for all, with some

little addition at the ends to adapt it to the larger arches. He records the case of Old Walton Bridge, in which the wooden superstructure had sunk two feet, so as to become part of a circle 700 feet in diameter, and the thrust, thus increased, had forced the piers considerably out of their original situation; a striking proof that the principles of the pressure of arches must not be neglected, even when frames of carpentry are concerned.

Mr Smeaton particularly describes the inconveniences arising from the old method of laying the foundations of piers, which was introduced soon after the Conquest, and which was particularly exemplified in the old London Bridge. The masonry commenced above low-water mark, being supported on piles, which would have been exposed to the destructive alternation of moisture and dryness, with the access of air, if they had not been defended by other piles, forming projections partly filled with stone, and denominated *sterlings*, which, in their turn, occasionally required the support and defence of new piles surrounding them, since they were not easily removed when they decayed; so that by degrees a great interruption was occasioned by the breadth of the piers, thus augmented, requiring, for the transmission of the water, an increase of velocity, which was not only inconvenient to the navigation, but also carried away the bed of the river under the arches, and immediately below the bridge, making deep pools or excavations, which required from time to time to be filled up with rubble stones; while the materials which had been carried away by the stream were deposited a little lower down in shoals, and very much interfered with the navigation of the river. From these circumstances, as well as from the effects of time and decay, it happened that the repairs of the old London Bridge often amounted, for many years together, to £4000 a year, while those of Westminster and Blackfriars Bridges did not cost so many hundreds. It is true, that the fall produced a trifling advantage in enabling the London water-works to employ more of the force of the tide in raising water for the use of the city; and this right, being established as a legal privilege, long delayed the improvements which might otherwise have been attempted for the benefit of the navigation of the river. The interest of the proprietors of the water-works had been valued at £125,000, and it had been estimated that £50,000 would be required for the erection of steam-engines to supply their place; while, on the other hand, from thirty to forty persons, on an average, perished annually from the dangers of the fall under the bridge. (Plate CXXXIII. fig. 6.)
